Tomatoes diseased.—I am sending you some leaves of my Tomatoes, and I shall be very much obliged if you will tell me what is wrong with them? They are growing in a low span-roofed house, in which I had a splendid lot of Tomatoes last year. Every bit of the old soil was cleared out and fresh soil given them. I always keep a little warmth in the pipes at night, and on wet or cold days, and ventilate freely. They were planted about the middle of April, and the plants are very strong. I got some of the disease on a plant or two soon after they were planted, and I immediately gave them a thorough spraying with sulphate of copper, which appeared to kill the disease, only to appear again in a few days; since then I have tried several other mixtures and another spraying of sulphate of copper, with the same result. I started the plants in a manure hotbed, in one of which there was a very moist atmosphere. I think the plants are almost useless, therefore I have sown some more seed. Can you tell me how to clear the disease out of the house before putting in fresh plants? Would burning sulphur in the house kill it?—CONSTANT SUBSCRIBER.

[Your Tomato plants are suffering from a bad attack of Tomato disease (*Cladisporium fulvum*), for which there is unfortunately no known cure. This latter statement is amply verified by your own efforts to stamp out the disease, as the "stem" and leaves sent are eaten up with it, in spite of the heavy sprayings of sulphate of copper to which you have subjected them. Your only course is to root

The Mezereum (*D. Mezereum*). (See page 201.)

out the plants, burn them, and then subside your house to a thorough cleansing after clearing out the soil, following this up with a liberal whitewashing of walls and every particle of brickwork, using fresh slaked lime only for the purpose. Then put in a new bed of soil and procure good strong plants from an uncontaminated source, avoiding your own newly raised ones for this season, as they, by careful attention to cultural details, such as the maintenance of a buoyant, dry atmosphere at all times and ventilating liberally when the outside air is soft and halmy, and more carefully when the wind is chilly and blowing from a cold quarter, there is no reason why you should not yet obtain a full crop of fruit. The reply to your last query is in the negative, for, according to our experience, the burning of sulphur in the house is non-effective.]

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1. Miss E. Frank, Blackhurst, Tunbridge Wells, for Yellow Alyssum on an old terrace wall; 2. Miss Baylton, Oaklands, Dawlish, Devon, for Narcissus poeticus in Beech wood.

TREES AND SHRUBS.

CLIPPED COCKS AND HENS AT THE TEMPLE SHOW.

We noticed at this show an attempt to revive some of the worst features of the topiary "art" in the shape of Box and other bushes cut to eccentric shapes. This costly fad can only deceive those who practise it. We know one unfortunate man, with certainly more money than wit in this particular case, who ordered a lot of these things and put them in a garden by themselves. Half of them died, especially the variegated ones; the others are all kept to look at, and a more comical spectacle could hardly be seen, even among the scenic treasures of a penny gaff.

Fortunately, there are some old English gardens yet to be seen in the west country and elsewhere which show us the meaning of the practice—it was done, usually, to restrain a low bush or Yew which had grown a little too vigorous, and so was clipped into some shape. We warn our readers against over-indulgence in vegetable cocks and hens, usually imported from Holland and charged absurd prices for.

And here we may note the influence of the Dutch on English gardens. As to garden design, it was wholly evil in bringing their ideas of tree form into the garden. They allowed their noblest artists to starve, or even die in the workhouse—men whose pictures are now beyond price—and left their gardens to men who treated trees as so much green material to cut into walls, horrible to all who see the true and eternally settled natural forms of tree or shrub. Dutchmen are good nurserymen and bulb growers, and supply half Europe with their bulbs, but right taste in gardening is not among their possessions.

VARIEGATED TREES AND SHRUBS AT THE TEMPLE SHOW.

A very bad effect at the Temple Show arose from the undue prominence given to variegated shrubs in the open-air display. The nurseryman seizes every bit of variegation that occurs on a shrub and propagates it, and the result could be judged in the general effect of the avenue in the Temple Gardens. Nothing more spotty, formless, or ugly could well be seen. The half-diseased spotty things are shown in this way in order to get what nurserymen call "a bit of colour," and few of the really fine shrubs which our nurseries possess were seen in this mass. Not one out of forty of the shrubs we allude to can ever give any good effect in a garden or plantation, with the single exception, perhaps, of a good variegated Holly. It is deplorable that the society should encourage the exhibition of such poor things at its great summer show while our nurseries are full of handsome evergreen and other fine shrubs.

DAPHNE (GARLAND FLOWER).

ALPINE and mountain shrubs, some dwarf as well as beautiful, fragrant, and of the highest value for the rock-garden. Where the bushy rock-garden is made the larger kinds will be useful; the smaller may go with the choicer and more diminutive alpine plants. They are chiefly natives of Europe, and in cultivation do best when shaded in summer from the mid-day sun, and in winter screened from cold winds. If nurtured by the fallen leaves of trees they will grow with a vigour that we can scarcely hope to witness in our gardens under ordinary treatment. They have but few roots, and require to be transplanted when young. The best soil is a mixture of free loam and decayed leaf-mould, with some old road soil added. None of the Daphnes require a rich soil, and some of them even prefer old road soil to any other; this is especially the case with the Mezereum.

DAPHNE ALPINA (Mountain Mezereum).—A dwarf summer-leaving and distinct rock shrub, reaching 2 feet high, the flowers yellowish-white, silky outside, fragrant, in clusters of five from the sides of the branches. It is a low, branching shrubby flowerer from April to June, and bears round red berries in September. Central and S. Europe.

D. BAGAYANA (The King's Garland-flower).

—A dwarf alpine shrub, 3 inches to 8 inches high, of straggling growth, the leaves forming rosetta-like tufts at the tips of the branches, encircling dense clusters of fragrant, creamy-white flowers. It blooms in spring for several weeks, and thrives in the rock-garden in well-drained spots surrounded by stones or its wiry roots to ramble among. It is hardy, and in open spots thrives in any good soil; increased by layers pegged down in spring and separated from the plants as soon as roots are emitted.

D. CYNORUM (Garland-flower).—A little trailing shrub, growing from 6 inches to 10 inches high, and bearing rosy-lilac flowers, the unopened buds crimson, and so sweet that, where much grown, the air often seems charged with their fragrance. It is a native of most of the great mountain chains of Europe, and is one of the best of all plants for the rock-garden. It thrives in peaty and very sandy, moist soils, but in cold and stiff soils often fails. Wherever the soil is favourable it should be much used, and is usually increased by layers.

D. COLLINA (Box-leaved Garland-flower).—The leaves of this much resemble in shape and

There appear to be several varieties of *D. Genkwa*, some with much larger flowers than others, and some of a darker shade of purple. It is not quite hardy in cold districts. Syn., *D. Fortunei*.

DAPHNE HOTTETIANA (Van Houtte's Mezereum).—This singular kind forms a robust, spreading bush 3 feet or 4 feet high, with all the leaves collected on the young branches, while the old ones are naked. It is a distinct bush, quite hardy, flowering in the spring before the leaves appear, and is said to be a hybrid, which originated in one of the Belgian nurseries, between the common *D. Mezereum* and *Spurge Laurel*. Its leaves are from 3 inches to 3½ inches long and 1 inch broad, stained with purple on the upper side when fully developed, but when quite young and in the bud state of a dark purple colour. The shoots, when young, are also of a purple colour, but when old, light brown, stout, and spreading; the flowers are small, dark purple, quite smooth, and are borne along the shoots of the previous year, before the young leaves appear.

The King's Garland Flower (*Daphne Bagayana*) in the rock garden. From a photograph by Miss Wilhmott.

size those of the Balearic Box, the upper surface of a dark glossy green. The flowers are in close groups, and of a light lilac or pinkish colour, the tubes rather broad and densely coated externally with silky white hairs, which give the tubes a silvery appearance. It forms a beautiful, low, dense, evergreen shrub, the branches of which always take an upright direction, and form a level head, covered with masses of flowers from February to May. It is a native of Greece, South Europe, growing from 2 feet to 3 feet in height, and quite hardy. *D. vespertina* is probably a variety of it.

D. FROXIANA (Fion's Garland-flower).—A compact shrub not uncommon in gardens; the heads of bloom are in clusters, five fragrant flowers in each, of a pale lilac colour, the tubes densely covered externally with short, silvery hairs. This shrub flowers from March to May, and is hardy about London.

D. GENKWA (Lilac Garland-flower) is a summer-leaving shrub of from 2 feet to 3 feet in height, with downy branches and fragrant violet-coloured flowers thickly set on the leafless branches in early spring, giving the plant much fragrance of a small Persian Lilac.

DAPHNE MEZEREUM (Mezereum), a wild plant in English woods, is a charming and fragrant bush and the earliest to flower, often in February. Where the shrubby rock-garden is carried out nothing is more lovely for its adornment than a group of this. Though quite hardy, it is slow and not so pretty on some cold soils; but on such soils as we use on the rock-garden it will thrive. It is best to begin with little plants, and it is easily raised from seed.

D. OROKA (Sweet Daphne).—A fragrant and beautiful kind, in mild and southern districts hardy on the rock-garden. It is a greenhouse plant of exceptional merit when well grown. We know no fragrance more pleasant than that emitted by the pinkish flowers of this *Daphne*. Usually best on western aspects. There are varieties called *alba*, *rubra*, *Mazeli*, *punctata*. *Mazeli* is, according to Max Leichtlin, hardier than the older kind. Syn., *D. indica*. China.

D. RUPESTRIS (Rock Garland-flower) is a neat little shrub, with erect shoots forming dense, compact tufts, 2 inches high and 1 foot or more across, often covered with flowers of a soft-shaded pink in clustered heads. It is essentially a rock-plant, growing wild in fissures of

limestone in peaty loam, but is of slow growth, and it takes some years to form a good tuft. It seems to thrive in very stony and peaty earth with abundance of white sand, and should be planted in a well-drained but not a dry position.

D. STRIATA (Striated Garland-flower).—A sweet-scented hardy trailing species. It forms dense, twiggy, spreading masses, 1 foot to 3 feet across, which, in June and July, are covered with rosy-purple, scented flowers in clusters. The trailing and freely-spreading habit of this plant recommends it for covering bare parts of rock work. France.

GARDEN PESTS AND FRIENDS.

Fungus on Fir-tree.—I enclose specimen of Fir, the part of it appears to be in health, and the other part diseased. Kindly tell me its name, and what I can do to cure it.—**MRS. WALTER HILL.**

[The specimen of Fir which you enclose is attacked by a fungus which is by no means uncommon (*Peridermium elatinum*). Often curious abnormal growths known as "Wilches' Broom" spring from the gouty swellings. I do not know of any cure for this disease beyond cutting off the infested shoots and burning them. No application of any insecticide is of any use, as the fungus lives in the tissues of the shoots, and therefore cannot be destroyed by any outward application.—**G. S. S.**]

Insects on fruit-trees.—The enclosed leaves are from a Plum tree growing on a mud wall (thatched), and facing west. Almost all the young shoots are in a similar condition. I have tried syringing with insecticide, and also in the winter applied a Sunlight-soap wash, according to directions given in *GARDENING ILLUSTRATED*. The tree had very little blossom. Is the insect the common green-fly, and is there anything else I can do for that and for the Pear-tree (see enclosed leaves), eaten, I suppose, by caterpillars?—**R. J. STRIMMONS.**

[Your Plum-tree is not attacked by the common fly (that is, the green-fly of the Rose), but by a very similar insect—*Aphis pruni*. Cut off and destroy at once the badly-affected shoots, and syringe the others with a solution of paraffin-emulsion. Another year, as soon as the pest is noticed—and a sharp look-out for it should be kept—dip the ends of the shoots in the foregoing insecticide. Applying a wash of Sunlight-soap in the winter is of no use in such a case as yours. The Pear-leaves appear to have been eaten by some insect, and now to be infested by a fungus, which, however, is not in a condition that it is possible to name it. If you would kindly send some more specimens I might be able to tell you more about it.—**G. S. S.**]

Harvest-bug.—Can anyone tell me of anything which will prevent the attacks of this irritating insect? It is impossible to go into many of the gardens in the Carse of Gowrie (Perthshire) during the Gooseberry season owing to the virulent attacks of these tiny pests, which produce a most disagreeable irritation of the skin, not only on the face and hands, but all over, causing great discomfort for days.—**AN ANNUAL SUFFERER IN THE CARSE OF GOWRIE.**

[The fly you so-called "Gooseberry bug" is evidently, from your description, a small mite frequently known as "harvest-bugs" (*Leptus autumnalis*). It is said that dusting flowers of sulphur over the under garments will keep the mites away, and that rubbing the sulphur into the lites will kill the pests. Sulphur-ointment, paraffin-oil or formalin and water (I forget in what proportions)—the wet stopper or cork of the bottle should just touch the bits.

Have all been recommended by various persons, and no doubt are useful. Like many other insects, they seem to attack some persons more than others. While some suffer from these mites, others are hardly aware of their presence. Spraying the bushes with a solution of paraffin-emulsion would, no doubt, free the bushes from them; but these insects are so ubiquitous that you would be sure to pick up some from other plants.—**G. S. S.**]

Grubs on Apple-tree leaves.—I enclose specimens of curled-up leaves from various fruit-trees, a grub being in each. All the wall trees are attacked. I have tried hand picking, but fear it is impossible to kill all. Would Hellebore-powder do good, or would syringing with an insecticide be better? I am afraid nothing can get inside to kill the grubs, as the leaves are so tightly gummed together. Last year the Apple-trees were attacked with the same grubs, so, some six weeks ago, the trees and wall were syringed with blue-stone and soft-soap, 7 lb. of each to 40 gallons of water, and it is a great disappointment to find the pests as bad as ever. All the trees Apples, Plums, and Cherries—are at present covered with blossom.—**M. I. BYRAGE.**

[The leaves of your fruit trees are attacked by various insects. The most conspicuous were the caterpillars by the name of *Agrotis*.

(*Myzomenta padellus*). There were besides several specimens of the caterpillars of a small moth belonging to the family Tortricidae, or bell moths. The caterpillars of several species attack the leaves of fruit-trees, and it is difficult, as they are much alike, to be certain to which species they belong and on what kind of leaf a certain caterpillar was feeding, particularly when leaves of various kinds are packed together in the same box and the caterpillars crawl over them. The leaves were also infested by a number of aphides. Hand-picking is by far the most certain remedy, though tedious. Spraying the foliage with 2oz. of Paris-green (that sold as a paste is the best) and twice the amount, but in bulk, of fresh lime, mixed and kept well stirred in 25 gallons of water, or a solution of paraffin emulsion, would be useful, as they poison the leaves as far as the caterpillars are concerned, but they will not poison the aphides, though the paraffin emulsion will kill the aphides with which it comes thoroughly into contact. Hellebore would not be of much use. It would be better not to spray with any insecticide until the petals of the blossoms have fallen. In the winter (that is, any time between the fall of the leaf and the outer bracts of the buds showing signs of opening) it would be well to spray the trees with the caustic alkali wash so often referred to in these pages.—**G. S. S.**]

PLANTS AND FLOWERS.

OUTDOOR PLANTS

A GROUP OF MARGUERITES.

The illustration of a cluster of Marguerites (*Chrysanthemum frutescens*) represents a group

Group of Marguerites. From a photograph sent by Rev. G. W. Hall, Norton Vicarage, near Sheffield.

of these chaste and beautiful flowers in an old-fashioned vicarage garden in the North of England. From midsummer until autumn these bright blooms, with their snowy petals, form an excellent background for smaller and more showy plants. Their value for table decoration is well known. **G. W. HALL.**

Norton Vicarage, Sheffield.

BROWING DAHLIAS.

The end of May is the time to think of this important garden plant, and to make preparations for the year. An idea which has, I suppose, been handed down, but which is a wrong one, is that Dahlias require a very rich soil to grow properly. There are two points which I consider far more important—one is plenty of room, and the other proper thinning of the growth. Too rich soil produces an over-abundance of leafage, and when this is of a soft, sappy nature the blossoms are not of a satisfactory character. When planting Dahlias in a mixed border among other things, it is

well to cover each one at night by placing an inverted flower-pot over every Dahlia and taking the covers away during the day. PLANTING OUT.—Plant deep enough that when finished a saucer-shaped cavity may be left around each plant. This will give room for water later on, as the Dahlia delights in copious supplies. Secure each plant early by driving down a stout stake 4 feet long. Another advantage in staking early is to prevent damage to the growing bulb when left later. It must be remembered that a Dahlia plant will grow in an early autumn a big bush 4 feet through, although at this time it may be a small bit about the thickness of a lead pencil. Let the plants branch naturally, then begin to thin the shoots to form a well-balanced bush. The central stem will produce flower-buds early in July; perhaps these may be removed, as they rarely open well. Choose four to five side-growths, and each of these should have a stake, so that they may be securely tied early in their career. These growths, which soon gain the appearance of separate stems, with about three

shoots immediately under the bloom-buds on the central stem, are ample growths to provide a wealth of blossom to last until frost comes. Lateral shoots may be taken away—at least all those that tend to be in the way of the flowers. This item of thinning the growth is of the utmost importance. We frequently read in gardening papers of Dahlias not blooming, but of making all leaves. If this thinning of branches be followed such complaints would be rare, provided, of course, that other points, such as watering, have been attended to. Dahlias require plenty of water in dry weather, but one thorough soaking once or twice a week will do more good than a little each day. When the bloom-buds are forming liquid-manure is most beneficial. Take advantage, too, of showery weather by sprinkling fertilisers around the base of the plant to be washed down.

DISBUDDING.—Like other plants, Dahlias can be, and often are, over-budded. If, as some do, we concentrate the strength of the plant in the production of about half-a-dozen blooms, the chances are that they will open coarse and otherwise deformed. Even for exhibition it is well to allow from a dozen to eighteen blossoms to develop at the same time, besides other buds to follow. I am thinking now most of the Cactus varieties, the big double Dahlias require rather less in number, and the Pompons need not be disbudded. This is a very satisfactory class to grow, as they are so showy in the garden.

WATER FOR CERRISE. One fault the Dahlia has, and that is, it lasts more too well in a cut state. I have, however, found putting the stems into water immediately they are cut is a means of prolonging the flowers. When once the florets flag it is difficult to get them stiff again, but placing the stems into water prevents flagging to a great extent. If cut for exhibition I would prefer, the night before a show, placing the stems in water to a considerable depth. There is just one little matter that may be useful to exhibitors. The blooms take a month (as near as can be) to open from the dry soil state, and one may safely disbud accordingly.

PESTS. The pests most troublesome to Dahlias are earwigs, which may be trapped by placing an inverted flower pot filled with Moss or dry hay on the top of the stakes, and, of course, examining occasionally. Black and green aphids attack the plants in dry weather. A dusting of Tobacco powder and abundance of water at the roots will make the plants free from this.

VARIETIES. The following selections are quite up-to-date, and the sorts may be relied upon. A dozen Cactus Dahlias for exhibition: Mrs. J. J. Crowe, Lord Roberts, J. W. Wilkinson, Mrs. Carter-Payne, Up-to-Date, Uncle Tom, Britannia, Comaeopsis, J. E. Hulson, Vesta, Lucius, and Mary Service. A dozen for garden decoration: Standard Bearer, Mrs. J. J. Crowe, Mrs. Carter-Payne, Uncle Tom, Magnificent, Mary Service, Red Rover, Emperor, Britannia, Countess of Louisa, Loyalty, and Keyes White. Twelve Pompons for exhibition or the garden: Gannymede, Sunny Daybreak, Tommy Keith, Baculus, Emily Hopper, Geo. Brinkman, Douglas, Nerissa, Nelly Broomhead, Phoebe, Eurydice, and Whisper. A dozen show or large double Dahlias: John Walker, Arthur Rawlings, Victor, Duchess of York, Duke of Eife, Mrs. Gladstone, Colonel, J. T. West, R. T. Rawlings, Wm. Rawlings, David Johnson, and Warrior. H. S.

Tufted Pansy Mrs. E. A. Cade.—With the large number of rayless yellow Tufted Pansies now in commerce, it seems almost impossible to find much advance, and yet in the variety under notice we have a very beautiful representative of these charming flowers. The Tufted Pansy is essentially a plant for the hardy flower garden, and that its best characteristics should be appreciated it should have a dwarf, compact, or creeping-like style of growth, also a robust constitution, and, above all, should blossom freely, and the individual flowers should possess plenty of substance. Colour, of course, is all-important, and this should be bright and clear. In plants of the variety under notice *Digitized by Google*

heading habit, and the blooms are developed on stout erect footstalks, and are freely displayed. The colour is a very bright yellow with a neat orange eye, and the blossoms are sweet-scented.—W. V. T.

LILIUM ELEGANS AND ITS VARIETIES.

LILIUM ELEGANS, or *L. Taubergianum*, as it is also called, with its many beautiful varieties, may be regarded as among the choicest of the dwarf Lilies. The typical species, like many others, comes to us from Japan, and is quite as hardy and easily managed as most imported Lilies. For the most part dwarf, only a few kinds attaining more than 2 feet in height and not large or spreading in growth, these beautiful plants are well suited to grouping near the margin of a bed of peat-loving shrubs, where protection of leaf and branch is always helpful in the event of frost, and not less helpful below

L. elegans is that the root fibres are not persistent as some are, therefore they take less injury and suffer less from a lowered vitality when out of the soil, thus enabling would-be planters to safely plant these quite into the early spring months, when good bulbs are obtainable at a cheap rate. There are probably some two dozen varieties of this group, most of which are June and July flowering when established. Others, as for example *L. e. Batemanii*, is one of the finest forms of this group, and not only later-flowering but requiring a rather moister and more loamy soil. In the naturally sandy soils of Hampton, with a deep sub-soil of sunny gravel, this kind does quite well without any other preparation of the soil than old manure buried 6 inches or 8 inches below the bulbs. The following are the best kinds:—

ORANGE QUEEN, of which a couple of inflor-

Lilium elegans Orange Queen.

ground by reason of the many root fibres that encompass the bulbs, maintaining for them a moist condition of the soil when the bulbs are in their resting state. The same conditions may be given them in other ways, and in none more surely, perhaps, than by the preparation of a special bed for this tribe, with adequate drainage below a good bed of peat, leaf-mould, and loam, with a covering of sand over and under the bulbs. The soil must be in about equal parts, and of a depth of at least 18 inches. The idea of a bed done for these forms of *L. elegans* would not find much favour in gardens where the other alternative site would of a surety exist. The reason of a bed of these not being popular perhaps may, to some extent, depend upon their flowering period and the shortness of the season in the majority of instances. Again, as groups here and there in the foreground, these plants would be more at home and more natural looking. The amateur, too, with a cold greenhouse will also find them extremely useful as pot plants, and being dwarf and not more than 1 1/2 feet high in many instances, are particularly suited to the decoration of conservatory, sitting-room, or other apartment. In potting these forms of *elegans*, it should be remembered that a flowering bulb is no larger than a Walnut, and of such it were easy to get half-a-dozen in a 6-inch pot. The flowers, too, are not so strongly fragrant, hence their greater suitability to the purpose just mentioned. You can item more or less peculiar

essences appear in the illustration, is one of the newest forms and a great acquisition. The flowers are large and handsome, rich orange in colour, shading to warm apricot near the margin of the petals. The latter are broad and of great substance. Height 12 inches to 15 inches.

ANDREW WILSON is a kind not far removed in point of merit, but the flowers are of a more lemon shade, with a soft tone of apricot.

ALECTRUM, about 12 inches high, has pale apricot, abundantly-spotted flowers.

ATROSCINERUM is a richly coloured red, heavily spotted black form, often carrying four to six blooms.

MARMORATUM ATRUM, orange-yellow, with crimson spots, is a rather early-flowering kind, 18 inches high.

PRINCE OF ORANGE, apricot-yellow, dwarf, is very pretty for pots.

VAN HOPPER, a fine crimson, with very large, handsome flowers, is one of the most striking of this set.

WILSONI. This grows about 2 feet high, flowers large and cupped, apricot with many purplish spots streaked with yellow in the centre.

Other kinds are *Horsmanni*, blood-red; *fulgens*, deep red; and *sanguineum*, deep blood-red. E. J.

Late Sweet Peas.—Everyone acknowledges the value of Sweet Peas, and it is well known that the late-flowering varieties are those

earliest produced, as after cutting continuously for a few weeks, although there is no apparent diminution in the quantity of flowers, there is a decided change in the quality, the blooms becoming smaller. One may obviate this if, instead of sowing all the seed in the spring, some of it is left for sowing towards the end of May or early in June. Blooms from this late sowing will be found to come in during August and September, finer than those from the first sowing, and continue in good condition until out of all frosts. Many of my Sweet Peas sown in March of last year, and which suffered from the cold spring, did not furnish the best of blossoms, but from seed sown in June I gathered flowers of excellent quality in August and September.—LEAHURST.

THE FORMAL GARDEN.

TO THE EDITOR OF "GARDENING ILLUSTRATED,"

SIR, The advocate of the formal garden should delight in the garden of the Bello Isola, one of the Borronian Islands on Lago Maggiore. The gardener marched us through shrubberies and along terraces, firing off at us now and again the names of such familiar shrubs as *Magnolia grandiflora*, *Rhododendron ponticum*, *Azalea indica*, and the like. These, planted in single specimens as in a botanical garden, we smilingly acknowledged, and passed on in the hope that at any moment a turn in the path might reveal the wealth of flowers of an Italian spring. Patiently we mounted steps with stone balustrades leading up to a monstrous grotto-like erection. We gazed with awe at the weather-beaten statues, which seemed to invite a helping hand to speed them to a watery grave beneath. We survived the grotto and the statues, and became even more expectant as our guide led us towards a parapet, where he threw up his arms and beckoned us forward to gaze on some treasure beneath. Here, then, we should find the flowers. We reached the parapet, and peeped over, at the gardener's exciting invitation. "Jardin mosaïque—jardin mosaïque!" he cried. We gazed anxiously at the ample terrace beneath, lying in warm, southern sunshine and lapped by the waters of the lake. Here, in bright green grass, lay some half-dozen little wriggling beds of brown stones edged with white stones. "Jardin mosaïque" still haunted our ears like some shrill mockingbird as we turned sadly away. This, then, was the culminating effort of the designer of this island garden, situated in a climate that favours the growth of all things beautiful and choice.

The situation of this island garden is probably unique. It lies on the bosom of blue waters, that lie sparkling in a noble amphitheatre of mountains stretching in all directions as far as the eye can reach. It is an island in Fairyland—a complete realisation of the fairy stories of our childhood. It is a spot that may well give pause to the most skilful and thoughtful of gardeners. Here surely Nature might well be left to have her way, or, if gardening is to be done, the best of flowering shrubs should be massed together, and vigorous flowering climbers allowed to fling themselves down the rocks to the water's edge.

The formal gardener will plead that the "jardin mosaïque" was probably in relation to the building. To this assent may be heartily given. It would be impossible to say anything under or more appropriate about the château that stands like a hideous prison-house on one of the fairest spots of the earth.

SYDNEY SPALDINA

Baveno, Lago Maggiore.

NOTES AND REPLIES.

Delphiniums. It may seem to those unacquainted with the requirements of Delphiniums an exaggeration to say that they will do well in any soil and almost any garden, but such really is the case. They serve us best, however, when planted in deep loam, mixed with good stable manure, on a partly shaded border backed up by trees or on the margins of shrubberies, where their flowering spikes, in themselves conspicuous, are rendered more so by a leafy background. As a rule, there is a deficiency in most gardens of five flowers, but

in the Larkspurs we get lovely gradations of colour from palest blue to deepest shades of indigo, with rose and white intermingled. Room they must have, hence the necessity for planting them clear of other plants in order to show them off to the fullest advantage. To have good spikes of flowers one must not forget that they are moisture-loving plants, so that as the spikes throw up one should see that they enjoy copious supplies of water. Liquid manure, too, may be given them with advantage. They may be planted at any time from October to April. The propagation is readily effected by division of roots in the autumn, and owing to their rapid growth a large collection is acquired after a few years. The annual Larkspurs do not attain such large proportions as the perennial sorts; they are nevertheless very beautiful, and should be grown where room cannot be found for the taller growing varieties.—LEAHURST.

Hardy plants for edgings.—Where the system of summer bedding is practised, the matter of raising a sufficient quantity of dwarf plants suitable for edgings to beds and borders has to be considered every year, unless something is planted that is hardy. Ageratums and Lobelias are both pretty, but where arrangements cannot be made to propagate them at home, and they have to be bought, one finds out in a long border of what little use is a solitary dozen plants; indeed, in some places where all the "bedders" have to be purchased, edging plants have been dispensed with altogether. There is, however, another class of plants suitable for edgings, owing to their dwarfness, that only need once planting, and each year serve one's purpose. I refer to some of our hardy plants. A walk on either side of which Pinks are planted always looks neat, and has a charming effect when the Pinks are in bloom. So, too, are the white Arabis and the double and recently introduced form, *Arabis alba flore pleno*. *Cerastium Bierbersteinii* will be remembered by many as a plant often seen in rock gardens, but as an edging it has its advantages. Campanulas, which give us many that are tall and graceful, also furnish us with dwarf kinds that come to our aid for the purpose named. There is, for instance, *C. nitida* and *C. pumila*. *Cineraria maritima* is a plant also frequently to be seen in the rock garden, and its white foliage, even in the dreariest days of winter, is white; this makes a most useful subject for a finish to beds and borders. *Myosotis palustris*, which in June makes a charming change from the majority of plants used for this purpose, is easily propagated from cuttings.—WOOBASTWICK.

Spring bedding.—By the time this is at its best, which is generally by the end of April and early in May, it behoves the gardener to prepare for next year's display, so as to get good plants to put out in autumn. An early start is necessary with such things as Wallflowers, *Polyanthuses*, *Alyssum saxatile compactum*, *Myosotis*, *Anbrietias*, *Violas*, *Erysimum*, etc., all of which require a long season of growth to develop into strong, sturdy plants capable of withstanding the winter, and, with the exception of Wallflowers, I have found it is much the best plan to sow in boxes or pans, and keep in a cold frame until well through the soil, shading from the sun until this takes place, then place out-of-doors. Pick out into nursery lines in the open border before the plants have a chance to damp through overcrowding, allowing a space of 4 inches or 6 inches each way, or, better still, 8 inches between the rows, when a flat hoe can be frequently plied between. Winter must be applied during dry, hot weather, and *Polyanthuses* should be frequently syringed if red-spider attacks them. A north border is the best place for these, where they keep cool, and consequently more moist. Old plants of these may be lifted when out of bloom, laid in thickly together and well watered, dividing the same at the end of June, and planting when 6 inches apart in well-prepared ground. They will make serviceable stuff for autumn planting if well cared for in the matter of watering, etc., though seedlings make much the strongest plants as a rule. I consider the yellow variety is the most beautiful of all, but the seed must be got from a reliable source. *Polyanthuses* thrive best in fairly heavy loam. In light

sandy soils they soon fall a prey to red-spider, and require to be syringed with sulphur-water pretty often to keep them going.—J. M. B.

Flowers for autumn cutting.—We often go to a deal of trouble to make our gardens look smart in summer, but do not arrange for autumn-blooming plants. I have heard people occasionally express regret at being so late with Asters and Zinnias, and have seen them being pushed on in heat in April, as if everything depended on their being planted out the first week in May. Few think of sowing seed so late as May, but if we want a bright show on our warmest borders in October, then that is just the time when seed should be sown. We have, of course, some flowers that we always look forward to. There are, for example, outdoor Chrysanthemums that bloom in October, and which may be planted out during the present month. Where Cornflowers are grown, one is sure to have, in a sunny October, plenty of blossoms, and the *Coreopsis*, an annual which produces an abundance of gold and brown flowers, is a most persistent autumn bloomer. Sunflowers keep us company far on in the season, and some of the miniature sorts are excellent for cutting. Perhaps the best flowers we have are the Michaelmas Daisies. Few plants stand the frosts of autumn with so little harm to the blossoms as these. Autumn, too, brings us blossoms that we call everlasting. I am writing in a room where the bright red calyx of the Winter Cherries (*Physalis Alkekengi* and *P. Franchetti*) stand out conspicuously in a vase with Echinops, Eryngiums, and Statice, all gathered last October. I remember, too, how quite late in that month I gathered Gloire de Dijon and other late-flowering Roses, and how Dahlias that had been planted late had been placed on a warm border, and being somewhat sheltered, blossoms were gathered some time after others in a more exposed part of the garden had shown signs of frost. We may keep many flowers later than what we think if only we plant a little late, as in the case of annuals, and shelter the rest on the warmest borders.—LEAHURST.

Double Poet's Narcissus failing.—Can you tell me the cause of so many of my double Narcissus blooms not coming to perfection? I enclose some of the buds.—A. F. E. R.

[The so-called blindness in the double white Poet's Narcissus is a failing more or less prevalent each year, and is due to a variety of causes. This is a gross feeder, and therefore should be well manured. It prefers being planted deeply in the soil, not less than 6 inches, and preferably at 8 inches. A strong, almost tenacious soil is that most suited to its growth and flowering. In light soils, in conjunction with shallow planting, it is usually a failure. The bulbs are impatient of removal, and especially resent being dried off. When replanting is contemplated, this should be done in July, if possible. The root fibres of this kind are almost perpetual in character. Bulbs that have stood some time and flowered in the same spot have impoverished the soil, and failure is sure to follow. In such a case a winter mulching of manure would be helpful. Too often this is where the neglect comes in, though quite unwittingly. It is not sufficiently recognised that by reason of its late flowering the summer is approaching before the bulbs are fully ripened off. It is not generally known that the flowers that should appear in May of the present year are really formed and exist in embryo in midsummer in 1901. It is for this reason that every support should be accorded the bulbs, so that the growing season may be prolonged as much as possible, and thereby ensure the fullest development and the proper formation of the buds at this time. Not a few regard the "blindness," as this failing is called, as the result of the climatic or atmospheric conditions of the moment, but the true cause is more probably insufficient development in the previous year, as even though blind all the other parts may be good, and as such are produced by the bulb in its season. All you can now do is to encourage the most vigorous growth by mulching with manure and a good dressing of soot, and at least weekly applications of liquid manure. In digging in the manure cow manure and soot are best if your soil is light—keep it 4 inches or 6 inches below the bulbs.]

ROOM AND WINDOW.

ON FLORAL DECORATION.

On July 27th, last year, an article appeared under the above heading, the writer of which was very severe on the exhibitors and judges at Rose-shows. It was asserted that those who exhibited Roses in the conventional stands in vases at shows could not by any possibility have a real love for flowers, and, further, that anyone who could become enraptured with a show bloom was incapable of recognising the "wayward beauty" of naturally-growing Tea

classes for the so-called "garden Roses," artistic arrangement is possible, but until this method obtains with the "show bloom" classes the exhibitor is powerless to make any alteration, however much he may desire to do so. The statement that the admirer of, let us say, the champion bloom at the National Rose Society's show necessarily ignores the charm of the blossom-laden sprays of our garden Roses attributes to the individual in question a decidedly limited intelligence. Personally, though I delight in gazing at the graceful vigour of the growing Tea Roses, with the tender colouring of their buds and half-expanded

correspondent deservedly derides the hackneyed formula that such things are "only matters of taste," a statement that "if it were confined to the ignorant would do but little harm, but we hear it expressed by men of education." It is not a question of taste, but a question of right and wrong. Bad judging in this department means ignorance both of the first principles of artistic training and of the truth and beauty of natural expression. I have often wished that judges of floral decorations would affix to each exhibit a plainly-written card stating their reasons for awarding or withholding the prizes, and have myself been sorely tempted to do so when judging in these classes. I recognise, however, that such a practice would do, probably, more harm than good, for where the judgment was faulty the public would be led to form an erroneous estimate of the ideal to be aimed at. To those who have thoroughly studied the floral arrangements staged for competition at many shows, it is evident how little beauty of colour and form is comprehended by many of the exhibitors. The beheaded Lilies mentioned by your correspondent offer a case in point, and as to Crimson Rambler Rose, the man who could employ this crinoid and had colour for a dinner-table would doubtless be equal to making a funeral wreath of Nasturtiums. Instances such as these are, unfortunately, to be met with at almost every exhibition where cut flowers are staged for effect. Many competitors appear to enter the show room with little or no idea of the design which they are about to work out, but such conceptions are rarely satisfactorily evolved on the spur of the moment. Not having considered a plan beforehand, the operator frequently finds it difficult to know where to stop, and continues ailing until what might have been an artistic creation is hopelessly burdened by superabundant material. Time after time, while watching the arrangers at their work, have I seen this happen.

Colour as well as form often proves a stumbling-block. It may be laid down as a general rule that the fewer the colours the better will be the effect. Green is necessarily present in every case, except in arrangements of autumn foliage, as is white in the majority in ninety-nine cases out of a hundred, the hundredth occurring where the polished mahogany, shining like a mirror, is left uncovered to reflect the silver and crystal, but this exception is naturally absent in competitions. Green and white being present, white flowers may be employed without adding another colour, and with these may be associated a third tint, vivid or subdued according to the arranger's discretion, a combination affording every possibility of an artistic creation. An association of bright colours in allied tints, such as red, orange, yellow, and sulphur, may be successfully carried out, but care must be taken that no discordant hue is admitted. I once saw a glaring arrangement of autumn foliage and scarlet, orange, and yellow flowers entirely spoil by the introduction of blossoms of the pink Cosmos, the pink being of a cold tint that held a suggestion of blue, and thus destroyed the sense of harmony. Colour harmonies are generally preferable to contrasts, though these may oftentimes be charming. Associations such as the scarlet Euphorbia jacquiniiflora and Paper-white Narcissi, the steel-blue Sea Holly and orange Alstromeria, white Lilies and the lavender Frigeron speciosus, or the same Lilies with the fawn-brown Day Lily, white Galega and blue Cornflowers, and the gentian-blue Salvia patens and sulphur Paris Daisies, all form pleasing contrasts, but the latter must not be employed at night, as under artificial light the blue of the Salvia turns to purple-black. Floral arrangements owe much to the nature of the

materials employed. These should be simple in form and subdued in colour, for, as in the rock-garden, the sole mission of the stones should be to present the plants to the best advantage, so the vases used to contain the flowers should be such as not to distract attention from the flowers themselves. Heavy camlelaba, bowls of gold-fish, mirrors representing sheets of water, on which mimic swans repose, and massive cypresses, though suitable for a civic banquet, are altogether out of place on a small table. Spilery centre-pieces covered with gold tinsel, now too often seen, are a lamentable failure. Other wise artistic arrange-

Flowers of Chinese Lily Tree in old China bronze vase.

Roses. Now, the fallacy of arguments such as these does more harm than good to the cause of "artistic floral arrangement." It will be admitted that the present method of staging Roses at shows is far from being artistic; but the end in view is not the production of a pleasing general effect, but the display of the flowers in the manner best calculated to afford the judges the opportunity of arriving at the merits of every individual bloom. The chief object of the exhibitor is to win the prize, and to do so he must conform to the rules and regulations. Directly he strikes out a line of his own he is disqualified by the

flowers, set off by the bronze tints of the young foliage, the sight of a perfect show bloom of Comtesse de Nadailac also gives me pleasure, and so, I think, it is with others. Mistakes more often occur in judging floral arrangements at shows than in any other section. Sometimes this is owing to the awards being made hurriedly, but even when serious attention is given the result is not necessarily better, but often worse. Almost everyone considers himself or herself competent to judge "floral decorations," but, as a matter of fact, the number of those who are really competent is extremely limited. Your

ments are sometimes entirely spoiled by the accessories employed. I remember a table which, so far as form and colour of the floral design were concerned, was distinctly meritorious. The flowers consisted of *Gloriosa superba* and white *Bouvardia*, while Maiden-hair fronds and *Smilax* were used with discretion. The lawn-orange of the *Gloriosa* contrasted well with the white of the *Bouvardia* and the cloth, but the effect was entirely marred by a pedestal of vivid blue on which the centre-piece stood, and by ribbons of the same colour which adorned two white china vases. Those who are anxious to become experts in artistic floral decoration cannot do better than study

THE METHODS OF THE JAPANESE, in which recognition of the value of simplicity and sympathy for beauty of form are strikingly patent. As a nation the Japanese have for generations regarded the arrangement of cut flowers as a high art, and many exhaustive treatises have been written on the subject by the leaders of the cult. Few if any of our own countrymen have mastered the intricate and symbolic styles of arrangement practised by the different schools of Japanese floral artists, but the simplest form is tolerably familiar to us now. This consists of three shoots or flower-sprays, the centre one being tall and straight, that on the one side sweeping horizontally outward at half the height of the central shoot, and that on the other side much shorter than the others, bending slightly outward from the centre. To these three distinct parts, as to every portion of more important compositions, traditional meanings are attached, but while we need not trouble ourselves as to the touch, we may well take to heart the lesson of rigidly limiting the number of components employed. A few blossoms of one species of wild flower mixed with field grasses or long-stemmed Tea Roses arranged with their own foliage will afford greater pleasure than pretentious displays, to provide which stove and Orchid-house have been ransacked.

FLOWERS AND FOLIAGE. Flowers should, if possible, be arranged with their own foliage. In some cases, however, they are leafless at their blossoming time, and in others cutting the leafage would prove injurious to the plants, in either of which events it is necessary to substitute other foliage; thus *Belladonna Lilies* arrange well with the somewhat similar leaves of the *Gladwin* (*Iris foetidissima*), glowing Ghent Azaleas are set off to perfection by the crimson maroon foliage of the *Sycamore* suckers, which spring up so thickly around the tree-holes, single *Poppies* associate charmingly with wild oats, and a flowering branch of wild Cherry is fittingly supplemented by emerald green Larch sprays. In judging table decorations the general effect should first be studied, and this can be more accurately determined from a little distance than close at hand. The difference between light and graceful and heavy, overburdened arrangements then becomes instantly apparent, as well as the trivial appearance presented by numbers of little flower-glasses and the sombrel aspect produced by overmuch hanging greenery. When a conclusion has been arrived at on the question of general merit a close inspection becomes necessary in order to ascertain if the exhibits are marred by any blemishes that would catch the eye of one sitting at the table, though unnoticeable further off, such as a discoloured petal, a withered leaf, or the evident use of wire, all of which should tell heavily against a prize.

S. W. F.

Araucaria excelsa for furnishing.—Few green-leaved plants are so useful in pots for furnishing as this *Araucaria*. Its enduring nature is wonderful. I have a plant now in good health that a lady had in a drawing-room in London for nearly twelve years. Having bought it quite a small plant, and being naturally fond of gardening, she cherished this in a way only such people do. When it got into bad health and was very leggy it was sent to me, asking me if anything could be done with it. When it came into my hands I saw it had some good leafage at the top. It was shaken out, roots washed, and potted into a very small pot, placing it in a growing temperature, and now after two years it has made capital growth, with branches 3 feet 10 inches long.

small pots this *Araucaria* is very useful for the dinner-table, as quite large plants can be grown in small pots. At one time I had a pair 18 feet high, growing in 14-inch pots, and now I have a perfect specimen in a 10-inch pot 8 feet high. In a dark corner I had for eight months one that had lost its top by accident. A little manure-water keeps the plants going wonderfully in small pots. —J. Crook.

ROSES.

A BEAUTIFUL NEW RAMBLER ROSE.

We now and then get a very good novelty in the way of Roses from the United States. Dorothy Perkins is the latest comer. The charming little double shell-pink flowers as they open remind one of the miniature *Provence De Meaux*, only that they are brighter and rather larger. They are produced in splendid clusters of twenty to fifty flowers. One can imagine, therefore, the effect obtained from a well-developed plant. Growths are made in one season of 10 feet to 12 feet long. Although this new Rose was raised from *Rosa Wichuriana*, crossed with the old H.P. Rose *Mme. Gabriel Luitet*, it loses the procumbent form of the seed parent, and, instead, partakes of the upright habit of *Crimson Rambler*, so that it is a first-rate companion of this latter. Being a Rose of such a vigorous habit, one would suppose that it would not be suitable for pots except in pillar form; but that is not so. Plants potted since January and pruned back to within 1 foot 6 inches of their base are now yielding ten or twelve trusses of lovely little blossoms, so that it makes a most elegant and valuable pot plant. The foliage is almost evergreen, and resembles that of *R. Wichuriana* in some degree, except that it is not quite so glaucous. Unlike most of the Rambler section, Dorothy Perkins possesses a very pleasing fragrance, which it doubtless inherits from the pollen parent. If this very valuable running Rose (*R. Wichuriana*) is capable of such a beautiful development, our gardens will soon be enriched with a race of elegant climbers. And who knows but that in time we shall impart to them a perpetual-flowering tendency? Most of the hybrids of *R. Wichuriana* are just as beautiful when growing upon pergolas or twining over fences and arbors; but the type certainly looks out of place when planted in such positions.

Two other members of *R. Wichuriana* exhibited at the Temple Show recently attracted much attention. They were *Aberic Barbier* and *Reue Andre*, both carrying buds almost tree-like in character and refinement.

Guss.

MILDEW ON ROSES.

In some gardens both outdoor Roses and those grown under glass would seem unable to resist mildew, and it is only by persistent applications of some favoured fungicide that clean plants can be maintained. Very much, I think, depend on the structure in which they are grown. In my own case it needs constant effort to maintain a freedom from mildew as regards pot-grown Roses, while, at the same time, climbing Roses in fruit-houses never show a trace of mildew from one end of the year to the other, no matter what the weather or the time of year may be. There are some which are started into growth very early in January, others follow in rotation, but in each case no trouble is experienced from these roof-grown Roses. In pots the case is different, for, stood on the floor of the same house, they would not make 6 inches of growth before mildew asserted itself. Outdoors, mildew gives us no trouble. During the course of a brief visit and conversation with Mr. Crook, at Forde Abbey, I had an object lesson as to the value of paraffin emulsion for staying mildew on outdoor Roses. Against the end of one of his glass-houses were trained some Roses, and, for the purpose of experiment, Mr. Crook had prior to my visit given a portion of these Roses a dressing of paraffin emulsion and warm water, other portions being left untouched. The dressed and undressed portions of the trees made the influence of this now popular insecticide apparent. The same experiment

was carried out indoors, and the results were equally favourable.

As a general rule, sulphur enters largely into the composition of mildew specifics, and is more often used alone for mildew on *Roset* and other subjects liable to its attack. Certainly the effect on mildewed leaves of a dressing of paraffin emulsion was very marked. In its use, however, there is this important necessity that it be applied early, or even before there is evidence of mildew. W. S.

NOTES AND REPLIES

Tea Rose *Mme. Berkeley*.—To those who like a Rose in the bud state this new kind is exceedingly pretty. The bud is very long and the petals well arranged, but it opens to a semi-double flower only. As a pot-Rose this variety may be recommended, the habit of the plant being free and branching. —S.

Some very handsome blooms of this Rose, rivaling *Niphotos* in purity of colour when grown indoors, were shown by Messrs. Paul and Son at a recent meeting of the Royal Horticultural Society. We understand that the blooms shown were part of the second crop this year. It was given an award of merit in September of last year. —Ed.]

Pruning *Marechal Niel* Rose.—Some years ago when I grew this Rose in quantity under glass I always cut back the trees almost to the ground line after flowering, and depended on entirely new growth for the following season. But whether the after treatment was different or not from that of others I do not know. I have never seen the practice so successfully followed since. Anyhow, in a number of instances since, I have seen bad results from the method. Instead of breaking away freely, the plants become cramped and debilitated, too much of the life seems to be taken from them. The plants must be thinned so that their growth immediately after flowering, else they become an entangled mass, which eventually gets pung and weak. I would prefer to cut out the older branches entirely rather than shorten the younger ones, and thereby have a supply of youthful growth. What I would especially guard against is mildew. This readily attacks tender shoots, and is usually the result of cold draughts. Little air and ample moisture are what Roses under glass require; the growth then seems to mature too fast for the pests to harm. This popular Rose blossoms best on long growths of the previous year, so that our efforts should go to the production of these. The young growths may be thinned so that each shall have room to extend, and be trained under the glass where the abundant light will mature the wood properly. —H. S.

Climbing Roses for low walls.—Will you kindly give me the names of about two dozen different varieties of wall Roses? There are three walls, about 6 feet high, with south, west, and north aspects. Perhaps you can say what varieties would do best under the north wall particularly? —M. W. K.

[A selection for low walls can best be made from what are known as half-climbers. If you planted Roses of the type of *Rosa d'Or* you would have your wall covered quickly but obtain very little blossom, simply because such Roses require walls some 18 feet to 20 feet in height to enable them to fully develop their beauty. Of course, one may train these strong growers horizontally, but the result is not always satisfactory. By selecting the less vigorous kinds the wall is not covered so quickly, but you obtain blossom from the commencement, and each year the plants widen in proportion to their upward growth. We have known plants of *Marie Van Houtte* and *Anna Ollivier* cover even 10-foot walls, and Roses of the *La France* race will make a lot of growth so cultivated. The kinds which we would recommend for your different walls are as follows:—South wall: *Billiard et Barre*, *Mme. Abel Chatenay*, *Hermine Trochon*, *Mme. Wagram*, *Belle Lyonnaise*, *Mme. Lambert*, *Celine Forestier*, and *Maman Cochet*. West wall: *Gross* an *Teplitz*, *Houquet d'Or*, *Marie Van Houtte*, *Mons. Desir*, *W. A. Richardson*, *Safrano*, *Longworth Rambler*, and *Mme. Juliet Siegfried*. North wall: *Cheshant Hybrid*, *Pink Rover*, *Ulrich Brunner*, *Caroline Testout* (General Jacqueminot), *Boule de Neige*, *Mrs. Anthony Waterer*, and *Mrs. John Laing*.]

INDOOR PLANTS.

SUMMER TREATMENT OF CAMELLIAS.

CAMELLIAS as a rule will now be in full growth, and the quicker and more robust they can be made to grow the better, as this will ensure a thorough ripening of the young wood before the short days set in, and be a great advantage to them at the blooming period. Nothing equals well developed, thoroughly matured wood for producing blooms abundantly and of the finest quality.

PRUNING.—In many instances this is necessary. We are often obliged to do it, and in no other way. Some of our trees which are growing in a road house became so close in growth last year that it was impossible to see into them or through them. As soon as they had finished blooming in spring, and just before they had got fairly into growth, we found great armfuls from each of them, so as

CLEANING.—Where the leaves are close and the branches massed together, ordinary syringing may not have kept the foliage quite free from dirt and insects, but as soon as pruning is over a thorough cleansing must take place. The wood may be brushed with a hard hand-brush, and all the dirty leaves carefully sponged. Once thoroughly cleaned in this way, they may easily be kept in that condition by frequent syringings. Plants which may not want pruning should also be cleaned before growth has much advanced. Then comes

ROOT ATTENTION.—Camellias are not benefited by having their roots upset annually; on the contrary, once they get into a thorough growing state they are better undisturbed for years, but they must be well supplied with water. It is of much importance that all the soil about the roots be in a sweet, moist condition before growth begins. Without this their progress will never be satisfactory. Those in pots should be plunged in some material at

and it is seen that the flower-buds are well set, syringing may cease, and water may be more sparingly applied at the roots, at the same time avoid drying them off in any way or withholding water until the roots or leaves shrivel. Plenty of air should also be given them at that period; anything like a close, moist atmosphere and much shade must not be encouraged. Flower buds falling off before they open is a complaint often heard; but this is only the result of some severe check or change in the state of the soil or atmosphere. Immature wood never holds its buds or opens them so freely or well as that which is hard and sun-ripened, and this all should do their utmost to secure from now until well into the autumn.

HEATING CONSERVATORY.

(REPLY TO "HEAT.")

If the conservatory is detached from the dwelling house, it is quite probable that heating by

Flowers of Pansy Pembroke in a glass bowl. From a photograph by G. A. Champton. (See page 206.)

to admit light, air, and sun into them, and those then they have gone on growing in a most satisfactory way. From some of the old shoots there are six and eight growths about a foot in length each, and they all look like bloom-bearing wood. Had they not been pruned they would have been one intricate mass of shoots, with small chance of ripening properly; now their chances are much better. As a rule, it is now too late in the season to prune, but were I beginning to take Camellias in hand which would be benefited by pruning, I would even now be inclined to let daylight into them. This might check them for a little time, but before the end of the season they would be in better blooming condition than if left too thick. The main growths need not be removed, but where there are many small weak branches clustering together many of them may safely be taken off. This is the first thing which should be seen to in beginning the summer culture of the Camellia, and secondly, the

this time, a plunging lessens the chances of their becoming at any time too dry. Soot-water may be given at the roots once weekly with advantage, and from the time the shoots can first be seen until the bloom-buds are visible they should be syringed overhead once or twice daily according to the brightness of the weather. Respecting the

TEMPERATURE in which Camellias should make their growth, there are great differences of opinion, some putting their plants into a viney or Peach-house, but ours are never out of the house in which they bloom, a structure where artificial heat is never introduced except to keep out frost. In some cases much shade is applied, and in others none at all, and under both modes of management the plants succeed, but our experience leads us to prefer no shading. When once subjected to shade, it takes careful treatment to harden them up to stand the sun-heat again, and a little of this is necessary in order to ripen the wood well in autumn. As the growth has been completed,

oil-lamps would do to some extent, for the moment, at least. Of these or, rather, the oil-heated stove, which is a great improvement on the original lamp, quite a number are given in the advertisement columns weekly. Apart from these, which are never so good from the heating point of view as the hot-water apparatus, are some kinds which can be fixed to the outer wall occasionally, and at other times quite independent. Here, however, is an instance of the latter. A gentleman of our acquaintance has a small conservatory fixed to his dwelling and covering the French window entrance—or, rather, where this originally existed—or exit to the lawn. A tiled path and a step-stage are on each side, the lowest stage for plants being at 3 feet from the floor; folding-doors at the garden end, and turning to left and in corner against the house is the boiler-house. It is of wood, 5 feet high at back, 4 feet high at front, 3 feet 6 inches wide, and perhaps 6 feet long. The wood roof is so hinged and in sections that it may be folded

completely back, and with a buttoned door in front opens the whole to view for stoking, etc. The boiler is a small independent one, fed from top, and the shed when closed may be easily mistaken for a nicely-arranged, neat, compact garden tool house. It is not seen from the greenhouse, and what is seen from the garden only reveals good workmanship and an ingenious mind. The entire thing is painted dark brown. The boiler is sunk 2 feet below the level, a depth that admits of the necessary rise around the further side of house, where the pipes cross beneath the window-sill. Three-inch pipes are used, and a temperature of 70 degs. is easily obtained if necessary. The size is rather more than that given of yours. The pipes are connected, so that on entering the house one section turns sharp up the left side of house, while the other extends to the opposite side in the same way. It is possible a modification of the above would suit your own case. If you refer to seedlings of *Canelina* and *Asalea* as well as *Begonia*, we may say at once the two first are extremely slow in growth, even when under expert treatment, but the *Begonias* should make more headway with warmer days. The cold, sunless spring of the present year has not favoured a quick growth in such plants, and if the young seedlings are pricked off singly, you must take care that the soil is not soured by over-watering, or that the sun does not scorch them when dry. The happy medium between the two will be the safest plan. A lung frame is a very suitable place for *Begonias* if the heat be not too severe or the manure too rank.

NOTES AND REPLIES.

Cutting down Ficus.—I have in conservatory a very thriving *Ficus* in an 8-inch pot, with stout stems, total height nearly 12 feet. Half way up are five vigorous shoots, each 4 feet or more in length; two more are forming up higher, and there is growth from every point. The plant is within a couple of lines of overhauling roof. If I cut down the centre stem a certain distance, shall I permanently damage the plant? It has been growing about three years, from quite a small pot plant.—*OSWALD.*

[There will be no risk of permanently damaging your *Ficus* if you cut the stem down to the required height, as it will soon recover therefrom and push out fresh shoots, provided it is done at once, as, by so doing, the plant will have a long growing season before winter sets in.]

Greenhouse climbers.—Do not let the climbers escape notice; if any be getting too crowded in growth some thinning out will certainly be advisable, and at the same time preferable also to tying in closely. This latter plan is senseless to a degree: it gives a trimmed and prim appearance, it is true, which some may think the right thing to adopt, but it is neither conducive to flowering nor to the health of the plants. Where climbers are turned out do not let them escape notice in watering; most of these will now take a liberal supply.

Arranging plants.—Overcrowding is an evil to be guarded against. There is a temptation frequently to use more plants than would otherwise be the case simply because they happen to be in flower. This often occurs through want of management in regulating the supply, which is easily done by a little tact. Take *Pelargonium* as an instance of overcrowding. These, when stood closely together, will soon have a number of leaves turning yellow, whilst at the same time it fosters an attack of aphid, the two combined tending to shorten the flowering period. Rather than allow overcrowding, it is decidedly better to grow fewer plants and thereby have them at the same time more presentable.

Fuchsias.—Up to this time it will have been found an advantage to continue stopping the stock of *Fuchsias*. Now those intended for the earliest bloom should be allowed to grow away for flower; this batch will then come in useful early in July, just when in many cases there is a lack of bloom. Others should be allowed three weeks longer before another stopping, and younger plants another one still. This is far better than permitting them to rush into flower all at once. The later stock will be all the better for another shift if they have not had the second since the spring shaking out and repotting. This will not be possible in the case of basket plants or those probably that are trained up the rafters; these, therefore, should

receive liberal treatment instead. Any other plants seen to be coming on more speedily than is desirable should also be stopped, or at least have the flowers picked off in an early stage, so as not to weaken them for later use.

Cineraria stellata. In this, the individual flowers, much smaller than in the ordinary florist's *Cinerarias*, are borne on long, branching heads in great variety of colour, and, when in bloom, might be mistaken for Michaelmas Daisies. Very large plants may be grown in 6-inch or 7-inch pots, and, where conservatories have to be kept gay with a mixed collection of flowering plants, a few well-grown specimens will be found invaluable. They need plenty of moisture and careful shading from strong sunlight, when they give a long succession of bloom, as the main stems branch out very much more than in the ordinary varieties. It is unfortunate that *Cinerarias* are so liable to green-fly. I find, however, that when they are kept in quite cool quarters no fly will touch them, and for several winters past I have kept all my stock in cold-pits or frames, and relied solely on covering with mats and litter to keep the frost out, only removing the plants to heated houses when the flowers were nearly ready to expand. This plan entails a good deal of work in the shape of covering and uncovering, but it pays in the end.—*JAMES GRIMM, Wootton.*

Cytisus.—By now most of these will have passed out of flower, and require cutting hard back to within a couple of inches to where last pruned, keeping a bit drier at the root for a week or so, but syringing overhead two or three times a day until new growth starts afresh. A cold-pit or frame, if closed towards 4 p.m., after dewing overhead, will be a suitable place. Before growth has much advanced reduce the ball of soil a bit, and repot into a trifle larger pot, potting firmly, and standing back in the same place for a few weeks, when remove outdoors to a fairly sunny spot. I like to use a little peat with the loam, and just enough sand to keep all sweet and porous, as the plant soon succumbs if treated roughly or regards over-watering or an injudicious use of manure of any kind. Pinch out the points of the strongest shoots if taking the lead, though this should not be practised late in the season or the growths will not get ripened and fail to flower satisfactorily. Many gardeners fail to root cuttings of this plant, and they certainly are a bit fickle, but I find little difficulty about this if taken when 3 inches long with a bit of old wood, and dibbled into a shady nook in the conservatory. They take longer here probably to form roots, but few go off, and by autumn they may be lifted and potted up, making nice lushy plants by the following autumn in 5-inch or 6-inch pots. I have also raised a stock from seed, but the plants are much more straggling and require to be pinched several times to keep the base well feathered. Cool treatment suits this plant best at all seasons.—*J. M. B.*

Caladiums. As summer and autumn line-foliage plants these stand in the foremost rank. Of late years they have become popular, and rightly so, seeing the diversity of colour in the leaves. They may be grown small enough for a small vase, or into big specimens many feet through. Everyone who has visited the Temple Show in May or early June must have been attracted by the glorious groups put up there. Everyone who grows these for decoration should not select the very tall-growing kinds as these are totally unfit for this use. Nothing can be more beautiful than a well-grown plant of *C. argyreatum* for placing on the dinner-table. Its small, dwarf habit, with pure white and green leafage, is most striking, especially when well grown and the foliage hanging over the pot. All of the highly-coloured leaved kinds are liable to get scorched with the sun if grown where it can shine direct on them, but they are safe when under a thin shading. *Caladiums* may be grown in a warm-pit in the summer, and may be started in a Cucumber-pit. The bulbs may be wintered in any place where the temperature does not drop lower than 50 degs. to 55 degs. If they are needed for conservatory embellishment, then they should be brought on slowly, giving an abundance of air. I have seen them stand in cold-houses in autumn when grown in this way.—*J. CROOK.*

FERNS.

A USEFUL LITTLE FERNERY.

SOME years ago, on adding a range of cool niches to one of our heating systems, the connecting flow and return pipes had to traverse a considerable distance out-of-doors, and rather than bury these pipes, they were carried along the north front of the back wall of a late-vinery, and their heat utilised by excavating the ground 3 feet deep and building a small sun-house 6½ feet wide over a portion of them. This is in the form of a lean-to, the roof appearing as a continuation of the back part of the hip-roofed vinery, with the bottom of the sashes resting on the plate on a low brick wall in front. This little house or pit we last spring converted into a place for Ferns to supply cuttings. These are at all times in request, and who can wonder at it, seeing that most flowers in a cut state are so much improved by association with them. In our instance so valuable have they become that it was imperative to provide for a regular supply of them in some way; numbers of different kinds are grown in pots, but mostly for conservatory decoration, and one cuts plants in pots with reluctance. We have no pots in this fernery, everything being planted out; attention in the way of watering is thus greatly lessened, and the health of the plants is increased. The door being at the west corner, next the high wall, the body of the house is formed into one raised bed, sloping up to the front wall, in which the Ferns are planted; 24 feet are allowed for a path straight along the side of the back wall, and the bed is enclosed by a 4½-inch brick wall seven courses high; drainage has been thoroughly provided for, and a good lasting mixture of peat and leaf-soil, with sand liberally added, was used for the bed, which is firmly filled. At the time of planting, cuttings of *Ficus repens* were thickly dibbled in along the foot of the low rear wall in front; most of them rooted and now prettily clothe the wall up to the woodwork. Four wires are fixed lengthways along the roof, on which are trained *Lydinium scandens*, *Cissus discolor*, and *Selaginella casaria arborea*. On the back wall are three rows of spouting, such as builders employ under the eaves of houses to catch rain-water; these are fixed one above the other 18 inches apart; their widths are 4 inches, 5 inches, and 6 inches; the widest one is at the bottom. Small holes were drilled 10 inches apart in the bottoms of these troughs to enable the superfluous water to escape, and after being well filled with soil, laid on a layer of pounded charcoal, they were thickly planted with the following, all mixed together, viz.: Ferns of various kinds, consisting of the smaller growers, *Selaginella Kraussiana* and its golden variety, *apoda*, *involvens*, *Martensii*, and *M. albo-variegata*; also *Begonia of the Rex type*; *Pellionia Dauveana*, *Pannaria variegata*, *Tradescantia zebrina*, *aurata*, and multicolor, and the red and white veined *Fittonias*, all of which grow in them as well as could be wished. We much prefer these metal troughs in earthenware ones for such a purpose as this, because they are practically imperishable; the plants in them do not need a tithe of the attention as regards watering that they do in more porous material, and they thrive equally well, if not better, in them than in earthenware. It is a simple, quick, permanent, and effective way of draping with vegetation high walls in warm plant-houses. The varieties of Ferns which we have are mostly such sorts of Maiden-hair and *Pteris* as we found most durable and least liable to be injured by cutting. Few are more useful than *Adiantum cuneatum* and *Pteris serrulata*. A great advantage in having Ferns for cutting by themselves is that we can ventilate freely, and by comparatively cool treatment render the fronds doubly durable. Immersion in water for a short time before packing them also greatly helps to keep them fresh. A. C.

Management of Fern-case.—I shall be much obliged if you will give me in your paper any advice as to the management of a Fern-case. I have a glass case, 25 inches long by 17 inches wide, which opens by doors at either end; a little ventilation is provided at both top and sides. The case stands in the window of an unheated room. I have tried *Filix Ferns* and other hardier kinds, such as *Adiantum formosum*, *Doodia caudata*, etc., but none do well. In most cases the foliage soon turns black.

and the Ferns die, or, if they live, they lose their freshness, and any new fronds are small and poor. I do not water them overhead, and at the roots only when the soil appears to be dry. I sometimes give ventilation by opening one of the doors. There is not much depth of soil in the case, but plenty of crocks, etc., for drainage. I shall be much obliged if you can give me any likely cause of failure.—D. C. M.

[The floor of your Fern case should be a flat zinc trough, with a small outlet pipe to carry off surplus moisture. This should be partially filled with rubble, and on it be laid some pieces of tufa stone, making in this way small pockets to hold soil in which Ferns and Mosses may be planted. The best compost is turfy loam, peat, and sand, with which should be mixed some pieces of charcoal. Use such Ferns as *Pteris cretica*, *Adiantum capillus-Veneris*, *Asplenium Trichomanes*, and *Davallia bullata*, carpeting them with *Selaginella Kraussiana*, or any of the hardier Mosses. Keep the plants free from decaying fronds and wash the glass occasionally. Plants growing in such a case will not require much water, as the evaporation condenses on the glass and runs down to the roots again. A little ventilation is sometimes beneficial in the morning.]

FRUIT.

PEACH-TREES CASTING THEIR FRUIT.

There are four fruits of Royal George Peach. Can you tell me the cause of their falling off; in fact, the whole crop has fallen? Also I have three more trees in the same back. Two are dropping their fruit as the above, but the other one seems more satisfactory. The trees are fairly healthy. The Royal George is an old tree, but the two others are young ones.—S. J. A.

[Your Peach-trees are casting their fruit from one of the two following causes: (1) Allowing the trees to carry far too great a number of fruits up to the stoning period, when the strain becomes so great that they are unable to perfect the kernels in the stones, with the result that the fruits drop in the manner you describe. (2) The absence of lime in the soil composing the border. Peach trees both demand and assimilate a great quantity of lime to enable them to perfect their seeds or, in other words, the stones and kernels, and when this constituent is absent, or present in but small quantities, they cast their fruits at the critical period designated "stoning." This brief explanation will enable you to arrive at a conclusion as to which of the two causes named your trees are suffering from. If it is the first mentioned—although nothing can be done this season—you should be on the alert and thin the fruits down within reasonable limits should a heavy set result next year. Many cultivators thin out, so that when the fruits have perfected their stones there are but a few dozens to pull off. A safe rule is to have about double the number that will be ultimately required. A good and safe crop should never exceed one fruit to every square foot of trellising clothed by the branches of the trees. If, on the other hand, you arrive at the conclusion your trees are needing lime, you can supply their needs to a certain extent now by dressing the border with the following mixture: Take 1 lb. muriate of potash, 2 lb. superphosphate of lime, and 2 lb. of bonemeal. Mix altogether, and then dress the surface of the border with it at the rate of 2 oz. to each square yard of surface, and lightly prick it in with a fork. Then well water it in, and in from six weeks' to two months' time give the border another dressing, but only half the quantity on this occasion, and water in as before. When autumn arrives, or a week or so before the trees cast their leaves, we would advise you to lift your trees and remake the border, wholly or in part, taking great care to use, if possible, a sound, calcareous loam as the chief constituent. If this is not to hand, you must supply the deficiency in the loam you use by mixing a fair quantity of old mortar-rubble, such as plaster or old mortar saved from buildings in course of being dismantled, also 4-inch bones at the rate of 1 cwt. to each ton of compost, and bone-meal in the same proportion. Make the new border as firm as possible by well treading the soil as it is wheeled in, even going to the length of ramming it, if it should be at all dry. A firm, compact border will ensure medium, short-jointed, fruitful wood being produced, and trees growing in such a compost never fail to set and perfect their crops. Should you require further information

as to how to lift the trees and correct formulae as to the making of a Peach border, please address us again and we shall be glad to assist you.]

NEWLY-PLANTED VINES.

There is a great difference in the way in which newly-planted Vines are treated by different growers. Instead of cutting them back to the wall plate, some leave them nearly the whole length with the view to getting the rods up to the top of the rafter as quickly as possible, and by this means save time. Than this there cannot be a greater mistake, unless conditions are exceptionally favourable, and more than ordinary skill and care are brought to bear on their after management, so as to ensure every bud breaking from top to bottom of the canes. As we generally see them, a few buds near the top are all that start, all below being a blank, which after all necessitates the Vine being cut back to ensure fruiting spurs from the bottom upwards. Therefore, it would have been better to have cut them down first, and thus prevented loss of time. Even when all the buds start into growth, when the canes are left their whole length, two or three buds at the top will, if not properly managed, monopolise so much of the strength of the rods as to leave shoots below them in a very weak condition. When due care and patience are exercised it is possible to get every bud on a 6-foot-long cane to start into growth, but the cane must be carefully bent down so as to insure the bottom buds breaking first, and the tops must not have a much higher temperature than the roots, or the buds will be sure to break weakly. This is the rock on which many inexperienced people wreck their hopes of a satisfactory start. They plant perhaps in February or March, and as there are no Vines on the roof to shut out the light, the vinery is turned into a forcing-house; the consequence of this is the tops of the newly-planted Vines are forced while their roots are in a cold border outside. The tops, therefore, grow away for a week or two until they have consumed all stored-up nutriment. They then come to a standstill, and only recommence to grow again when the outside temperature has risen sufficiently to make the roots active. There is no reason whatever why a vinery should remain empty just to accommodate the Vines, but if the border is outside, and they are planted in March, the tops should be temporarily nailed to the wall outside. At the end of April they could be brought inside, as by that time there would not be so much difference between inside and outside temperatures, and by the time the tops had started into growth the roots would also be active, and a proper balance between tops and roots would be maintained. In a general way it is inadvisable to cut down newly-planted Vines, and when it is decided in autumn to plant Vines in spring, plants for that purpose should be obtained and immediately cut back, leaving only 2 feet of cane, so that the wound might have time to heal before growth commenced in the spring. C. C.

GRAPES FOR EXHIBITION.

I should be much obliged if you could tell me the best way to grow Grapes for exhibition in September? They are Black Hamburg, and are only just setting now. They are grown in a lean-to vinery heated with hot water, and are planted inside. The roots are able to grow out as well. I can get plenty of liquid manure, also superphosphate.—S. J.

[The particulars furnished in your letter are very vague when seeking such advice. The age of the Vines, extent and nature of border, would have afforded useful and important data. However, we may tell you that to get well-finished Black Hamburgs, good enough for exhibition, demands a great deal of careful thought in the daily routine. The soil ought to be of the best description and the border properly drained. A great many readers would be only too pleased to obtain exactly the same information you seek, but local circumstances vary so much that no uniform practice suffices for all. Water is a most important item in Vine growing, and the frequency necessary for its application to the roots depends entirely on its elevation, the nature of the soil, and the house. We know of a vinery that is given water twice or not more than three times a year, with the result of other instances where it is

made a rule to give water every day in summer, but the two instances are so extreme that a combination of the practices would certainly not result in show Grapes, yet these two gardeners were each successful exhibitors. A heavy soil will not need half the water a light one would; we know of outside borders that never get any moisture except that afforded by rain. Your inside border may need water once a fortnight, or it may be once a month, much depending on soil and situation. You must examine it frequently to ascertain the extent of moisture, remembering that Vines when in full growth absorb a deal of water from the soil. Manure-water will be beneficial given in a diluted state at each summer watering, provided your Vines are in full bearing and the border well occupied with healthy roots. Much depends on this. An excess will poison the soil and ruin your prospect of success. Superphosphate is not a manure suited to Vines by itself; something is needed in conjunction, but your liquid manure, if obtained from a mixed source—pigs, cows, and horses—would do that. Bone-meal is good for Vines, and a little sulphate of ammonia used with superphosphate is good for some soils. Ventilation is another important point, and on this largely depends a good colour in the berries. When Grapes are ripening never close the roof ventilators down quite close, but allow air to escape, for a buoyant atmosphere is favourable in a dense bloom. If the air is overcharged with moisture and the ventilators kept closed too much, the berries assume a shiny, polished appearance instead of showing a hoar-like bloom. The berries when set need to be thinned in such a manner that they have space to swell to full size without becoming too closely compressed together. This is a bad practice, and can be carried on over a few weeks if it is found that the first effort does not satisfy. Keep all superfluous lateral growth suppressed, so that the principal leaves have an exposure to light and air. It is well to go over the Vines every week and pinch the shoots until their growth is such that it does not call for it. To get the best results we would advise a little Vine-manure once or twice during the season, as this does the border good, sprinkling it on the surface and watering in.]

Thinning Peaches.—I have Peach-trees under glass. The fruit is now about the size of large Bantons, in many cases in clusters of three or four. Is now about the right time to thin them, and ought more than one to be left on the cluster? What distance ought they be from each other on the branches? I should also like to get information on the same points with regard to Apples and Pear-trees now in full bloom.—CARD.

[It is quite time your Peaches were thinned, although it is not always a good plan to commence this too early, simply because the fruits will occasionally swell to the size you name, and then become stationary. When, however, they set so thickly on the trees, a moderate reduction should be made as soon as they are set and swelling, continuing this periodically. By doing it in this way the work is simplified, because it is more easy to define the better fruits from the lead they always take. If we tell you that one fruit to each square foot of tree surface is considered sufficient for a crop, you will the more readily understand the extent of thinning necessary. Certainly two fruits ought not to be left together on one branch. From 9 inches to a foot apart will give you the desired crop, if this is uniform over the whole tree. Apples and Pears when thickly set repay as much as Peaches to be thinned, leaving not more than one fruit where a cluster has set. If more of this could be done there would be fewer complaints about tight and heavy crops alternating from year to year. With a heavy crop the resources of trees become overtaxed, and the result is found in the barrenness of the succeeding summer as affecting such trees. If you reduced all the smaller-growing Apples and Pears to one on each twig, larger fruiting sorts even more severely, you would get more typical fruits and regular crops.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER-GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, and which will be marked thus:—

GARDEN WORK.

Conservatory.—By growing a suitable collection of Lilies one may always have a few in bloom, and Lilies are now very much in the ascendant for decoration. The most lovely of all, to my mind, for pot work is *L. longiflorum*, and by adopting cool storage the season is practically continuous. But I am not sure that we want anything, not even Lilies, continuously, not even *longiflorum*. We generally begin with *Harrisi*, but of late years this Lily from Bermuda has been much diseased, and many failures have occurred in consequence. Next to *Harrisi* comes the *longiflorum* from Japan, but this last season there have been symptoms of disease in the Japanese bulbs, due probably to forcing culture and a desire to be first in the market with large bulbs; at any rate, there is disease in some of the bulbs, but the sound bulbs have thrown very fine spikes. The *lancofolium* section is one of the most useful to the gardener. The bulbs live with him without deterioration, and by placing a number of bulbs in a pot very fine specimens are obtained that will last some time in a cool conservatory, and all conservatories ought to be kept as cool as possible now. Very many Lilies not usually grown in pots will do well in this way. The double form of the Tiger Lily does very well in pots, and a good specimen standing among *Feruss* and *Eulalias* has a pretty effect. A house full of the usual kind of plants—*Begonias*, *Geraniums*, etc.—may be bright enough, but does not altogether satisfy. We want something else, and this is where a good collection of Lilies to draw upon comes in so useful, and now the weather is warmer we can move some plants from the warmer houses. *Eucharis* Lilies, coloured-leaved *Dracenas*, and various other things can be moved to the conservatory for a few days at a time to cause those pleasant little changes which people of taste so much appreciate. The coal-ash-beds should soon be in readiness for turning things out to ripen. Zonal *Geraniums* for winter flowering, of which the most valuable for cutting are *Raspail Improved* and *Mme. Rozain*, should be shifted on when required; at present these will be in a cold-frame with the lights off, except during heavy rains. No plant requires more careful watering than the Zonal *Geranium*. If the soil gets sour the plant may be thrown out.

Stove.—The value of a low, close pit to relieve the stove of the young stuff will be very great just now. Young growing specimens must have room, and for the time being almost any structure may be made to grow the majority of stove plants and Ferns. We generally move all the young growing stock of *Feruss* into a cold-pit with a rather flat roof, and whiten the glass, giving only ventilation sufficient to harden the fronds. Here they are quite at home, and of a splendid dark green colour, and the attention required is nothing like so much as is necessary in a house which gets warm from the sunshine. The training of climbing plants on balloon or other shaped trainers must have timely attention. *Allamandas*, *Bougainvilleas*, *Clerodendrons*, and *Diplolenias* are among the brightest summer-flowering stove plants, and the training of the young shoots up into the light is important, fit-and-by, when the flower-buds are visible, the shoots can be trained to the best advantage. Fires must be kept in check in bright weather. If the pipes are hot in the daytime when the sun is shining frequently, the fuel is not only wasted, but the dry atmosphere is injurious to the plants. Sixty-five degs. at night is high enough. If the thermometer inside will stand at 60 degs. in the morning we shall let the fires go out.

The stoning period in fruit.—This is a critical time and must not be hurried, or the fruits may fall. The temperature should be kept steady and the roots moist. When the stoning of Grapes, Peaches, and Plums is finished, nourishment may be freely given. If there is a farmyard-tank handy that will suffice. In the old days we relied on the manure-tank entirely, and the results were satisfactory. Feeding with artificial manures takes less time but requires more judgment. I have seen remarkable results from using

Peruvian guano freely one season, but the next the results from the same quantity were not equal. This shows that the use of any kind of manure may be overdone, and that to manure properly a mixture of substances is necessary. Our usual course is to use potash and phosphatic manures early in the season, and give the finishing touches with guano or nitrates when the stoning is completed. Whatever artificial manure is used should be carried in by watering at once, and not left on the surface.

Potting Chrysanthemums.—This is the season for shifting into the flowering pot. Many growers have probably got forward with the work of the general collection, but the culture of this beautiful autumn flower has been so extended that it has branched off into many directions, and the plants are grown in various ways for different purposes. Cuttings of the strong leads, struck now without flagging, will throw good flowers in 6-inch pots, and are very useful for grouping for exhibition. All the plants must now be in the flowering pots, and a regular system of training, insect watching, and other routine work in connection therewith must be gone through. The fungus known as rust has not shown itself with us yet. This, like many other diseases, is brought on the weaker of the plants by a rushing system of propagating and culture, and will disappear under rational treatment if one could get clean plants to start with. Of one thing I am convinced: though the *Chrysanthemum* will do fairly well amid the smoke of the town, it will do better in the pure air of the country, and, if one grows stock for sale, the country is the place to grow the stock plants. Firm potting is necessary for *Chrysanthemums*. We always leave space on the top for a top-dressing later, as we find the plants like this. It is better even than too much liquid-manure, which may clog up the soil.

Window gardening.—What a rush there appears to be for red, white, and blue flowers this season. It is difficult to provide novelty at a moment's notice, but white Lothian Stocks might take the place of the white *Marguerites*, which, unless grown very cool and sturdy, get too tall. The Lothian Stocks are sown in autumn generally, though we have sown in spring, and grown on near the glass in single pots till transferred to the boxes. The best scarlet *Geranium* for boxes is *West Brighton Gem*. *Improved Raspail* and *Improved Vesuvius* are much in demand for brightening up gardens this season. The *Crimson Jacoby* also is in request.

Outdoor garden.—Just now the Thorns, Laburnums, and Lilacs are lovely in suburban and other gardens. To form good heads with long, drooping branches the young Thorns should be pruned back for a year or two till a good base has been secured, and then let them grow as they please. Laburnums and Almonds may be treated in a similar way. Lilacs and flowering shrubs generally should have what pruning is required as soon as the flowers fade. All tender plants used in the various forms of garden decoration may be planted now. The carpet beds, if any of these expensive features remain, will come in after the late Tulips or other late spring flowers, but special care should be given to the preparation of the beds. There is nothing equal as a top-dressing to the charred garden refuse which is obtained from the prunings and clearings of the garden. The sowing of Wallflowers and other hardy perennials and biennials must not be delayed any longer, or the plants will be weak and poor. Put stakes to all plants likely to require support early. Every kind of garden Pink should be grown, for there is a charm in variety in these fragrant flowers. The old florists' or lace Pinks are very sweet and beautiful. There are many beautiful things in flower in the rock-garden now that will attract attention.

Fruit garden.—The frosts have not done much harm so far as can be seen in our district. There will be plenty of most kinds of fruit if they stop on, or only a reasonable proportion remains, and the recent heavy rains have had a beneficial effect. There are a few curled leaves on Plums and blistered leaves on Peaches, but the energetic cultivator will know

how to deal with insects. Certainly there is a better promise of fruit than might have been expected, considering the character of the weather during the greater part of the month of May. The thinning of the young wood and the fruits on wall-trees must have attention. This refers more especially to Peaches and Apricots. The time for summer pruning of Peas and Apples is not yet. July is time enough for the consideration of that work. Of late years there has been a tendency to put off the summer pruning till the end of August or even later, but that has been found to be a mistake, and most cultivators are now regarding this necessary work in a reasonable spirit. Some kind of mulch to wall-trees seems a necessity. It need not be anything of a stimulating nature, but it should have the effect of keeping the moisture in the soil as a check upon deep rooting. A loose, freely-loosed surface will be better than nothing, but stone fruits do best in a firm soil, so the soil-stirring should be confined to the surface. The digging of fruit-tree borders should be given up if the roots are to remain near the surface.

Vegetable garden.—Sow Spinach of the round-leaved kinds on cool borders. The north borders come in useful now for Lettuces, Cauliflowers, Turnips, and Spinach. But the New Zealand Spinach must have the sunniest spot available. The practice of planting greens among Potatoes can only be recommended where land is scarce, but in some places it must be done among the early Potatoes. It does less harm when every alternate row of Potatoes is missed, as then the tops of the Potatoes can easily be turned aside and the greens given a chance. On the same principle, if economy in cropping the land is necessary, the double row or the bed system can be adopted where much Celery must be grown. Growing two rows of Celery in one trench is a common method of culture and answers very well, and the bed system, which is merely an extension of the double row system, enables the cultivator to turn out a lot of useful Celery for cooking from a small plot of land. Never use rank manure for Celery, and blend it well with the soil in the bottom of the trench. Keep the Tomatoes both indoors and outside free from side shoots, but leave all leaves entire as long as possible. It may be necessary when fruits are colouring to reduce foliage, but the fruits from plants which have been robbed of foliage are always poor in flavour. Mulch Vegetable Marrows and ridge Cucumbers with littery manure, and peg out the shoots to prevent shifting by the wind. Give liquid manure to Globe Artichokes to produce succulent heads. Thin all young crops of vegetables in good time, and keep the hoe going. E. HOUST.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 16th.—Planted more Canadian Wonder French Beans. We give these plenty of room, and all pods are gathered from Beans and Peas of all kinds as soon as fit for use. All Peas are mulched with littery manure on both sides of the rows; this is a great help in a dry season. Planted more Autumn Giant Cauliflowers; this and Veitch's Self-protecting Autumn Broccoli are very reliable. Finished planting sub-tropical plants; plants have been well hardened.

June 17th.—Put in a batch of cuttings of late-flowering *Chrysanthemums*; they will be rooted in a close frame. Strong leading shoots have been selected as cuttings. We find these plants useful for grouping; each plant will carry one good-sized flower. We have been thinning stone fruits on walls; many trees are too heavily laden. Covetousness brings its own punishment in weakened trees, which are more subject to insect attacks. We are using Tobacco-powder freely wherever insects are likely to appear or are appearing.

June 18th.—We are growing Asparagus on the French or row system, and are so satisfied with the result that we shall make no more beds. We cut all grass as it appears. The small stuff does for flavouring soups, and in about another week from this date cutting will

cess for this season, and all spare liquid from the manure-tank will be given to the plants, possibly supplemented with guano or some artificial.

June 10th.—Pegged down *Verbenas*, *Heliotropes*, *Ageratum*s, and *Potunias*. We like to do this before the stems get much into growth, as they are more pliable. Planted out more celery and sowed more Marrow Peas. This will be the last sowing of late Marrows. Outdoor Tomatoes in the open have been staked. When three bunches of fruit have been secured the leaders will be stopped, to concentrate growing force, as late fruits seldom ripen.

June 11th.—Rearranged conservatory and introduced some of the hardiest plants from the stove. A few of the large Palms have been plunged in sheltered spots outside in the grounds. India-rubbers and *Grevilleas* have been utilised in sub-tropical beds. Climbers in the conservatory are now a special feature. Oranges in pots and tubs have been placed outside on terrace. Zonal *Geraniums*, *Begonias*, and *Malmaison Carnations* are good features.

June 21st.—Now that the houses have been partially cleared attention is given to the young stuff in preparation for winter decoration. Among other things, a lot of *Club Mosses* are grown in pots and pans. The pretty little *Madeira Grass* (*Isoplepis gracilis*) is also useful. Seedling Ferns and young Ferns generally are grown in cold-frames, shaded. We find rather that frames do best for this work, as also for *Cyclamens* and *Primulas*. Earthed up *Potatoes* as they advance in growth.

BIRDS.

The Redpoll (*F. N.*).—This is a native of the northern parts of England. The nest is usually built on some low tree or dense bush, and is composed of Moss and dry Grasses, intermixed with the down from the catkins of the Willow. The docility and confidence of this little bird render it very pleasing as a feathered pet, although it has no natural song beyond a few sweet, twittering notes. Various seeds constitute the food of the Redpoll when at liberty. In captivity it may be fed on Canary-seed, Rape-seed, broken grits, with plenty of green food, and now and then a few grains of Hemp-seed.

Death of Canary (*G. R. Creswell*).—In this case death appears to have been due to inflammation of and internal hemorrhage from the lungs. The bird must have taken a severe chill, probably from exposure to a current of cold air. The sample of seed was very good—the best of its kind, so there was no fault in the feeding. The "fresh common sand" would not, however, be of much good for assisting the gizzard in the digestion of the food. Sharp grit is the proper thing to supply for this purpose, and without which no seed-eating bird can remain long in good health.—S. S. G.

—(*Alice Wethered*).—Yes; no doubt this bird has been partaking too freely of the egg-food supplied for the nesting hens. This kind of thing often happens during the breeding season. Only a little egg food should be given two or three times a week and discontinued after the birds have paired until the young ones are hatched. When there are young to feed the old birds are not so liable to take an undue allowance for themselves.—S. S. G.

POULTRY.

Death of chickens (*A. C.*).—You do not appear to be feeding your chickens judiciously. A diet of "boiled rice, mashed Potatoes, Cabbage," and so forth is not sufficiently nourishing, and the long spell of cold weather rendered it necessary to feed highly. They should have a thick, crumbly paste made of two parts of coarse Oatmeal and one part of Barley-meal, mixed with milk or water. Grits, crushed Wheat, or bruised Oats should form the last meal at night. In a cold hatching season chickens should have for the first three or four days hard-boiled egg minced small, also a little finely shredded underdone meat till they are about three weeks old. This stimulating diet should be given regularly, and when

chickens suffer from bad feathering, caused by the coldness of the season or from delicacy of constitution, bread soaked in ale is often given by poultry rearers. Aute' eggs are very good for young chickens early in the season before insects become plentiful.—S. S. G.

Death of hen (*Hen*).—You send no particulars whatever as to feeding and general treatment. The bird was exceedingly fat, and the liver was diseased. You appear to be supplying food to your fowls of too rich and stimulating a nature. Many deaths are brought about in the poultry yard through overfeeding or the use of unsuitable food. The free use of Maize is sure to lead to the formation of internal fat, and, as this accumulates, egg production ceases, and the hens fall a victim to disease. Let the diet of your hens be of the plainest and restricted in quantity for a time, otherwise you will probably sustain further losses. If any of your other hens show symptoms of liver complaint, which are a moping about, an irregular appetite, and a yellowish tinge on the face and wattles, give per bird every other day for a week or so one grain of calomel, mixed with the soft food, which should be given in a crumbly state. Supply plenty of fresh vegetables, and add some sulphate of iron to the drinking water after the course of medicine has been gone through. Give no more food at a time than will be eaten readily, and frequently make a change in the diet.—S. S. G.

LAW AND CUSTOM.

A gardener's testimonials.—Two months ago I took a situation as gardener. If I leave at the end of three months can I compel my employer to give me my characters, or how long has he the right to retain these? In one of his letters he stated that he would pay the cost of removing my goods to his place. Can he refuse to do this?—*Jack*.

—My last employer received references direct (that is, through the post) from previous employers. Can I claim these on leaving as my own property?—*O. F.*

[I suppose by your "characters" you mean certain written testimonials as to character given to you by your previous employers. If this be so, you could have demanded these from him as soon as he had engaged you, supposing that these testimonials had been given to yourself and had not been sent by the givers to your present employer. If these were given by them to him direct, they are not your property; but if given to you and handed by you to your employer, they are your property, and you may sue for them at once, whether you leave or stay. It is a foolish thing to send away or give away the actual testimonials; copies only should be sent or handed in, the originals only when specially required. If you have preserved the letter or can prove the undertaking to pay the cost of removal of your goods, you may sue your employer for such cost if he refuses to pay it. The action must be brought in the county court.—*K. C. T.*]

A nurseryman's notice.—In December last the tenant of a nursery ground engaged me to work for him upon a verbal agreement that a month's notice should be given by either party desiring to determine the engagement. The landlord is at present finding the tenant with money to pay wages, etc., and last Sunday morning some words passed between the landlord and myself, and he told me to take a week's wages and be gone. I declined, and told him he was not my employer, and he replied that if I remained on the place he would advance no more money, and my employer then said he should be unable to pay me. I then asked for a month's wages in lieu of a month's notice, but this was refused, and a week's wages was tendered in lieu of notice, so I took it and went. The landlord never paid me previously, and this transaction took place on a Sunday. Does it stand good, or can I recover the other three weeks' wages?—*J. G.*

[The verbal contract for a month's wages was hiding, and so you could have refused the week's wages tendered and have sued your employer (not the landlord) for breach of contract, and you could have claimed a month's wages in lieu of notice. And you might do this even yet, if it were clear that you did not accept the week's wages as sufficient compensation for the want of proper notice. Your proper course was to have refused to accept the week's wages, and then if you were ordered off you should have brought your action. On the facts stated, it seems to me that you accepted the week's wages, and so the matter is at an end. The fact that the disturbance and payment took place on a Sunday does not affect the legal aspect of the question.—*K. C. T.*]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Diosma ericoides (*A. E. Paton*).—The specimen sent is *Diosma ericoides*, a member of the *Rue* family, hence its very pronounced smell. It is a native of South Africa. Whether worth growing depends in your case upon yourself, for, though to a certain extent interesting, its ornamental features do not rank high.

Planting Rose (*J. J. Butterworth*).—Most nurserymen keep some climbing Roses, such as this, in pots, and, if so, you may obtain your Rose and plant at once, but if the specimen is growing in the open ground, and you desire to transplant it, you must wait till the autumn before carrying out this operation.

Tropaeolum Townsendii (*Helen Evans*).—Numerous inquiries have failed to trace any recent information concerning the *Tropaeolum* inquired about, while a search through various catalogues has resulted in the same way. It is more than probable that it has now completely died out, a fate that falls to the lot of many soft-wooded plants in a few years.

Clematis drooping (*Mrs. Annie Dyke*).—We should imagine your plant has been allowed to get dry at the roots, and, when this happens, no amount of watering will bring it back to a healthy condition. Unfortunately, too, Clematises that are grafted often suddenly die off, this by some being attributed to disease, doubtless brought about by the pernicious forcing adopted in their infancy. We should advise you to cut your plant down to the ground, and then, if the roots are all right, strong growths will break away from the bottom.

Climbers (*J. T.*).—The things most likely to suit you are *Colwa scandens*, *Lophospermum scandens*, or *Ivy-leaved Pelargonium*. Apart from these are the climbing *Nasturtium* and some Clematises or the Hop plant. It is more than likely that the *Ivy-leaved Pelargonium* would prove the most serviceable, inasmuch as by sinking the pots at the base of pillar the plants could be removed for the winter. If a hardy climber would suit you, then we suggest *Clematis Jackmannii*. For the window-box you should get *Campanula Mayli* (blue) or *C. isophylla alba* (white).

Plants for border (*Beginner*).—There are many things you may plant now, such as *Zionias*, *Phlox Drummondii*, *Verbenas*, *Tuberous Begonias*, white and yellow *Marguerites*, or any of the annual *Asters*, etc. You could also get a good display by planting such early-flowering *Chrysanthemums* as white and yellow *Deegantines*, *Lyon*, *Fiercy's Seedling*, *Marie Masse*, *Crimson Queen*, *Ivy Star*, *Quintus*, and *White Quintus*. To a collection of the latter could be added the Sweet-scented *Tobacco* (*Nicotiana affinis*) and some *Gladiolus* in mixture. *Mignonette*, too, is ever welcome when in flower.

Marshall Niel Rose (*J. G. T.*).—If the Rose is in the tub, and this can be moved bodily, the roots that may have got outside will not materially affect its future prosperity. If the plant, tub and all, can be removed, it will be quite safe in a sheltered place in the open, shortening back any of the longer shoots. If the tub will not permit of removal bodily with safety, you may almost ensure this by passing strong mats or sacks around and under the tub, and lacing all up tightly over the top of tub remove it in this way. A strong rope or wire round the tub would greatly help to keep it in position. Otherwise, if the tub comes to pieces, your plant may be sacrificed unless its removal be deferred for a time. We think, however, in the way suggested and by half pruning the Rose the work of removal may be done at once.

Oblong bed (*Beginner*).—A bed 7 feet by 2 feet certainly may be made gay at intervals, but not continuously, from March to November. Plants for March and April would include such *Trumpet Daffodilla princeps*, *Golden Spur*, *Emperor*, *Horsfield*, and the bed may be margined with *Narcissus nilour* and *Anemone apennina*. In May *Narcissus poeticus*, planted alternately with the trumpet sorts at 15 inches from margin, would come in, the other plants named to be in the margin proper. In June you may have a good show with single *Pyrethroms*, while for late June flowering *Delphiniums*. Amid these you may have *Gladiolus*, *Hyacinthus caudatus*, and *Lilium speciosum*, which with *Galliardias* and one or two select *Michaelmas Daisies* would give you some autumn bloom. By planting the bulbous things rather more deeply than usual some other things not deep rooting or with great tufts of leaves could be used.

Hybrid Teas for pot culture (*Paradu*).—The great value of the majority of these Roses is that they may be grown in what are practically cool-houses—i.e., in houses in which a little artificial heat is given at night or in cold, frosty weather. The four kinds you name are excellent, but *Esmeralda*, *Augusta Victoria* succeeds best where a rather high temperature can be given. *Caroline Testout* and *Belle Siebrecht* are two splendid kinds, and may well

PLANTS AND FLOWERS.

INDOOR PLANTS.

PHLOXES FOR POTS.

We often read of some subject or other that it is now too late for propagating this season, and if the increase of the Phloxes was recommended in the usual way and without justification, the remark may equally apply here. The object of rooting some cuttings of the late-flowering Phloxes now is the desire to possess some greater variety in the greenhouse and conservatory from flowering plants other than the Chrysanthemum. It is probably twenty years ago since I took the above in hand in May and June, and so great was the success that for some years I had plenty of fine spikes of the decussata section long after the collection in the open ground had finished blooming. In other words, the plants came into flower with the Chrysanthemum. There is not much difficulty in the way. To begin with, when it is desired to secure late-flowering Phloxes in pots, from the middle to the end of May will suffice for the first batch, and onward through June for a successional lot of cuttings. Generally speaking, there is a hot bed in working at these times, and no propagating-house is half so good as this frame for increasing these Phloxes. Where a Cucumber or Melon-pit is at hand nothing could be better, as the frame at once dispenses with any idea of pots or the necessity for such in the propagation. All that is required is an inch of pure sand placed at the lower end of the frame, and the cuttings, made of the young tops from plants in the open, trimmed up as usual, should be gently thrust into the sand and well watered in. With light sprinklings almost daily, the cuttings, which must be of quite soft wood only, will form roots in about three weeks. If hard and woody they may remain unrooted for months. Immediately the cuttings are well rooted lift and put into 3-inch pots, using rich turfy loam with about a third of decayed manure and a nice bit of sand. In another month or less the plants will be ready for 7-inch pots, and in these they flower, each plant producing a solitary yet very fine head of bloom if the treatment has been good. The treatment may be summed up briefly, and may be likened to growing Chrysanthemums for large blooms. The Phlox, vigorous by nature and making large quantities of root fibres, must suffer no neglect. Firm pitting, rich soil, generous surfacing and after treatment, are the items calculated to produce fine panicles of bloom in October and early November from these plants, and this in convenient sized pots. The plants will be about 3 foot high, possibly less, and depending on the kind. Not only are these Phloxes admirable when so grown for the greenhouse, but for planting out and flowering the year following in the open border have much to recommend them. Indeed, in some instances they surpass the established ground clumps, and the flower heads of bloom produced are of the finest description. E. J.

CLIANTHUS PUNICEUS.

SELDOM does one see this attractive climber, but when growing in a cool greenhouse on the roof—or even a better situation for it, the back wall of a cool lean-to house—it is humming when in bloom. I say cool-house advisedly, for it is the simple conditions necessary to the Clianthus where success may be looked for, not needing a warm, close atmosphere, which engenders green-fly. The blossoms are borne in bunches, claw-shaped, colour earmine passing to crimson, and when seen hanging amid the clusters of abundant foliage are very beautiful. Many who attempt its culture fall into the mistaken notion that it needs heat to bloom it, hence they are never successful with it. Only during severe frost and snow does it require protection, and then, if in a house, just sufficient warmth in the pipes to dispel frost, or a mat covered over it is enough in most houses. If planted out-of-doors on a warm wall, it should be where a covering of some kind can be given it, as continuous snow and frost are harmful to it. It is admirably fitted for growing in a glass corridor, or, as stated, in a cool-house, and for this reason is sometimes seen on the back walls of late vineries, where little heat is needed. The Clianthus does best in a rich compost, and in potting one should be satisfied that it has ample drainage. Any nurseryman dealing in greenhouse climbing plants will be able to supply a Clianthus, and those who are short of creepers for a cool-house, particularly for a wall, cannot do better than plant this handsome subject. The Clianthus may be propagated from cuttings in a compost of peat and sand under a bell-glass or pit. Clianthus puniceus is very attractive also grown as a pillar plant in a cool conservatory. LEAHURST.

NOTES AND REPLIES.

Palm falling.—Would you kindly give me the reason of my Kentia Palm fading at the ends of the leaves? I water once a week. It is in a room with plenty of sun.—LAVAYS.

[Your Palm has evidently been allowed to get dry at the roots. Palms need a soil composed of two parts loam to one of leaf-mould and a little sand, a fairly close rather than a draughty structure, frequent syringing, and shading from all direct sunshine. No hard-and-fast line can be laid down when your Palm should be watered, as this is influenced by weather, position, and other particulars. It may, however, need water about once a week in winter, twice a week now, and perhaps in the height of summer every day will not be too much. The condition of the soil must be your guide in this respect. Water should be given to keep the soil fairly moist, and not at all soddened. The leaves may be washed with soapy water.]

Climbers for conservatory.—I shall be much obliged if you will kindly name about a dozen climbing plants suitable for covering the walls of a conservatory, where they would have to be potted up, as the floor is boarded? The conservatory opens to the south and west, and is not heated. I shall also be glad to know what size of pots should be used?—JEANIE GIRL.

[The following should suit you: Abutilon strictum, yellow, veined red; A. vexillatum,

viriegatum, yellow flowers, pretty variegated leaves; Clematis indivisa, white; Clianthus puniceus, salmon red; Coehra scamellus, purple; Habrothamnus aurantiacus, yellow; H. elegans, cherry red; Lonicera sempervirens minor, red and yellow; Passiflora Coustaree Elliot, white; P. Imperatrice Eugenie, violet-rose; Plumbago capensis, porcelain-blue; Solanum jasminoides, white; Tacsonia Van Volxemii, magenta-scarlet; Thibaudia acuminata, pinkish, wax-like. Pots from a foot to 14 inches in diameter will be needed to keep the plants in good condition, and as they get full of roots a little assistance during the growing season in the shape of liquid-manure or some of the concentrated manures that are now so much used will be of great service.]

Celsia cretica.—This is a most attractive plant when well grown, its long spikes of pale yellow flowers harmonising well with most things. When the plants are in a vigorous condition the spikes of bloom are 2 feet or more in length. Recently I was charmed with its value for winter and spring blooming. In this case it was used in a house, arranged with other spring-blooming plants, such as Freesia, Hyacinth, Primula obconica, P. sinensis, Arums, and a host of other bright showy plants, and its yellow spikes were very conspicuous. This Celsia is of the easiest culture and just suited for amateurs. Some grow it from cuttings, but this is not the best way, as seedlings are far more vigorous. The plants above referred to were raised in this way, the seed having been sown about the end of April. The seedlings when large enough were pricked off in the usual way, and as soon as they were strong enough transferred into small pots, and in early autumn potted into 5-inch and 6-inch pots and kept in cold pits as long as the weather permitted, when they were transferred to a cold-house and removed into the house above described when coming into bloom. This Celsia thrives best in a good, sandy loam.—P.

Striking cuttings of Malmaison Carnations.—At this time of the year, when the side growths are plentiful, it is well to thin them so that those remaining shall develop strongly for layers later on. These cuttings are often thrown away, which is waste, as they root readily. If a little bottom heat, such as a partly-spent hotbed, be available, we have a place that suits admirably. Failing this, I find no difficulty in rooting the small cuttings. They are pulled away from the older plants, and not touched with the knife, and are then dibbled thickly into shallow boxes, using a light compost of sifted leaf-mould and loam. Stencil them in a place where little air can reach them, and shade from bright sunshine. Sprinkle the cuttings daily as well as attend to watering the soil, which must not be allowed to get dry. A few of the outer leaves may turn brown, but so long as the inner portion of the cutting is green I do not trouble. They root and begin to make fresh leaves when each is potted separately, and they soon become established plants, and by the autumn will have passed the layers in size. Such miffy kinds as Nell Gwynne (the white Malmaison) and Mrs. Martin Smith are propagated in the manner

above described. I have known failures when the cuttings are put into a close propagating-lux, but seldom if into a frame or the more open atmosphere of a greenhouse.—H.

OUTDOOR PLANTS

NOTES FROM A DEVON GARDEN.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—We have not had twelve hours' rain in the whole of "the merry month of May," and we are in high summer, as understood in our corner of the world—S. Devon. To paraphrase, "Summer stands full grown, on the knees of Spring." It is the most perfect time of the year for a S. Devon gardener, for there is still some moisture in the earth, so the flowers bloom whilst they may. Another month, and only Carnations can stand the heat. I am writing now—9 p.m.—with a great bowl of Tea Roses in front of me, listening to the song of many birds, soft twilight creeping over the crimson sky, the rich scent of Lilac and Hawthorn coming in through the open windows. Spring lingers, for still one can find Primroses, and the woods are blue with the wild Hyacinths; but the Magnolias are in full leaf, and the glory has departed from the Rhododendrons. Only the late ones are left, and they seem out of place when the Roses come—truly queen of flowers. Everything seems fuller of bloom this year. I have never seen the "common" shrubs and trees, like Weigelas, Lilacs, Hawthorn, snowy Mespilus, Cherries, Ribes, etc., so loaded with bloom. The Roses look clean and healthy. The Banksian has been beautiful. It blooms here early in May. Sweetest of all Roses, the "type" rugosa, is in flower. Not even the old Cabbage can compare with it for "bouquet." The Liliams are both early and vigorous. *L. auratum* stands some 4 feet high, and the flower-buds can be seen. *L. Krameri* is enjoying the dry heat. I have seen several of mine with three flower-buds—a rather rare occurrence. They stand over 3 feet high. *L. Henryi* is "5 feet and still growing," whilst *speciosum* looks like the proverbial Cabbage. I have only tried two new Liliams this year—100 *L. Alexandra*, all up, strong and healthy, 100 *L. rubellum*, only three: both lots imported from Japan. Tulips have been glorious. Paeonies are covered with buds, the early "type" ones flowering well. Flag Irises are unusually fine; English and Spanish ones are thick with flower-buds.

My "blue garden" had out-grown its old quarters, so last autumn it had a real garden to itself, such a pretty sunk garden, nestled into the edge of the wood. Here *Myosotidium nobile* reigns, not quite supreme, but a glory in its own section—the Borageworts. It opened its first flower May 3rd, and looks like seeing June out—two plants with six flower-spikes. It is perfectly satisfying. If one tried, one could not make a plant with such a just balance of simple strength and beauty. If it never flowered it would be still beautiful because of its foliage. I grow it in pure sand, with leaf-mould, in partial shade. At the sunny end of the garden lives *Leschenaultia biloba major*, four plants, one about 14 feet high. Except in *Gentiana verna* and *Witsonia corymbosa*, there is no such blue, not even amongst the Scillas. It has the excellent habit of throwing out flowering shoots in succession all up the main stems, which look like Heath. It has not stood out last winter, but has to face next one. A far cry! *Witsonia corymbosa* has been outside all the winter without protection. In growth it suggests a small, narrow-leaved Palm. The flowers are an exquisite lilac, in short sprays, not unlike *Gentiana verna*, but not so large, neither has it a long tube. My plant lost its top growth in the bitter weather of February, so is now a little bush some 7 inches high, very much alive. *Gentiana verna* seems as if it were well established, for a patch, some foot square, has flowered for many weeks, and has spread. So has *Gentianella*. This has been covered with bloom. Both kinds are difficult to keep in our hot soil, whereas *Agapanthus* is quite hardy. I am very proud of *Meconopsis autumnalis*, for it is covering its decidedly tiny bush with

glory and flower-buds. I have not been able to hear of anyone growing it satisfactorily outside. *Solanum crispum* is in flower (not on a wall, though facing south). So is *Gerbera Jamesoni*, at its foot. *Clianthus puniceus* is very late this year, but is far finer for this, the plants being covered with bloom. I have a strong plant of *C. Dampieri*, but not flowering yet. I dare not trust this outside. Perhaps you may remember my saying a young 10 feet high tree of *Paulownia imperialis* started into bud about September. It has carried those buds all the winter, and to-day—the end of May—has opened the first flower! Is not this singular? Yesterday was an exciting day, for the first flower of *Incarvillea grandiflora* opened. Till then I feared it was *Incarvillea Delavayi*, of which I have 60 flowering plants. There are five strong plants with eight flower-heads. I still can hardly understand how I was allowed to buy them, for I bought them for a song at an auction as *grandiflora*. I fancy very few people have it yet. It is beautiful, though my flowers open with a clear yellow throat (inside), only becoming white with age, for yesterday's bloom is

severo winter, but *B. madagascariensis* was cut to the ground; it was in the open, not on a wall. It has broken all right. *Banksia quercifolia* looks as if it were really an Ilex, and is setting its quaint—what? Flowers—comes? I don't know what to call them, except the "things" that contain the seeds. *Acacia dealbata* (*Mimosa*) flowered as well as in the south; so did the rarer Olive-leaved one. The *Erythrina* are pushing up their new shoots, and *Ixia* and *Sparaxis* are beginning to flower. All these stand our winters without any protection. If only I could have a kind of shower-bath over about an acre of ground to grow cool-loving things! A semi-double crimson *Camellia*, grown as a bush about 5 feet high, is setting an unusual number of fruits. A. BAYLTON.

Dwarfish.

LILIUM TESTACEUM.

THIS is one of the handsomest of hybrid Lilies. The present illustration gives ample proof of what value a good Lily is to the garden, and in a case such as this, when the plant will grow and flower well, even in town areas, the result more than repays the years of patience and

The Sankeen Lily (*Lilium testaceum*).

now white about the edge near the lip, and doubtless fades white all down the tube. The colour is pure rose. After such a lovely novelty it is nothing to speak of *Eremurus*: still, it is my first bloom of *E. himalaicus*. I suppose a baby one, for it is only some 5 feet high, but the flower-head is about 18 inches now, when half opened. I have five heads of *E. Bungei*. The *Cistuses* are covered with flowers. *Carpenteria californica* has set a great many buds, whilst *Genista odorata*, the greenhouse kind, is pure deep yellow all over its 9 feet of growth. I find one great advantage in living in a waterless land. Cushion Irises are nearly as happy as in Asia Minor. The first flower of *Iris susiana* is nearly open this evening. A limeless soil, no protection of any kind, yet this is its second flowering. Several other Cushion Irises are in bud. The early *Calochorti* are in flower; *Ornithogalum arabicum* has its flower-head several inches above the ground; *Lonicera Hildebrandi* stood the winter nobly, a young plant in a 5-inch pot sunk in the open. It is now coming into leaf. *Burdeia Lindleyana*, *B. japonica*, *B. variabilis*, and *B. Colvillei* took no notice of the winter

waiting. Of the general appearance of the above plant the picture speaks more plainly than words, and one can only add a note as to the delicate colouring, which has been called "nankeen" by reason of the flush of red that pervades the delicate apricot in certain stages of the flower. The parents of this fine Lily have been suggested as *L. candidum* and *L. chalcidonicum*, and certainly the habit of the former is well seen in the hybrid, while the great reflex of the fully open flowers would probably be taken from the other kind. In stature the hybrid leans strongly to the beautiful Maltona Lily, and when established, rising to 6 feet or 7 feet high, it is a fine plant indeed. It is a Lily for everyone to grow, albeit it fails now and again. As to soil and position, the latter must be perfectly drained, and the soil a deep bed of loam made very sandy, and a slight addition of peat, if at hand. Good leaf-soil may be employed also, but not the third-rate article to which often the name of leaf-mould is given. As to soil, however, the plant is not fastidious, and in a raised position in strong, rather clayey loam I have seen it flourish perfectly. Manure

ould not be employed, and if the soil is good it is not wanted. It flowers in early July, or possibly in June now and then. E. J.

MY WILD GARDEN.

AFTER reading various accounts of "wild gardens" in your valuable paper, and seeing what had been done at a friend's place with ground formerly occupied by Nettles, it was an easy task to try to improve a naturally beautiful spot. There is a wide glen adjoining the house, above which rise the hills to the height of 1,500 feet, and through which runs a "burn." Along the steep sides of the glen are coverts for game, enclosed by fences to keep out the sheep and cattle. One of these I fixed on for a "wild garden." It was difficult of access, owing to its steepness and from being shut off by a little stream which runs into the burn below. The first thing (with the help of a son and daughter) was to make a little bridge over the streamlet, and a narrow path which runs along the steep side of the bank, coming down to the burn and back to the bridge. This path is very rough, with rocky steps here and there. Then two seats were made, and irregular borders dug out, banked up with mossy stones and filled with leaf-mould. I procured some alpine plants, but, alas! rabbits and slugs made short work of them; but other things are more fortunate. There are already Primroses, Violets, and Ferns, and I have planted quantities of Daffodils, white Pheasant's-eye Narcissus, white Foxgloves, London Pride, Saxifrage, and, best of all, Lily of the Valley, which are doing splendidly. Later on come great masses of yellow Broom, and Rowan-trees brighten the place in the autumn with their scarlet berries. My husband has had a wooden summer-house built, in which tools are to be kept and shelter afforded from the drenching storms we have in this hilly district. During the long frost of last winter a wild roe-deer found her way from the hills to this sheltered spot, and a few days later was found dead there. Black game come to sit in the Birch-trees, and this is the second spring that a sand-piper has hatched out her family near a large clump of Primroses. The place needs very little attention. Some salt is strewn on the paths to keep down weeds, the edges of the Grass are cut by a boy from the village, and a little hand-weeding is done among the rough borders. It does not look so well in summer, as the Grass grows so long and rank, but at this time of year, on a fine day, the sight of the shadows on the hills, the peaceful sound of the sheep and hanks, mixed with the rippling sound of the burn, and the scent of the flowers in the foreground, combine to make the "glen garden" delightful. Would you or any of your readers tell me of any hardy plants to flower in August that rabbits and pheasants would not eat? Leamark, N. B. CASTLECAIRNS.

much vigour, which results in the flowering period being of short duration. The names of a few striking kinds are Demon, dark maroon; Miss Roberts, yellow; The Bride, white; Victoria, white, edged crimson; Polly Eccles, fawn and crimson; Northern Star, red and buff; Aurora, amber; Amos Perry, maroon; Beauty's Eye, lilac and red; Phyllis, white, flaked crimson; Jack Sheppard, yellow, striped red; and Naomi Tighe, yellow and red.—H. S.

DAFFODILS AMONG BEECH-TREES.

The drift of Narcissus seen in the illustration is *N. poeticus ornatus*, and was planted two years ago—12,000 bulbs with 6,000 *N. p. Pheasant's-eye* further on, the whole covering about an acre. Though our hot, dry, sandstone soil is decidedly against such bulbs as Daffodils, still, with care, we succeed with them. Leaf-mould as a mulch, with bone-meal and basic slag as manure, is a great help,

beautiful blossoms on a most unsuitable habit of growth, and others possess blooms of poor quality on a charming tufted habit. The colours, too, are very varied, and one may desire to raise plants of ideal habit which develop flowers of distinct shades of colour, good in form, and with plenty of substance. The value of these plants is undoubtedly enhanced when they possess a robust constitution, and, with this, all or part of the good points just mentioned.

1. This is a very simple matter, and one which you may easily carry out. We would advise you first of all to definitely fix upon the plants you intend to cross-fertilise, observing the points previously considered, so that there may be good reason to expect advance in the resulting progeny. You would then be well advised to enter up the proposed crosses in a book set apart for the purpose, giving to each cross a number, and associating with the number wool of a certain colour, varying the colour in each instance, so that the respective

The Poet's Narcissus in a Beech wood. From a photograph by Mrs. A. L. Baydon, Oaklands, Dawlish, Devon.

and is neither expensive nor troublesome to apply. We do not know what disease means, and the plants increase freely, both by bulbs and seeds. They are not in Grass, but Ivy, "wood growths," and a perfect carpet of Primroses. A. B. Dawlish, Devon.

FERTILISING PANSIES.

I should feel very much obliged for a little advice through your paper on the cross-fertilisation of Pansies and Violas. 1. How could I cross-fertilise the plants so as to know accurately from which two a certain seedling came? 2. At what stage in the opening of the flower should fertilisation take place—when just open, or full blown?—G. N. HAWKLEY.

The majority of the sorts now catalogued by the specialists and others are the result of chance, and this is the reason why we do not see the advance in habit that is so desirable. Before commencing, it is essential that you should have a good representative collection of the better known and up-to-date sorts, and make yourself familiar with their peculiarities. The habits vary considerably; some have

colours may be identified with a particular cross. The small lengths of wool are used for tying round the flower-stalk of a blossom which has been fertilised, and in this way denote by their colour the cross which has taken place. By these means you should have little difficulty in accurately ascertaining from which two crosses a certain seedling came. As the seed-pods ripen and are gathered they should be placed in a small bag, and the letter numbered to correspond with the number associated with the particular cross. At the subsequent seed-sowing and planting out the labels should be numbered in like manner, and in this way the parentage of the seedlings determined.

2. As you propose to work in definite lines it is important that self-fertilisation of the flowers should be avoided. The only way to prevent this is to remove the pollen of the seed parent without injuring the pistil. Little instruments are made for the purpose just referred to. They are of bone, about 3/8 inches long, and less than a 1/4-inch wide, bluntly pointed at one end, and hollowed out a

little so that the pollen grains may be gathered from the anthers. Pollen may then be transferred freely from one flower to the other by the aid of a small camel-hair brush.—W. V. T.]

NOTES AND REPLIES.

Flowers in May and June.—Being a regular reader, I should be greatly obliged if you would kindly name a few flowers that I might raise from seed sown now that will bloom next May and June? I want to grow them on a south-west border for table and room decoration.—W. L.

[You ought to plant in the autumn Gladiolus The Bride, Spanish Irises, double Narcissus poeticus, Scilla campanulata, all of which would flower at the time you say, and be very suitable for room and table decoration. The above are all very cheap and easily grown. You could also sow Pansies, planting these out in the autumn, as also Iceland Poppies, Myosotis. Try also some Sweet Peas, raised in the early spring in pots, or sow a few in the autumn. You could also sow the Cornflower in the autumn, while many annuals, provided they escape the winter, would also be useful. If you want any light material to go with the above, sow the annual Gypsophila early in the spring.]

Carnations.—I enclose leaves of Marguerite Carnation seedlings, and shall be much obliged if you will please tell me whether there is anything the matter with them, and what is the remedy? I raised two separate lots of Carnations from seed last year, and both were affected with disease—I think rust, but I am very wishful to grow these flowers, and so I began again this spring with a fresh lot of seed. The plants are now in 3-inch pots, and have come on very well, and I shall be much disappointed if anything goes wrong with them now. I planted out a bed with last year's plants—now diseased. Can I remove these and replant with my new seedlings without infecting them also, by treating the soil in any way? Will you please tell me, also, how to treat the plants next autumn? I want to take layers from the best sorts. Can this be done in the bed where they flower? And can the old roots be left in their places through the winter to flower next year?—J. P. T.

[Your Carnations are evidently attacked by spot, to cure which no remedy has yet been found. If you wish to grow Carnations, you must never grow two years in the same soil. Either move to fresh quarters or clear away the old soil and substitute fresh. It is far best to increase by layers every year, throwing away the old plant. The Marguerite Carnation is an annual. A good plan, when you wish to increase Carnations and do not wish to layer the plants you have in the flower-garden, is to plant some in the reserve garden, cutting the flowers as wanted and layering as early in the season as you can, so as to get well-rooted layers to plant out in the autumn.]

Asters destroyed by insects.—Last year I had nearly all my Asters killed through an insect eating through the leaves, and in some cases eating the young plants altogether. I have just put out my plants, and I want, if possible, to prevent it this year. Can you advise me?—G. W. B.

[The only way to combat the pest is to render the plant more or less unpalatable to the destroyer. In the first place we suggest a free dusting of soot about the plants, particularly on the top surface and about the collar of the plant. This may probably check the foe. You may also syringe with soot-water, taking care to wet the entire plant. If this is not successful, then you may try Quassia, one application of which should be sufficient for ten days at least. Prepare the Quassia as follows: The Quassia-chips are to be had of the chemist or, preferably, the horticultural sundriesman. Take a 5-inch potful of the chips and place in any old saucepan or pot, and one gallon of rain-water, gently boiling the same until the Quassia-chips all sink to the bottom. This may take twenty or thirty minutes over a steady fire. Afterwards strain off the liquid and add at once 4 oz. of soft-soap, which dissolves in the hot water. Add a wine-glassful of paraffin, and whip the mixture into a froth. Now add two more gallons of rain-water, and one of the most cheap and efficacious insecticides is ready for use. Employ a syringe with the finest spray possible, and endeavour to reach all parts of the plant. This mixture is excellent against the attacks of thrip and red-spider.]

Plants for late autumn.—I have two borders planted out this summer with Geraniums, Fuchsias, Asters, French Marigolds, and I have also Sweet Peas and some wall trees. I want to know what I could put in or get ready to put in for late autumn flowering. Could you advise me? Beds about 16 yards long and 3 feet wide.—G. W. B.

[Seeing that some of the plants—Asters, Marigolds, Geraniums—you have already

planted flower on into the autumn, it is not easy to deal with the above—at least, in a satisfactory way. There are many good autumn-flowering subjects, and had all the other things been so early-flowering as the Sweet Peas it would be more easy to deal with the borders for late work. Probably the finest of all late-flowering plants is the Tuberous Begonia, and such as these could be grown in pots or boxes and transferred to the beds when the main flowering of the other occupants was completed. The Begonias may be still had in the dry tubers, and nothing transplants more readily. The transplanting, indeed, is the chief difficulty in the case. As for material, we may mention many Michaelmas Daisies, Pompon and Cactus Dahlias, Zinnias, Rudbeckias, early-flowering Chrysanthemums, etc., all of which would, however, have to be grown in pots for a long time, and cause a considerable amount of labour to keep them in condition prior to planting. Nor do we see that you can do much by sowing annuals, unless on the same lines of culture. What we imagine to be your best plan will be at once to sow Asters of the Comet section, with Zinnias, pinching these latter once when 8 inches high, to form a late-flowering batch. Sow, also, seeds of Mignouette, half-a-dozen seeds in a 5-inch pot only three parts full of soil. Sow, also, in the end of June seeds of *Alyssum maritimum* in pots, and with Begonias fill up the spaces as these become vacant or unsightly.]

Sweet Peas—planting out too early.—The present spring has shown the fallacy of planting out seedlings raised in pots too early. A capital lot of plants was raised in pots and nicely hardened off. The more genial weather experienced in the earliest days of April induced me to commence putting the seedlings into their flowering quarters. The young plants were then some 5 inches or 6 inches high. For a week or rather more all went well. Early morning frosts tried the plants severely, but they seemed to stand them, especially as the weather was fairly genial subsequently. It was in the last fortnight in April, however, that the more trying climatic conditions prevailed. The cold, cutting easterly winds were continuous and exceedingly boisterous for so late in the season, and during this time the plants looked anything but happy. My garden, being situated in a very open and exposed situation, felt the full force of the winds, and that some shelter might be afforded them boards and other contrivances were stood on edge to protect the plants. Some of them have quite a blotched appearance, and at the time of writing it seems almost hopeless to expect them to recover. I am hoping that with a change of the wind and some warm showers they may improve. These experiences prove how imprudent it is to place the young plants in their flowering quarters in open and exposed positions until quite late in April, or until the weather is more settled. In warm situations, where adequate protection from cold winds can be afforded the plants, earlier planting out may be carried out.—C.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS OF A BUSHY HABIT.

DURING the earlier part of the present year numerous requests were made by readers of GARDENING ILLUSTRATED for information as to how to have Chrysanthemums of a bushy and free-flowering character of growth. Growers were told to pinch out the points of their plants—represented at that early period by a single stem. As a result of this treatment the plants would branch out into several new shoots, and there is every reason to believe they are now represented by specimens carrying several healthy shoots, some inches in length. In the replies we then gave it was recommended to pinch out the point of these lateral growths when they had attained a length of about 6 inches, and each succeeding 6 inches of growth were to be treated in a similar manner. Subsequent to each of these pinchings the plants would branch out into other growths, and in this way fine specimens would be developed. Just now some of the shoots that developed as the result of the first pinching are now ready to be treated in like manner.

It is a good plan to keep the plants rather at the roots for a few days after pinching; this treatment induces the new growths to develop quickly. For ordinary November displays we should be disposed to pinch the plants for the last time at the end of June, from the period allowing them to develop their growth in a natural manner, flowering the plants into the terminal buds, which are the last to develop on the plants. Just when the new shoots are forming, green-fly often gives trouble, but it is easily got rid of by dusting with Tobacco powder. Avoid finally potting and pinching the plants at the same time—at least a week should intervene between these operations. During the summer and early autumn give the plants plenty of room in the standing ground. A good open, sunny position is ideal for the purpose, and there should be sufficient room to enable the grower to examine his plants with comfort. Give each plant the support of a stake or Bamboo cane, and secure the latter with strained galvanised wire, as a check against strong winds. E. G.

EARLY-FLOWERING CHRYSANTHEMUMS.

SEASONABLE HINTS.

ALTHOUGH weather of late has not been all that the grower could desire, the plants have done fairly well. Early planting has been at a disadvantage this season, the cold and trying weather of last month keeping the plants back. The copious rains of the last few weeks have worked wonders, growth in consequence being rapid. The growths, however, are very brittle. In the neighbourhood of London on Saturday, June 7th last, a heavy storm, accompanied by hail, did considerable damage to many of the best plants, their brittle character making the growths susceptible to damage from the large hailstones which fell in large quantities for some time. Many plants were broken off, and presented a woebegone appearance after the storm had passed over. Given a spell of nice warm weather, the damaged plants will quickly produce numerous lateral shoots, and in this way the plants should be bushy specimens. In exposed situations late frosts are giving some trouble, although with plants which have been out for some weeks now there is no cause for alarm. The time has now arrived when the plants should have the support of a stake of some sort. Stout Hazel rods are the best, although the Bamboo canes, now so freely used, are strong and clean. The Bamboo canes, however, do not seem equal to the strain put upon them when the late summer and early autumn winds are troublesome. Do not insert the stakes too near the main stem of the plant, and when placing them in position see that they are well embedded in the soil. If this advice be disregarded, the weight of the plants later, together with the strength of the south-westerly gales, may cause many of them to topple over, and possibly snap off. Securely tie the main stem at its base—at least, a few inches above the level of the soil. Some of the shoots may be infested with green-fly, but this is easily eradicated by a dusting with Tobacco powder. Keep the hoe busy between the plants, thus aerating the soil, and thereby encouraging healthy root-action. Weeds, too, which are very plentiful just now, may also be kept under by the same weekly hoeing. Poor soil in wet weather should have an occasional sprinkling of some well-known and reliable fertiliser. E. G.

Chrysanthemums Avalanche and Vivand Morel.—These are two old favourites which I think amateurs especially should strive to grow when decoration is the main object. They have both excellent constitutions, and may be planted in the open during summer, lifted and potted in the autumn, and make a rare show on to the New Year. They are not particular as to soil, provided they get a little feeding, but care should be taken never to feed a plant when growing in the open until all the buds are set, as otherwise you get rank, useless growth and probably "blind" buds. The colour of Avalanche is a beautiful pearly white, and that of V. Morel rosy-pink. It is a large and beautiful flower, much prized a few years ago at an exhibition variety.—D. G. McIVER, Bridge of Weir, N.B.

ROSES.

ROSE TRIOMPHE DE RENNES.

WITHOUT doubt this is a charming Rose when one can grow it. Many years ago, before we had such fine yellows as Jean Pernet, Mme. Rose, etc., this Rose was thought much of, but somehow of late years it appears to have deteriorated. The best flowers I have ever seen of this variety were from a plant bodded upon an old Hybrid China named Vivid. A young shoot was selected near the base, and the buds inserted. The next summer all the young shoots were rubbed off this one growth, and handfuls of lovely creamy-yellow blossoms were cut from the resulting growths. Unfortunately, the Rose succumbed to the severe frosts that followed. I have also grown it most successfully upon the old Monthly Rose—in fact, Triomphe de Rennes, if grown outdoors, appears to require a foster stock in the form of an old-established Rose, such as the kinds named or the Yellow Banksian. Cultivated under glass, where it really is most successful, it yet remains a beauty. I should much like to see its culture revived. At present it appears to

reached, as we were informed some time ago that nothing further could be expected from the Hybrid Perpetual group. A thorough system of cross-fertilising the Hybrid Perpetual is capable of completely changing and improving the group in the same marvellous degree as in the case of the Hybrid Teas. Some will argue that Roses of the Lady Mary Fitzwilliam type should be banished, forgetting to what extent this wonderful Rose has changed the aspect of our collections during the last ten years. The important question will doubtless be raised how far hybridisation is responsible for want of hardiness in some of the Hybrid Teas, and this matter deserves special consideration. Since pergolas became the rage Rambler Roses have been largely grown. This, in part, is due to the distribution of Crimson Rambler. But the public desires something to tone down the garishness of the Crimson Rambler, and in some degree they have found the desired varieties among old-fashioned Roses, such as Felicité-Perpetue, Flora, Aimee Vibert, and among modern kinds, such as Aglain, Thalia, and Euphrosyne. The beautiful single Rose, Rosa multiflora, was employed to produce these

kinds. Moss Roses, too, are open to improvement, more especially those known as perpetual Mosses. I have never yet seen a Perpetual Moss worthy the name. Single Tea Roses are only in their infancy. I perhaps should say single Hybrid Teas. I cannot see why some magnificent singles rivaling R. gigantea are not possible with an ever-flowering characteristic hitherto wanting in most single Roses. Then, again, as to sports. Is there anything we can do to encourage these? Some of our most beautiful and popular Roses are sports. I notice a great tendency to sporting in hybridised Roses, also upon plants grown in very large numbers in one establishment. Mrs. W. J. Grant was not introduced many years before we received the splendid strong climbing form. The same remark applies to Kaiserin Augusta Victoria, and I believe there is already a climbing Liberty. The popular Lady Roberts is reputedly a sport from Anna Ollivier. Another important question arises regarding the climbing forms of certain Roses, and that is, whether it be possible to obtain, as it were, intermediate forms. I had last season many plants of climbing Mrs. W. J. Grant run back,

Rose Triomphe de Rennes. From a photograph by F. Mason Good, Winchfield.

have dropped out of most lists. I believe an own-root plant in a good border in a warm-house would be a good method of cultivating it, or insert some buds upon a Gloire de Dijon or any good Rose that happens to be growing under glass in a convenient spot. There is another old Rose I should much like to see revived named Smith's Yellow. It is almost identical in its erratic behaviour with the Rose under notice, but would well repay looking after under glass. So many lovely Tea and Noisette Roses are practically greenhouse kinds. They, however, deserve any special treatment one can afford them, if only to be regaled with their beauty in early spring.

ROSA.

THE COMING ROSE CONFERENCE.

AS the date approaches for the Rose Conference, which will be held at Holland House under the auspices of the Royal Horticultural Society, those who are interested in Rose growing naturally have their thoughts directed to the event, and perhaps some may speculate as to the outcome of such a gathering. Undoubtedly the advance of the Hybrid Tea will be the main topic, with perhaps that of the Rambler group. We shall probably be told that improvement in the Hybrid Teas has been

three, and others similar, and now we are receiving lovely single forms from it, such as Leuchtstern. I am convinced the more we employ R. multiflora for cross-fertilising the better will it be for our gardens. But, unfortunately, in this group we have not yet obtained a habit of second flowering. R. Wichuriana, too, has made great advance, thanks mainly to our American friends. This group will doubtless be still further improved. The latest hybrids produce really beautiful Tea-like blossoms, but it is questionable whether such kinds are really improvements. I think I would prefer the type in its procumbent form, with a variation in its colouring and without the departure from the single blossom to the double. We have plenty of the latter in the fast-growing Teas and Noisettes. R. canina, our hardy willing, appears to me to be much neglected. In the variety Una, a cross between R. canina and a Tea Rose, lovers of single varieties will find a very excellent introduction. There are several species well worth the hybridist's attention, such as R. setigera, R. lutea, and its copper form, R. levigata, which already has given us the lovely R. sinica Anemone, the pretty Scotch Roses, more especially the single forms, R. alba, and a host of others all capable of giving some fine

as it is termed, but such plants were much stronger than the original dwarf type. I have had the same happen with Climbing Niphotos, Climbing Perle des Jardins, and Climbing Devoniansis.

The question of Roses on their own roots should be taken up in a manner worthy of the subject, and not be dubbed the "dream of journalists," which a well-known Rose grower has thought fit to call it. As the journal of the Royal Horticultural Society has such a wide circulation, some unusual cultural hints should be of much benefit, and especially if gardeners who have charge of large collections of Roses gave their experience. Taking climbers, the public should be warned that patience is required before the beauty of such can be fully seen. So many individuals desire to see a house wall, a pergola, a pillar, or an arch covered in twelve months—an impossible feat for a Rose. Another interesting subject that a gathering of Rose growers could give some useful information upon is the retarding of Tea Roses by growing them upon north borders, also the protection of same by heeling in under north walls. Roses for market, too, should be discussed. Fragrance in Roses appears to require a definition, at least, the various degrees of fragrance. Our senses tell us there is a difference,

but we are at a loss how to define it. I think encouragement should be given to the cultivation of some of the lovely old varieties of the Hybrid Chinese groups, that were the embodiment of hardiness, vigour, and free blossoming whilst they lasted. And, lastly, there are the ever present subjects of insect pests and fungoid diseases that seem to baffle the experts. I refer more especially to canker in *Marechal Niel*. I should gladly welcome opinion on this important subject, and also on another scourge—namely, red rust. Mildew outdoors seems to huddle us, and probably will do so until we obtain a mildew-proof race of Roses. I think if some of these questions were treated in a manner that one would expect from such a conference, they would be of more value than long botanical dissertations concerning the Rose. However interesting this subject may be to a few, the culture would appeal to the many. ROSA.

NOTES AND REPLIES.

Briers budded last summer.—Last year I budded a number of Brier stocks with some very good Rose buds, and they have just commenced to grow. Can you give me the reason for being so backward? The dwarf ones are at least a foot high. I find that my father has been pinching all the Brier growths off close to the wood, and he says this is right. I say no, and that at least an inch or two to draw up the sapright to him is best. Please say if this is the reason of the lateness?—R. B. H.

[We are not surprised to learn that your luhked Briers are so backward. It is a general complaint, and attributable to the exceedingly cold spring we have had. Now that more genial weather has set in the buds will grow very fast. The pinching of the Brier growths would not retard the buds, but we prefer to leave an inch or two upon three or four of the Brier growths that break out beyond where the bud is inserted more particularly to strengthen the Brier and assist it to make roots. Sometimes the buds inserted in the Briers refuse to break owing to the germ having been pulled out at time of budding. The bark unites with the Brier and is alive, but if, unfortunately, the germ was injured, you cannot expect the buds to start into growth. You must not, however, be in a hurry to cut them back, certainly not for another month. Unless they break by that time we fear there is not much chance that they will do so. Where there is any doubt concerning such Briers it is advisable to retain one or two young shoots on the stem for rebudding should the others fail.]

Rose Marechal Niel in cold greenhouse.—I should be obliged if you could give me any advice about a *Marechal Niel* Rose growing under glass in a cold greenhouse (Glimmer). It has been planted two years, but has never made much growth. This year nearly all the buds have shrivelled and dropped off before blooming.—A. M. D.

[As the plant has never made much growth since it was planted, we should say the fault lies either at the root or in the unsuitable condition of the border. This beautiful Rose will succeed well enough in a cold greenhouse, provided a well-prepared border is made and a healthy plant put into it. So many of the plants sold are reared in strong heat and under most unnatural conditions that it would be a marvel if they succeeded when given totally different treatment. The very best kind of plant for a cold-house is the dwarf or half standard cultivated in the open ground. Let a young, vigorous specimen be planted in October or early November in a well-drained border, and success is practically assured. Of course, canker will sooner or later lay hold of the plant, but if it is not overcropped or excessively manured with artificial such a tree should last for many years. When buds shrivel and drop off something is wrong with the roots. Possibly you have given too much water or the soil has become water-logged. Again, frost may have entered and injured the embryo buds. When Roses are grown in cold-houses they should be retarded as much as possible by affording abundance of air, so that growth is not excited too early. If this happens, and severe frosts cannot be kept out, the young growths are consequently injured. Thick mats or similar material will keep out a lot of frost, and this should always be attended to when the new growths have grown an inch or so.]

Rose Marechal Niel with long growth.—I have a *Marechal Niel* Rose in my greenhouse, purchased this year. It has finished blooming. It has a long stem, which is useless for the first

plenty of leaves on the remaining 7 feet. Ought it to be re-potted and cut back? It is now in an 8-inch pot. Kindly tell me what soil and size of pot you advise? Also, would it be better out-of-doors for the summer?—P. X. H.

[Your plant should be re-potted at once. A small tub would be the best for it, as being a climber one cannot re-pot such plants every year, neither do they require it, provided a fairly large pot or tub is used. Failing the latter a No. 6 or 14 inch pot would be the best size to re-pot the plant into. Give ample drainage to either pot or tub, 4 inches to 6 inches in depth being none too much, and the plant should stand upon two or three bricks or inverted pots, so that water may pass away freely, and at same time air enter the soil. The best compost is two-thirds pasture loam and one-third cow-manure, if possible a twelve-month old, so that it will easily separate and thus incorporate more efficiently with the loam. A 5-inch potful of bone-dust could with advantage be added to a barrowful of soil, and also a little sharp sand. Take care that all is thoroughly well mixed together. See that the compost is not too wet, and if such is the case keep it in an open shed for a day or two. We should not advise you to cut back the plant, but in order to make it break into new growth near the base slightly bend the long growth to the right or left. The greenhouse would be the best place for the Rose, avoiding a draught as much as possible. If you can afford it plenty of heat and syringe twice a day, during the summer some fine new shoots should appear that will give you the good flowers next spring.]

GARDEN PESTS AND FRIENDS.

Hair-worms.—Can you kindly tell me in GARDENING what the little worm or insect is which I enclose? I find them after heavy rain, hanging on to the leaves of plants, and warbling about. Are they harmful to the plants?—C. HARRIS.

[The worm you send is one of the hair-worms belonging to the genus *Mermai*. These worms lay their eggs in the ground, and when the young ones are hatched they obtain access to some insect, in which they live until they are mature. They then quit their host and lay their eggs in the ground. They are perfectly harmless in every way. They sometimes appear in showery weather in large numbers, and may be found crawling about plants.]

Flies on Apple-trees.—What is the enclosed fly, of which quantities have suddenly appeared on my young Apple-trees? And what remedy should I use? The country people here (Surrey) call them Apple-eaters, and say they are always fatal to the crop. Is Paris-green a good thing to use?—R. S. H.

[The flies of which you send specimens, and which you find on your Apple-trees, will not injure them in any way, and can have no effect on the crop. They are very nearly allied to the flies commonly known as St. Mark's flies, and belong to the same genus; their scientific name is *Bilio hortolanus*. Their grubs are to some extent injurious in gardens, as they feed on the roots of various plants, and may sometimes be found in considerable numbers together. As a rule, these flies do not fly well, and are generally found crawling over plants and trees. They usually make their appearance in large numbers. It is of no use trying to kill them with any insecticide, as they would simply fly away as soon as you began to use it.—G. S. S.]

Plague of woodlice.—Would you kindly give me your advice re the most effectual way to destroy woodlice, of which in my garden I have an enormous number, which are doing a lot of damage to the seedlings, nipping them down to the ground, also eating away the stems of the larger plants? I catch as many as I can every evening, but they breed so fast I am afraid it is a hopeless job to keep them under in that way.—A. E.

[One of the best ways of destroying woodlice is to pour boiling water over them if you can find out where they congregate. They are fond of hiding under bricks, slates, tiles, pieces of board, etc. Lay some of these about and lift them every morning. They may also be poisoned by boiling small pieces of Potato in water in which arsenic has been boiled. Phosphorus paste spread on bread-and-butter has also been recommended. Another way is to fold long strips of paper in half lengthwise, and smear one side with treacle and beer, laying them about in the haunts of the woodlice. No insecticide has any effect on them, their skins being so hard.]

The winter moth (*E. C. Storer*).—The fact that the female winter moth occasionally carries the branches of the trees by the male while pairing is well known and is often mentioned in print, and it accounts for trees being to a certain extent infested, even though "sticky banding" had been in every way thoroughly well carried out, but it does not account, as you say it does, "for the ineffectual nature of greased hands," for the number of wingless females caught on such bands is a truly astonishing. I have seen hands which were a complete mass of moths. To all appearance, none of the band was visible. The point that should always be attended to when trees are banded is to see that the bands are not got so covered with moths that they are unable to cross them on their dead bodies. I should advise you to procure some book dealing with insect pests.—G. S. S.

Maggots in Pears.—I send herewith a couple of Pears and should be glad if you will inform me through your columns of a remedy for the disease? In 1901 the trees bore a heavy crop of good, sound fruit. I then, in 1901, manured with good stable-manure, and last year the disease appeared. I gave, in the autumn, a heavy dressing of Kainit, thinking to destroy grubs, but this year the disease is worse—not a sound Pear. The trees are in a small orchard, rough Grass all over, and not large enough to feed down with cattle.—K. W. N.

[Your Pears are attacked by the grubs of the "Pear gum midge" (*Diplosis pyramis*). The fly is quite small, not measuring more than $\frac{1}{8}$ inch across the wings. It is much like a small gnat in general appearance, though it belongs to quite a different family. It lays its eggs in the opening blossoms. The grubs are sent to hatch in the course of four days, and immediately make their way to the core of the future fruit and begin to feed. Naturally the fruit so attacked never comes to perfection. When full grown the grubs leave the Pear falling to the ground if the fruit is still hanging on the trees, or merely crawling out of them if they are on the ground. They then bury themselves an inch or so below the surface, and become chrysalides, from which the flies spring early the next spring. The trees should be well shaken, so as to cause many of the affected Pears to fall as possible, or, on small trees, they may be gathered and burnt or buried deeply in the ground. A heavy dressing of Kainit (about $\frac{1}{2}$ a ton per acre) applied under the trees in July or August has been found very efficient in destroying this pest. The removal of the surface soil to the depth of 2 inches would have the same effect, but the earth taken away must be burnt deeply or burnt, so as to destroy the chrysalides.]

The Pear midge (*H. H. and W. J. Brown*).—Your Pears are attacked by the grubs of the Pear midge. The grubs have now left the fruit, and have buried themselves in the soil, where they will become chrysalides. Had you opened one of the Pears earlier in the season you would have found several little grubs in each. The parent is a small gnath-like insect, about 1-10th of an inch in length, and measuring hardly $\frac{1}{8}$ inch across the wings. The best means of destroying this insect is to pick off and burn the infested Pears as soon as the attack is noticed, and afterwards to give the soil on to which the grubs have fallen when they left the fruit a dressing of Kainit, at the rate of $\frac{1}{2}$ oz. per square yard. This should be done now. If the ground is at all caked on the surface, break it up lightly first and then the dressing in. The grubs will not be more than an inch or so below the surface, so that later on the ground was dug and the surface soil turned well down the flies next spring would not be able to make their way to the open air.

The Rose maggot.—This maggot is very annoying to the Rose grower, boring into the best buds, and destroying many a cherished hope of fine flowers. There seems to be no possibility of escape from it; every year it makes its appearance, and if not destroyed in the spring as it comes to life scarcely a perfect flower will be obtained, especially early in the season. At the time of pruning, every bit of the prunings, with the pups, if any remain, should be carefully gathered up and burnt. As soon as the shoots begin to push, and the leaves expand, the larks will make their appearance, they may easily be detected by the web they spin, coiling themselves up in the young leaves.

here they must be looked for with care and destroyed, going over the trees once a week, raking them with the fingers; for, if allowed to remain, as soon as the buds make their appearance they will spoil them. In confined and over-sheltered Rose gardens this insect much more prevalent and destructive than in the extensive open grounds. The more exposed situations appear to be uncongenial to this and her insects that infest the Rose.

ORCHIDS.

THE QUEEN'S ORCHID.

Among all the Orchids grown in British gardens there is none so chaste and graceful, and so beautiful, and none so delightfully noble as is the *Odontoglossum crispum* of Welby, or the *O. Alexandrie* of Bateman. The latter author illustrated two of the first varieties introduced in his "Monograph of *Odontoglossums*"—viz., Blunt's and Weir's varieties, the one having spotted perianth segments (plate XIV), and the other white ones (plate XIX). *O. crispum* was discovered in 1863 by Mr. Weir, when collecting for the Royal Horticultural Society, at an elevation of 7,000 feet to 8,000 feet, in the damp and shady woods behind the city of Santa Fé de Bogota, in the province of New Granada. Mr. Blunt, one of Messrs. Low's collectors, also found the plant at about the same time in the same locality, and Dr. Triana collected it with the plant growing on the trunks of large and shady trees a few leagues from Santa Fé de Bogota, and also in Pacho, a noted district from whence numerous splendid varieties have since been obtained. By a curious coincidence, in the early days, no less than three collectors sailed from Europe for Bogota in the same ship, and all three brought home plants of this Queen of Orchids. Weir, before mentioned, Blunt, who collected for Messrs. Veitch, of Clapton, and a representative of Messrs. Van der Veken, of Brussels.

The *Odontoglossum* is now-a-days are seen in the or four days' journey from Pacho, the villages of San Juan and El Ortiz being working centres; at the latter place they may be hired to cut down trees and collect the plants. In the dense forests here the trees are clothed with trailing Lichen and other epiphytes, as well as the *Odontoglossums*, and the whole place is dripping with moisture, and the traveller who rides on a mule or walks through these woods primeval is soon drenched through and through. *O. crispum*, *O. Complanatum*, and *O. odoratum* here grow together, and these are the usual natural hybrids between them. At 8,000 feet, between Buenavista and San Juan, in dense forest, the plants exist—often washed up and hidden by the trailing Lichen. Moving camp for a month or two, and lots of hard work in tree-cutting, it is possible to collect ten or twelve thousand plants, and pack them in baskets or crates so that the men can carry them out to the edge of the forest. They are then to be carried on bullocks or mules to Pacho, where wooden cases for them can be obtained, and then these are carried on mules to the Magdalena River, where they are put on board a steamboat for the coast, and shipment for England.

The infinite variety of individuals differing in size, form, and time of growth and flowering, and in the most delicate shades of colour and markings, is in *O. crispum* most remarkable, and there are hundreds of named variations in English gardens. In Belgian nurseries, as at Bruges, Mortebeke, and elsewhere, you can see this plant growing by the acre, and the eye takes in thousands of plants at a glance, all in the highest state of health and beauty. Baron

Schroeder, Mr. Thompson, Mr. Crawslay, and other private growers possess the finest of forms, and thousands are still imported by trade cultivators year by year.

It has always been a matter of regret to botanists and horticulturists that Bateman's dedication of this beautiful plant to the Princess (Alexandra) of Wales, then newly arrived in England, had to give way to Lindley's earlier name of *O. crispum*, and as the fact is insuperable, the best way out of the difficulty is to call the plant the Queen's Orchid for the future. The popular dedication of such a charming plant to H.M. The Queen is peculiarly appropriate, seeing that both came to this country at about the same time, and both have by their grace and beauty endeared themselves so much to the British people. F. W. BRIDGEE.

Imported Orchids in New Zealand.

—For many years I have been a constant reader of *GARDENING ILLUSTRATED*. I have perused many interesting accounts of rather more than ordinary experience in the culture and importation of cool-house Orchids in its columns, which have spurred me on to import for myself. In October, 1901, I received from Mexico a consignment of about fifty plants of various species, including *Laelias*, *Odontoglossums*, *Epidendrums*, *Stanhopeas*, etc. After unpacking, I allowed them to lie on very

Odontoglossum crispum.

nearly dry Sphagnum for about a fortnight. I then potted them up. Soon afterwards they commenced to grow like weeds, and in the following January one of them, *Epidendrum Brassavola*, was in full bloom. I was so surprised with the success of my first attempt at Orchid-growing that I thought I would like to let you know of my experience. Many amateurs in New Zealand, and also in Australia, will, I am sure, learn with pleasure how easy it is to establish a collection of these beautifully quaint plants. I have not had one failure; on the contrary, every plant is putting on vigorous growth. The Orchid-pan seems to suit them. I was afraid to put them on blocks or in baskets on account of the long periods of heat and consequent aridity of the atmosphere experienced in our colony. To show you the specimen that bloomed within three months after its importation from Mexico, I herewith enclose you a photograph of it. I have no doubt whatever that Orchids could be sent to New Zealand from England with equally gratifying results. Assuming this to be the case, the account of my first venture with Orchids will be interesting to growers and importers at home, as well as to the numerous amateur growers in the colonies. My plants are grown in an ordinary cool-house, no heat.—F. J. W. FRANK, Wellington, New Zealand, April 24th, 1902.

Using insecticides. I wish to point out the best way in which manufacturers' instructions are often given. I hold in my

hand a bottle of insecticide, with written instructions: "For red-spider and centipillar." "Half-a-pint of the mixture to 2 gallons of water, or three tablespoonfuls to the pint." According to Whitaker, 1 tablespoonful is 4 drachms, and forty tablespoonfuls go to the pint. Half-a-pint to 2 gallons = 1 to 32. Three tablespoonfuls to the pint = 3 to 40, or say 1 to 13, instead of 1 to 32 as before. The same errors were through all the instructions of this insecticide, and blunders of this sort are by no means confined to this particular concoction, and such blunders are most trying.—FRANK WYNNE.

TREES AND SHRUBS.

RHODODENDRONS FROM SEED.

I HAVE lately heard of a gentleman who obtained from seed a great number of *Rhododendrons*, which have flourished well in his place, which is specially adapted for them. Could I raise them in the same way, do you think, with any chance of success, as they do specially well here, and the plants are dear to buy? There were formerly, I hear, very beautiful ones here, which were removed on the death of the owner. There are still some good ones, and plenty of common ones, but I should like a variety. I have seen a lovely full yellow one, which was removed from here at that time, and I should greatly like to have one of that colour. I ordered a yellow one last autumn, and took great care of it, but it is turning out pale pink? Can you give me the name of a good yellow? Also of a full rose with darker markings which blossoms at the time (very like a *Pelargonium*)? I have a lovely pure rose-coloured one, very like an *Azalea*, which blossoms early in March, and is charming; but I should like one similar to bloom now. The one I refer to, however, has no markings whatever. I should also like the name of a very dark coral-red one, and a large white. If I tried seeds, what is the time to sow? Should I sow under glass? In what compost? Would the ripened seeds of my own be of use? If I bought seeds, where is the best place to get them? Does it take many years for seedlings to flower?—E. A. R. W.

[We do not know a hardy *Rhododendron* of the section to which you refer with full yellow blossoms. The only hardy ones at all approaching that tint is a Himalayan species, *R. campylocarpum*, whose flowers are of a primrose hue, and *R. Smithii aureum*, a hybrid kind of weak growth but with golden-yellow blossoms. It is regarded as a hybrid between a *Rhododendron* and an *Azalea*, but is very rare in cultivation, and almost impossible to obtain from nurseries. As the plants commonly known as *Azaleas* are by botanists now called *Rhododendrons*, might not the yellow one to which you refer have been an *Azalea*? A good rose-coloured variety, with a large *Pelargonium*-like blotch, is *Lady Falmouth*, but the most striking of this class is the blush tinted *Princess William of Wurtemberg*, in which all the segments are blotched with maroon. Of self pinks without spotting, a delightful flower (which was very much in evidence at the recent Temple Show) is *Pink Pearl*, but it is still quoted at a high price. Another good self pink variety is *Sylph*. Of dark reds, either *Ascot Brilliant* or *Atroroseum* would suit you. *Helena Schitner* is a good white. There is no reason why you should not raise seedlings yourself, and you may also obtain your own crosses. To do this it is simply necessary to transfer the pollen from one flower to the stigma of another. You will find it necessary to wait for a day or two after the flower has expanded before the pollen has developed sufficiently to be removed, and about the same space of time is needed for the stigma to acquire its glutinous character. Whether the flowers are artificially fertilised, or set of their own accord, or by insect agency, the results are the same—that is, the flower drops and the seed-pod commences to swell. It ripens, as a rule, towards the end of the summer, and when you suspect it is near that stage a sharp look-out must be kept, as the pods often burst with but little warning, and when this happens the seed, from its minute character, is blown away and lost. Two courses are open in dealing with seed-pods when nearly ready to burst, the first being to pick them and place in a dry sunny spot, and the second to enclose them in a piece of fine gauze, so that when they burst the seed is retained. This last has one advantage, as by so doing there is no danger of picking before the seed is fully matured. The seed may be sown at once or kept till the following spring, but being so minute it is a good plan to sow as soon as possible. When very large quantities are grown seed is often sown in beds, but in your

case the better way will be to sow it under glass. It will only need the protection of an ordinary garden frame, as the principal object of the glass protection is to maintain an even state of moisture. Clean, well-drained pans are very suitable for sowing the seed, the drainage being supplied by a layer of broken crocks in the bottom of each pan. Then take some good sandy peat (if necessary mix some silver-sand with it), and pass it through a sieve with a $\frac{1}{4}$ -inch mesh. The rough portions that will not go through the sieve should be laid over the crocks in the pan, on which place the sifted soil, which must be pressed down firmly and level. On this sow the seed, not too thick, and cover with a slight sprinkling of the same soil sifted much finer. All that is necessary is to place in a frame, water when necessary, and keep fairly close and shaded from the sun. The seed will come up in the course of the summer, and when the young plants get crowded they must be transplanted into other pans, using the same kind of soil and prepared in the same way. In any watering of the seed-pans or minute plants a fine rose is very necessary. The next shift may be out-of-doors, for which you require a nice moist peaty spot, in which they will soon become established. Your own seed will probably be more satisfactory than any you can buy. It will take five years at least for the seedlings to flower so that their merits can be properly determined.

P. S.—Since the above was written we have been looking over a large collection of Rhododendrons, and the finest of all the kinds with flowers spotted like a Pelargonium was Sappho, a bluish-tinted bloom with a blackish-maroon blotch.]

Oytisus Adamsi.—I have in my garden a Laburnum which bears both pink and yellow blossoms, specimens of which I am sending you with this. The tree has very little foliage, and on several branches the bloom has both colours on one spray. It is growing in a border with red and pink Hawthorn and pale yellow Laburnum. Kindly give me any information in your power as to the cause of this in one of the earliest numbers of your journal, and oblige—X. Y. Z. and Inquirax.

[The flowers sent are of this very curious Laburnum. It is supposed to have originated by grafting the purple Oytisus purpureus upon the common Laburnum, a graft hybrid being the result.]

FRUIT.

CHERRY GUIGNE D'ANNONAY.

This fine small Cherry was raised in 1860 by M. Al. Jacquement and Bonnefont, Annonay, and named Guigne marbrée précoce. The fruit is regularly heart-shaped, bright red, changing to dark purple, flesh very tender, juicy, sweet, and of excellent quality. It ripens in the open air early in June. It does well in pots, as also in the open air, trees on walls growing and bearing freely. The fruit also sets well, on some trees we lately saw the fruit hanging in large clusters. It is certainly the earliest Cherry we have, and on this account, and also its many good qualities, it deserves extended cultivation.

PEACH STONES SPLITTING.

I HAVE twenty-four trees of Amsden June Peach, and about one-third of the fruit has got split stones. Would you kindly tell me the cause of the stones splitting so much? I have enclosed fruit, hoping you will be able to tell me what will stop the splitting for next year.—W. P.

[Some kinds of Peaches are more addicted to stone-splitting than others, though it happens sometimes in a variety not commonly given to that falling. To imperfect fertilisation of the flowers may be traced the origin of some such cases, and where this is so there is no remedy that can be applied that will benefit the present crop. The vigour of the tree affects the quality

of the difficulty, because stone splitting is not an outcome of indifferent health; indeed, the reverse is more likely to be the case. When Peaches are flowering it is never safe to trust to chance in the setting, for without being fertilised with their own pollen or with that of other flowers by the aid of a camel's-hair pencil, rabbit's tail, or something of a similar character, the fruit may swell away for a while, even to ripening, and then drop from premature softening accelerated by the unsound stone. In this condition the fruit sometimes falls and appears ripe, but an examination shows that it is soft only on one side, the other being congested and hard. It is among the early sorts that these troubles most frequently occur.

In too rich borders some Peaches drop when nearing the ripening period, and if they remain

An early Cherry, Guigne d'Annonay, growing in a pot in the gardens at Gunnersbury House.

until they can be gathered they invariably ripen some time before the remainder of the crop is ready, which the expert grower at once recognises as a symptom of stone-splitting. Freshly slacked lime applied in quantity sufficient to whiten the surface is a good remedy in such cases, giving it once or twice during the growing season. With trees that are over-luxuriant, root-pruning, lifting, and placing the roots nearer the surface correct more than the one evil, bringing with it the lessened tendencies to splitting of the stone. Overhead shade from other trees hinders proper ripening of the wood, and without this neither perfect setting nor stoning can be assured. Excesses of root moisture or drought are both inimical to the progress of the tree's growth in summer, and should be as far as possible avoided, as also should strong doses of animal or artificial manure, because they stimulate an excess of vigour which is undesirable. With the com-

monly new border and healthy trees clear wood is all-sufficient. It is for older trees in borders fully occupied with roots and carrying heavy loads that feeding is necessary. Lime, however, may be given in small quantity with advantage to Peaches, as this assists the formation of the seed-shell or stone. Unripe wood caused from overhead shade, imperfect fertilisation of the flowers, or a absence of lime in sufficient quantity may, however, give the clue for the failure complained of, and for two of them, at any rate, steps may be immediately taken to correct it for another year. Carefully lifting the trees and replanting will correct grossness, the autumn, when the leaves begin to fall, being the most suitable time. Another take that is often made is neglecting the watering of the borders and syringing of the trees after the crop is cleared.]

NOTES AND REPLIES

Black Currants failing.—Can you say how Black Currant bushes blossom well, and just as the fruit is about to set the bunches wither off? These bushes have done this for three years in succession. There are no long rows between Raspberries and Gooseberries which both fruit well. The bushes have plenty of young wood, plenty of young wood, the old being cut out. They are very healthy, and get an annual mulch of stable-manure. The soil is very good and moist.—A. L. L.

[Your Black Currant bushes are overrun with green-fly, and there is far too much old wood in them according to the samples sent. Cut out all the old wood from the base of the bushes and allow the young wood to take its place. Black Currants bear on the wood formed the previous year, and that sent is in some cases two and three years old.]

Thinning Apples and Pears.—The great wealth of blossom on these trees gives hopes of well-filled fruit stores, but whether the hope will be realised remains to be seen. Some trees are regular in their bearing, others give biennial crops. These are the trees that need thinning of their fruits, for when such heavy crops are carried the trees become so severely taxed that a year's rest is necessary to recover their lost energy. On large trees, such as orchard standards, or in large or small gardens where labour is scarce, fruit thinning often goes unheeded. Advice in such matters is none the less valuable because of this, for while there are some who cannot give this attention to their trees, there are others who would do so if they were reminded that such a work was remunerative. Finer fruits individually and greater regularity of crop would be more universal were thinning of crowded fruits carried out in early summer. This applies to all choices, such as well as Apples and Pears. The frost, however, and cold winds of the past spring have in many a case told against bounteous crops on open-air trees, and some even on walls, but little better. Trees of a stature allowed for this thinning of the fruit should be given this attention where it is practicable. Thinning both of Apples and Pears applies to all kinds, though the larger-fruited kinds are those which probably repay the better for it. Much good may be done as regards the late Codlin or summer and autumn Apples, gathering a portion of the crop for early use, and the earlier this is carried out, once they have attained to suitable size, the better. W. S.

VEGETABLES.

AUTUMN GIANT CAULIFLOWER.

A WRITER in a daily paper told its readers late as May 23rd to sow Autumn Giant Cauliflower seed to secure September cutting. Were such advice adopted few heads would be ready for cutting from plants so raised earlier than Christmas. Really, those who sow September Cauliflowers should already have strong plants to put out now, for it is essential to have good heads then, that the plants become strong ere hot, dry weather sets in. Cauliflowers for early cutting can hardly be well done, as plants that have free growth and luxuriant leafage heart in the earliest. Early cutters of these vegetables during August, when fine white heads form a strong feature in the collection, usually sow seed under glass early in March, and thus have strong plants to put out early in May. A sowing made in a similar way, but in a cold-frame or under a hand-

GARDEN WORK.

Conservatory.—Rearrange often, and remove all non-effective plants to other houses. Make the most of the best specimens by placing in conspicuous positions—elevated, if necessary. *Rhynchospermum jasmoides* is a sweet thing when well done. It will flower early in the stove, later in the conservatory, and I have seen it growing against a warm wall in the south. But it is happiest under glass in an intermediate temperature, where it soon makes a good specimen on a globular or any other shaped trellis. If the climbers are well selected and kept within bounds they will be both useful and beautiful now. *Lapagerias* want a bed of peat well-drained, in a cool house in a shady position. The same position will suit *Clianthus puniceus*, which is subject to red-spit if exposed to hot sunshine where the syringe cannot be used freely. I have occasionally seen this plant well done in rather small pots, and it is then very novel and attractive. *Cantua dependens* is another rather uncommon plant which, when well done, leaves a feeling of satisfaction with the grower. Let the plant make its growth in the intermediate-house and ripen in a lower temperature. Roses planted out under glass are rather difficult to keep clean in a mixed collection. The vaporiser will kill all insects belonging to the aphid tribe, but there are often difficulties in the way of vaporising large houses, especially if joined to the dwelling-house. Therefore, it is generally necessary in the case of Roses to use washes or dry powders for the destruction of insects. I prefer Tobacco-powder, where it can be conveniently used. Green-fly very frequently is in the hearts of Trumpet and other Lilies, surrounding the embryo flower-buds. Where washes cannot penetrate a little Tobacco-powder dropped in among the foliage effectually settles flies without doing any harm to the flower-buds, but the important thing is to be in time, and next day to wash it out with the dead with the syringe. See that plants growing in the borders are well supplied with water. All plants in bud, and when the flowers are expanding, will benefit from liquid-manure. But liquid-manure should not be given to plants when the halls are very dry, as it is a wasteful method.

Stove.—In most gardens a few *Oreobids* are grown, and the time to place in now baskets or to repot is just as they are starting into growth. Even when plants are doing well, it is well to overhaul them. See to the drainage. Pick away some of the old soil or dead roots, if any, and make up with fibrous peat and Sphagnum Moss, the latter chopped fine. A few bits of charcoal help to keep the mass sweet. Though *Orchids* require a very open compost it should be pressed in firmly. The roots are strong enough to force their way through a close mass, if only it is composed of fibrous materials, and besides, the Sphagnum and the peat compressed retain the moisture long enough to nourish the roots till a further supply is given. What *Orchids* dislike is a close pasty mass of inert stuff into which the roots will not enter. Light shade must be used when the sun is bright, but remove it as early as possible in the afternoon when the sun has lost its power of doing injury. If the house is not too heavily shaded it is not easy to have the atmosphere too humid inside during the season of growth in bright weather. We cannot altogether do without fire-heat at night, but when the thermometer will remain above 60 degs. all night fire-heat is not required.

Young Grape-Vines.—June is a good month for planting young Vines propagated the same season. If raised on turves the turves can be moved entire as soon as the roots are working through the sides and placed in the border, surrounded with good soil and watered with warm water to settle them in position. It may be necessary to shade lightly for a few days till the roots get to work. When that is evident remove the shade and maintain a moist growing atmosphere, and by the end of the summer the young Vines will have reached the top, and if not stopped will be half-way down the other side. I have seen a crop of Grapes taken the following season when money-making regard-

less of the Vines was the object, but in the long run it does not pay. Better cut the Vines back when the leaves are ripe, and take up a strong cane next season. This would not prevent one bunch being taken the following season to prove the varieties. Those who want quality will plant *Hamburga* and *Muscate*; those who prefer bulk and weight will grow *Alicante* and *Gros Colman*. To get the growth of young Vines made early, warmth and moisture are necessary. It is wonderful what a stimulating effect a bed of gently fermenting leaves has upon the growth of young Vines.

Exposing Peaches to the sunshine.

—When thinning Peaches and Nectarines, as far as possible leave the fruits on the upper side of the trellis, or if the trees are in pots then have the fruits exposed to strong light by keeping the trees and their wood reasonably thin and uncrowded. I believe there is money in Rivers' Nectarine if a house or houses can be given up to it. A friend of ours grows good crops in pots, and afterwards fills the house with *Chrysanthemums*. There is not so much profit in *Chrysanthemums* as there was a few years ago; not that there is any falling-off in the demand for cut-flowers, but the number of growers is steadily increasing and the price comes down, except it may be for a few special kinds.

Feeding Tomatoes.—There are various ways of doing this, the cheapest, and, I think, the best, is to raulch as soon as the bottom trusses are set with good manure from the stables or elsewhere.

Window gardening.—Tuberous *Begonias* are coming on now, but the *Pelargoniums* will soon be going out, and will then, of course, be placed outside. Any plants not contributing something to the general effect may now be placed outside. Double and single *Petunias* are bright, but are soon drawn up weakly. The best window plant is the Ivy-leaved *Geranium*, and windows filled with a good collection of the best Ivy *Geraniums* would be very attractive.

Outdoor garden.—This is a late season, but since the wind veered round to the south and the warm air circulated, vegetation has moved rapidly. The bedding-out is now finished, even the sub-tropical plants are in their allotted places. *Cannas*, especially the dwarf large-flowered varieties, are lovely plants, but they must have good soil and a sheltered position. The Tuberous *Begonia* is making headway, but it has not yet ousted the *Geranium*—probably never will, as the *Geranium* will flower freely under difficult conditions, and the *Begonia* will not. At any rate, there has been a very large run on scarlet *Geraniums*. There has always been, and I expect always will be, a craving for brightness in the garden in our climate. Though there may be brightness in the garden without *Geraniums* or *Calceolarias*, *Panicles*, *Carnations*, *Roses*, *Pinks*, and many other plants, if only brought back to the garden in sufficient numbers, will give us colour enough and yield abundance of long-stalked flowers for cutting. *Pyrethrums*, both single and double, are lovely now. A patch of *Anchusa italica*, with its tall, slender stems loaded with sky-blue flowers, attracts attention, though the flowers are not lasting enough for cutting. The German *Iris* will do because the buds open in water. *Violas* and the large-flowered *Pansies* were never brighter with us than they are at this moment, and one regrets the necessity for their removal to make room for the summer flowers. Any plants which require stakes should have attention. Guard the *Dahlias* from slugs.

Fruit garden.—The lesson that everyone learns ament fruit culture sooner or later is never keep old trees. It is possible to improve old trees if not too far gone by rich top-dressings, but when all is done, the young trees from eight or nine up to twenty years old pay the best, and if on the Paradise stock on an average soil no tree will pay for its keep at the end of twenty years, and may require replacing earlier. Another matter that forces itself upon one's attention is never plant a young tree of the same kind on the site from which an old tree has been removed without changing a good proportion of the soil and

Capital plants to put out now for if still another sowing be made sows, then should there be from to put out where to remain in July, from heads during November and These last may well follow after Potatoes, or other early crops, the merely pointed or deeply hood over-planting, but not otherwise disturbed. late cutting large plants and heads desirable; also, such plants are hardier those grown more freely and gross. It to over-estimate the importance in men of a good supply of autumn Cauli- Late in the year and after the heat of is over caterpillars give little trouble, are they are seen a washing from a can slightly brackish or salt water often to cleanse them of these pests. To keep beds white and firm it is well, so soon as the partly formed, to break down a few of the leaves over them, and thus protect sunshine or storm. A. D.

NOTES AND REPLIES.

Asparagus and other Kales.—Were I to name the very best Kale for late sowing, I should say Asparagus Kale. In my opinion like the past one, late Kales or have been most valuable, seeing the Cabbage is late in coming in. Where a large supply of vegetables is needed, then it is always safe if he has a patch of purple Broccoli or Asparagus Kale. This may be had well into June. I prefer it to Cabbage from a flavour point of view. Asparagus Kale is of the simplest culture. It is in the early part of June, and plant out during the first half of August, 18 inches each way. In this way it does not suffer from frost damage, from the stumps not being too large and coarse. The old Ragged Jack is still a tender and highly flavoured Kale. For those who are in very exposed places and want a very hardy kind and do not mind the colour, the Delaware is to be recommended. I have never seen it killed, and it is a most profitable and very tender.—J. CROOK.

Cucumbers.—Where it is desired to plant Cucumbers in frames arrangements will very soon have to be made for their reception. It is, however, advisable not to be in too great a hurry, as it is wiser to wait a little rather than risk should be run. I have seen healthy Cucumbers plants got into frames out-of-doors—houses where almost unlimited heat could be had on—the first week in May, and when the soil of the bed had subsided and cold nights had they were entirely crippled. From the middle to the end of May is, as a general rule, the best time for frame Cucumbers, as by that time the sun has greater power. Many, in company with myself, do not attempt to use the frames in this way before the end of the month, when it is that they are cleared of bedding, etc., and if planted then one may experience cutting fruit in July, more particularly if the frames, as they should be, are placed in a south aspect. There are other ways of growing Cucumbers without utilising frames or devoting a house entirely to them. I have seen the planting of them in boxes and pots in houses where mixed collections of plants are raised. It is, I am aware, generally believed that the most of necessity devote a house exclusively to their culture, keeping the place very warm, humid state. This, of course, is a capital whera fruit is wanted to be cut freely, but as there are very many who cannot do this, because they only require to grow for their own consumption, and have to grow a mixed collection of plants, it will be found that if they are planted in large boxes or small beds of fermenting material, the plants kept as far away as possible from the sides of ventilators, useful fruit may be obtained throughout the season. This has been my experience, and those who cannot make it convenient to plant either in frames or give up a house to Cucumbers will find this mode the best answer.—TOWNSMAN.

As many of the most interesting notes and replies in "GARDENING" from the very beginning have been from its readers, we offer each week a copy of the volume of either "STOVE and GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue which will be marked.

clearing out every bit of old root which might in the autumn form a store-house for fungus. There is likely to be a good crop of Apples from what I see of the trees near me, but only a sprinkling of Plums and other fruits. Early Strawberries suffered from the frost. Most of the early blossoms in sunny positions were blackened by the frost, but the later trusses have come up well. Peaches and Apricots should be thinned where the crop is heavy. Plums, Pears, and Apples, where the trees are of a manageable size, should have all the small and deformed fruits removed. It is of no use leaving the deformed fruits on trees, even when the crop is likely to be a light one.

Vegetable garden.—A dripping June, according to the old adage, puts things in tune. It gives an opportunity of getting out the winter greens and Celery without much watering, swells out the Peas, and gives a crispness and flavour to Lettuces and other salad plants and Cauliflowers that are absent in dry, hot weather. It is true there are drawbacks: the weeds are getting troublesome, especially when the hoe is laid aside for a time when the bedding-out is in operation, but we wanted the rain and were glad to see it. In staking Peas do not crowd the lines of sticks too closely together at the top. Give the Peas a chance to remain inside the sticks and they will do better. Neither is it wise to have the rows too near each other. Isolate the late Peas especially, and they will bear better, and there will be less mihew. The presence of mihew is owing to a check from drought, and a shallow, badly-worked soil, and possibly also in some cases to thick sowing. The other day I saw a man sowing Canadian Wonder Beans, and when I remarked he was putting them in thick, he said he could thin them. But why waste the seeds? If the thinning is delayed the crop is injured. French Beans should not be nearer to each other than 6 inches. This gives them a chance for full development to bear a full crop, and when the Beans are gathered frequently there is a constant succession. Tomatoes in cool-house will require frequent attention. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 23rd.—Have discontinued cutting Asparagus, except it may be a stray haul or two for some special occasion; shall feed as much as possible for a month or so now. We are trying to fetch up arrears of work, as during bedding-out other work stands still. The turf on the lawns has been benefited by a light top-dressing of basic slag and nitrate of soda, and the Grass grows very fast. Second early Peas will only be sown now. Huntingtonian has been a favourite for succeeding the late Marrows.

June 24th.—Finished potting specimen Chrysanthemums. We do not shift into large pots until the roots have filled the previous pots, for the sake of getting the work done by any special time. Pricked off Cinerarias and Primulas. Liquid manure is given to Roses in dry positions, and the surface has been mulched with manure, the latter being covered afterwards with soil and pressed down to keep the birds from pulling it about. Runners of Strawberries are being looked after.

June 25th.—Moved a few of the hardiest Palms from the conservatory to sheltered positions on lawn. Orange-trees in tubs are also placed outside. This annual outing does them good. The creepers have been regulated and a few plants brought from the stove to ease matters there. Camellias in pots have been placed on a cool-shaded in a shady spot. Rhododendrons, Dentinas, and other plants which have been forced have been placed outside to ripen and rest ready for next season.

June 26th.—Planted more Broccoli and winter greens. I believe in early planting on very soil. Top-dressed Cucumbers in houses. Very little air is given and only the lightest possible shading, as if the plants are right at the roots they will stand a little sunshine. As soon as a Cucumber plant drops its leaves in every gleam of sunshine it is time to pull it up and replant. They are tall ones.

fight on some Peach-trees, and Tobacco-powder is still in use.

June 27th.—Thinned various kinds of fruit on wall trees. Fishing-nets only are used, and are not much trouble nor yet much expense, as we should have to keep nets for covering fruit-trees and Strawberries. Of course, they wear out and have to be replaced, but the annual cost is not much. As Pelargoniums go out of flower they are placed outside in the sunshine to ripen growth ready for cutting down. Air is left on all night on most of the plant and fruit-houses.

June 28th.—Good fruit of Early Rivers Nectarine has been gathered from pots in cool orchard-houses. This is a valuable kind. Attention is being given to the pricking out of hilly plants sown in boxes in cold-frames. Weeds have given a lot of trouble. This puzzles us somewhat. So far as is possible no weed is permitted to seed, yet every season a crop comes up. Seeds are scattered by the wind. Shifted on Zonal Geraniums for flowering in winter. Sowed more Lettuces.

LAW AND CUSTOM.

A garden fence.—The fence between my garden and my neighbour's garden consists of about 34 feet of White Thorn and Privet, growing on the top of a bank some 24 feet high, making a total height of 6 feet. My neighbour wants me to cut the fence down to 34 feet in height, but I am not willing. Can he do this on giving me notice? The hedge is a party hedge. Is there any legal limit to a hedge between gardens?—S.WANSEA.

[There is no legal limit to the height of either a party fence or a boundary fence (of live or growing wood) between gardens. You say this is a party fence, but are you correct? Or do you mean that it is a boundary fence dividing the gardens? If it belongs to you your neighbour cannot touch it, no matter how high it may grow, so long as it does not naturally overhang his ground.—K. C. T.]

The Market Gardeners' Compensation Act.—I took a lease of this house and garden as a private tenant. I have since gone in for raising flowers for sale, and, as I contemplate erecting more glass, I wish to come under the Market Gardeners' Act. Will the landlord's sanction in writing be sufficient? Or must I get the lease endorsed? 2. Does the Act lay down any definite scheme of compensation for improvement (at the expiration of the tenancy)? And, if so, what? Or does it merely enact that the whole matter of compensation shall be referred to arbitration?—BROWNE.

[1. If you obtain the written consent of your landlord previous to commencing to erect the glass-houses it will scarcely be sufficient, as the holding is not cultivated as a market-garden. To raise flowers for sale is not to cultivate a market-garden. You should get from your landlord written permission to erect glass-houses and to remove them on the termination of your tenancy. It would be well to have this permission endorsed on your lease, although this is not strictly necessary. 2. The Act does not prescribe any specific compensation—the measure of compensation is to be the value of the improvement to an incoming tenant of the holding, and if the landlord and tenant do not agree as to this, the difference between them is to be referred to arbitration. For the reasons already given, I think your holding is not one to which the Act applies.—K. C. T.]

United Horticultural Benefit and Provident Society.—The monthly committee meeting of this society was held at the Caledonian Hotel, Aisleby-terrace, Strand, on Monday, 19th inst., Mr. C. H. Curtis in the chair. The minutes of the last meeting were read and signed. Four new members were elected, making a total of fifty-seven this year. The death certificate of the late Mr. J. N. Forbes was produced, and the amount standing to his credit in the ledger (£4 1s. 6d.) was directed to be paid to his nominee. Three members were reported on the Sick Fund. The amount of sick pay for the month was £9 12s.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. J. Soloy, Netherleigh, Tibberton Road, Great Malvern, for Cistus Jenkinsii grown in a window; 2, Mrs. T. Norman, Holly Hill, Ditchingham, Norfolk.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Pall Mall-street, Holborn, London, E.C. Letters on business should be sent to the PRINTER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being variegated and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Silene pendula (Hugh).—This is the name of the flower you send. There are several varieties of this fine biennial. The compact varieties, which form compact, rounded heads 6 to 8 inches high, are mostly used for spring bedding. To obtain good plants for spring sowing, seed should be sown in the reserve garden in autumn, afterwards transplanting the seedlings to permanent beds. Flowers appear from May to August, according to the season of sowing.

Iris not opening (Constant Reader).—The failure of the Iris flowers to open is due, no doubt, to the want of roots, those on the piece you send having perished. We would advise you to lift the plants, clearing out the soil, in which there seems to be too much manure in contact with the roots, and replant in good loamy soil, to which all has been added some sand if it is very heavy. Cut off all the decayed pieces of the old plants. See reply to "Joumal" in our last issue, page 215.

Prolonging the bloom of Fuchsias (M. C. L.).—When they become somewhat tall, and, as they frequently happens in the south, infested with insects, it is a good plan to cut them close down; when this is done, especially if they get a good watering where needed and a top-dressing of some good rotten manure, they soon push up strong, clean shoots, and flower again abundantly. In some southern gardens this practice is repeated with success several times during the season.

Raising Phyllocactuses (John Allan).—In a good sunny spot your Phyllocactus pods should soon ripen, and when this stage is reached they quickly begin to shrivel and it is then a good time to gather them. As you have not many, the better way will be to open them and pick out the seeds, which should be sown in clean, well-ventilated pans in a mixture of loam, leaf-mould, brick rubble, and silver sand. When sown, they should be covered to the depth of a quarter of an inch with some of the same material sifted fine, and then placed in the warmest part of the greenhouse, or even warmer, if you have such a structure. The soil should be kept moist, but, of course, overwatering must be guarded against. When large enough, the young plants must be potted singly into small pots, using the same kind of compost, and afterwards shifted into larger pots as they require it.

Alpine Auriculas (Woodroff).—Practically any of the large number of Alpine Auriculas in commerce should do very well outdoors in suitable soil on a moderately shaded border, and where the plants are mulched with fine loam, leaf-mould, brick rubble, and silver sand, and highly protected from frost, snow, and heavy rains in the winter, and especially whilst in bloom. But it would not be possible to name a few as better to this purpose than others, for the reason that most of them are grown in pots under glass, though cool, and real test of hardiness is thus not applied. Much depends on what you may regard as an alpine, for all hardy border varieties, few of which are named and are easily raised by the amateur from seeds, are alpine, too, but are not florists' named alpine. Either you should purchase from a florist strong plants of border varieties in pots, or else purchase a packet of seed and sow at once, and thus raise scores of plants.

Laced Pinks (Woodroff, Snickett).—One of the best coloured laced Pinks is Derby Bay, pink ground, with bright red edge. Bolard is one of the finest heavy laced white grounds. Mrs. Darke (claret-red edge), Barry Hooper (reddish-purple edge), Favourite (rosy-red edge), and Lady Claren (red edge) make up a capital selection. As to hardiness, Pinks vary in places, something depending on whether position be high or low, dry or humid, also as to nature of soil, as the Pink which likes plenty of excess of peat, (in the soil, as the Pink which likes plenty of mortar sittings, are all injurious to Pinks, especially near towns. A planting in a piece of young shoot about 3 inches long, pinched out, then inserted into sandy soil as cutting. A cutting is a similar shoot cut off with a knife, but a little longer, the base close beneath a leaf joint, and two or three of the lower leaves cut off. The time for propagation is just as bloom is going off. Set with small stick into sandy soil under a north wall, and cover with handlight.

Violets not flowering (H. Edwards).—You do not say what variety you refer to, and, as there is a great difference. Princess of Wales, for example, is very shy flowering, and La France in some districts is inclined to the same way, but in some is not. Violet plants at 4s. per dozen should be full of flower-buds, but the plants will not flower after themselves year by year, even though the 4s. price was paid for them. It is only by annual propagation that good flowering clumps are obtained each year, as when we speak of propagation we have in mind the cutting system, as opposed to rudely pulling another year's

plants as are well high worn out by a prolonged flowering. The best and freest types of Viola for winter and early spring flowering are those belonging to Marie Louise, Vespadina, Victoria, etc. You give no idea of the condition your plants are in, but at this season we can only urge you to match them with short manure, and so obtain a good growth for affording runners in the early autumn for propagation. The latter subject is hardly reasonable now, but it is so important a matter, and so many of our correspondents laid with their Violas, that we shall in due course deal with the subject fully. If you possess the single variety Princess of Wales, and find after treatment that it will not flower, you had best discard it.

FRUIT.

Warts on Vine leaves (Seely Park and E. W.). The warts with which the Vine-leaves are affected are only small green excrescences that form on the backs of the foliage, a sort of extravasation of the sap through the leaf. They hurt the leaves, no doubt, as affecting respiration, and are the result of some ill health in the Vine. The trouble is often caused by a too close, warm atmosphere, saturated with moisture, and Vines badly affected take a long time to recover.

Injured Vine-leaves (Gros Colman).—There is very indication that your Vines have grown well, if the leaf you send is a sample of the whole. Its condition, however, when it reached us was such that it afforded but little clue to the cause of your trouble. As far as we can judge, the injury to the foliage comes from the scald, probably accentuated by some atmospheric influence. Some growers damp the floors of glass-houses with liquid-manure, diluted so as to give off ammoniacal vapours, which are by many Grape-growers considered favourable for leaf absorption. We have proved this season that this needs care, otherwise injury may follow. This is more likely to happen if, after the ventilators have remained closed for some hours, the inmates are exposed to sunshine without ample provision for the escape of these gases, bottled up, so to speak, during the hours of confinement. Sulphur on the hot-water pipes, too, has a similar effect on Vines should the pipes be well heated and the air of the house remain unchanched before sunrise, or, rather, before it touches the house. If these prove the cause in your case, the remedy will be obvious—namely, closer attention to morning ventilation. It is "catchy" weather it is not wise to close down the ventilators while there is a prospect of an alternating with cloud.

VEGETABLES.

Cesspool contents for a garden (Inyornanus).—In summer, such crops as Cauliflowers, Calabages, Peas, Broccolis, Scarlet Runners, etc., will take with advantage a good deal of diluted sewage, such as you refer to. It is also useful for Strawberry-beds from about the middle of April until the fruit has set, and in the winter pour it over the roots of fruit trees, including Currants, Raspberries, etc. It will be found valuable for Asparagus-beds after cutting has ceased, giving it well diluted.

Feeding Asparagus (M. C. L.).—The feeding of Asparagus should begin immediately the cutting is stopped. This may be met by occasional soakings of liquid-manure or by sprinkling at the rate of 2 oz. to the square yard of superphosphate and salt. This manure means to suit the Asparagus well; indeed, there are few crops it does not suit. The better the stems of the Asparagus are nourished the finer the produce will be next season, and where growing in a very exposed place in any position where the stems are likely to fall about these should be supported in some way. A few Pea stakes thrust into the bed at the time cutting is relinquished for the season is a good protection, and a stout stake at intervals of 8 feet, with a line of tar string all round, is an excellent support. Seed-bearing is weakening, and if time can be spared a little of this should be renewed by taking the side branches off with a knife. Anything, in short, that can be done now to ease the plants and enrich the beds where they are growing will be well repaid by the increased size and earliness of the crop next season.

SHORT REPLIES.

Peter.—The only way to clear your greenhouse of green-fly is to fumigate it.—Seddon.—In such a house as yours it is impossible to have any plants in flower during the summer, with the exception of a few late-flowering Chrysanthemums. You must in the autumn, put up Hyacinths, Tulips, etc., which will come in in the early spring.—White Pink.—Yes, they can be left in the ground, but we doubt very much if you will get much bloom next year. It is far better to lift them, dry them off, and replant early in the autumn, and even then the early-flowering Tulips will not bloom so well as newly-purchased bulbs.—W. Fred.—We know of no cheap book dealing with the subject you refer to.—R. A. P.—1, You have done quite right. The Acazia will very likely root, and thus be on its own roots in time. 2, You need not trouble about the Acazia. This splitting is common. You will find a number of suckers spring from the bottom of the stem which has flowered, and very likely the flowering stem will form two heads.—Miss H. Hobbs.—The only thing you can do is to syringe them with some insecticide.—S. Lytle.—Your letter was attended to, and an answer was given in our issue of May 3, p. 136, under the heading "Names of plants."—H. Temper.—Yes, it is, as far as we can judge, the branch of a Pear, but what variety is possible to say without fruit.—S. H. L.—In all probability the wood is too thick. You ought to cut out all the wood that has flowered, and thus allow plenty of room for the young growth that is formed.—R. L.—Not a gardening query. Your best plan will be to consult a solicitor.—A. Rejoice Reader for Many Years.—You cannot do better than make a hedge of Yew. Jolly would have been better, but you object to any plant that has prickles.—Arthur P. Davison.—See reply to Mrs. Moore Dyke, in our issue of June 14, p. 211, re "Clematis dropping."—Sturm.—See reply to "S. J. A." re "Peach-trees casting their fruit," in our issue of June 14, p. 210.—F. W. Daria.—No doubt the result of the cold, unreasonable weather we are having. With warmer days and nights the flowers will come all right.—J. A. P.—Any of the Londonallydianes would answer.—Pink.—The Carnation you refer to will break from the bottom in due course. If you do not want it to flower, pluck out the

point, and thus encourage the plant to break away.—St. Asaph.—Apply to Mr. J. Pinches, 3, Crown-buildings, Crown-street, Camberwell, S.E.—Inquirer.—Your Rose is the old China.—Amateur.—Sow your Forget-me-not at once. Godetia is not hardy, and this you must sow in the early spring—say, April. You could sow a pinch of Godetia now, and, if the autumn was fine, it would come into bloom late.—A. H. P. M.—1, The plants that rabbits will not eat are very few in fact, there are none that they will not attack. 2, Apply to Messrs. Morgan and Thompson, Ipswich.—A. M. D.—1, Please send some specimens of the shoots of the Chrysanthemums to which you refer, and then we will be better able to assist you. 2, Yes, anis are injurious in the garden. 3, The only thing you can do is to syringe the Roses often with some well tried insecticide.—Jus. J. Pilling.—Keep the sawdust-mixture out of the garden, as it will only breed fungus, and is of no value whatever.—Jack.—The pot is all right. No doubt it was dirty when you potted up your plants, hence the trouble.—R. B.—Your Grapes are what is known as "scabbed." See note in our issue of June 7, p. 198.—Veece.—If you want fine-folaged plants, any of the small Palms, Dracaenas, Aspidistra, Ficus, Ferns, and Asparagus. If flowering plants, try Fuchsia, Pelargonium (Zonal), Hydrangeas, Begonias, Cactus, with, in the early spring, Primulas (Chinese), Hyacinths, Tulips, and Daffodils in pots.—E. H.—See reply to "Seely Park," re "Warts on Vine-leaves." We can find no traces of red-spider on the leaves you send.—F. B. B.—Your Peach-trees are suffering from what is known as "hister." See reply to "Major," in our issue of May 17, p. 164.—Jarkob's.—Lift the Aubrietia, pull it to pieces, and plant in the reserve garden. It will come in well for planting out in the autumn to flower next spring.—F. Thomas.—We have never heard of Horseradish being used in the way you suggest.—Carlo, Chorley.—We fear the only remedy is the one you suggest, as it takes a long time for the material you speak of to soak into the wood.—F. N. Hortley.—Tilted Pansies can be grown successfully when the garden soil has been treated to a liberal dressing of really good animal manure. From the nature of your query, we are at a loss to understand whether your garden soil is deficient in this respect. Any of the artificial manures applied carefully will assist the growth considerably.—Fred Bateson.—Dne, no doubt, to the unseasonable weather we are having.—Alf Pamphillia.—The only thing you can do is to wait and see if you get any fruit.—K. E.—See reply to "J. W. T." re "Renaking Lily of the Valley bed," in our issue of May 31, p. 185.—E. Simmer (S. C. R.).—See reply to "S. C. R.," in our issue of June 7, p. 197, re "Trespassing cats."—Stefano.—The recipe we gave was 1 peck of lime,

1 peck of soot, 6 lb of sulphur, boiled together for two hours; when cool, use 4 pint to 4 gallons of water (preferably soft water). Other query next week.—J. D.—Quite impossible to assign a reason without further information.—Chilton Rectory.—Your gardener is quite right. It is next to impossible to clear out mealy-bug, unless by burning the heavily-infested plants, and then continually washing those left with some insecticide. You must thoroughly repaint the house as well.—Mrs. H. Hulton.—In your district you had better plant Ceanothus Veitchianus against a wall, and even then it will need slight protection in the winter.

NAMES OF PLANTS AND FRUITS.

** Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, Finsbury-street, Holborn, London, E.C. A number should also be fruitfully affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time. Names of plants.—K. K. D.—1, Staphylea colchica; 2, Send when in bloom.—P. L. Smith.—1, Poppy Anemone, single form; 2, Saxifraga cespitosa; 3, Arabis alliiata; 4, Send in flower.—W. Lewis.—1, The Throatwort (Trachelium coruleum); 2, Petris sp., please send fertile fronds; 3, Cyperus alternifolius; 4, Adiantum punctatum.—G. M. D.—Staphylea colchica.—J. P. T.—1, Arthlasarthes (Trassula) rosea.—Crafton.—1, Arthlasarthes (Trassula) rosea; 2, Helianthemum vulgare; 3, Phlox thurkiana; 4, Baptisae Caeonium.—Inquirer.—Quite impossible to name from such poor, badly-packed specimens.—M. E. Nolle.—Polygonum historica.—Co. Cook.—Double Rhododendron ponticum.—J. W. Merle.—Mespilus Saubli.—M.—2, Specimen too dried up; 3, Saxifraga cespitosa; 4, Saxifraga Wallacet.—Ann.—1, Gardenia-flowered Daffodil (Narcissus ponticum fl. pl.); 2, Eupatorium riparium; 3, Curculigo recurvata.—E. S. Hughes.—The Balaoric Sandwort (Armaria balcarica)—R. T. CLAY & SON'S LONDON'S FERTILIZER. Produces Flowers, Fruits, and Vegetables for Exhibition, Pleasure, and Profit, in the HIGHEST DEGREE OF PERFECTION. It is Safe, Lasting, Economical, & Unsurpassed for all Horticultural Purposes. AMATEURS WIN PRIZES WHEN USING IT. HAVE YOU TRIED IT? Sold everywhere in 6d. and 1/- Tins; and in SEALED BAGS—7 lbs., 2/6; 14 lbs., 4/6; 28 lbs., 7/6; 56 lbs., 12/6; 112 lbs., 20/-; or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order, except 6d. Tins. Full Price List of Manures, Chemicals, and Sundries upon application. CLAY & SON, MANURE MANUFACTURERS, STRATFORD, LONDON, E.

WILLEDEN GREEN ROT-PROOF SCRIM SHADING

Shading Conservatories, Greenhouses, protection of Fruit Trees, and other Horticultural purposes.

In use at leading gardens and estates.

Supplied in any quantity, 26 in. or 60 in. wide.

Blinds of all kinds made to order.

Willeden Canvas, Tents, Ground Sheets, Blinds, Awnings, Garden Aprons, and all purposes where a rot-proof and pliable material is required.

Willeden Roofing for Tool Houses, Sheds, Lean-to's, &c.

Samples free.

Telegraphic Address: IMPERMEABLE, LONDON. **WILLEDEN PAPER & CANVAS WORKS, LTD.,** Willeden Junction, LONDON, N.W.

GARDEN & PLANT PHOTOGRAPHS, 1902.

THE EDITOR OF GARDENING ILLUSTRATED announces Photographic Competition for the season of 1902.

Class 1.—SMALL GARDENS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best ten photographs or sketches of picturesque small gardens, including town and villa gardens, rectory, farmhouse, or cottage gardens.

Class 2.—FLOWERS AND SHRUBS OF THE OPEN AIR.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS to the sender of the best series of not less than twelve photographs of the above. These may include wild plants or bushes, or any plant, flower, or shrub grown in the open air, including also half-hardy plants put out for the summer, and either single specimens or groups, or the effects resulting therefrom, in beds or borders. Shoots also of rare or beautiful plants photographed in the house may be included in this class.

Class 3.—INDOOR FLOWERS AND PLANTS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best series of indoor plants—greenhouse, stove plants, Orchids, or any other plant not of the open air—either single shoots, plants, or specimens, or the effects resulting from good grouping or other arrangements of such plants separately or in association with others. Ferns or groups of Ferns in houses may be included in this class.

Class 4.—BEST GARDEN FRUITS AND VEGETABLES.—A prize of FIVE GUINEAS and a SECOND PRIZE of TWO GUINEAS for not less than twelve photographs of the best kinds of garden fruits and vegetables, Grapes, Peaches, Apples, Pears, Plums, Cherries, or any other fruit grown in Britain, to be shown singly or on the branches. Overcrowding, as in dishes or shows, should be avoided. The aim should be to show well the form of each kind, and as far as may be life-size. The object of this is to get good representations of the best garden fruits and vegetables under the old names, though we do not want to exclude real novelties when they are such.

Class 5.—GENERAL SUBJECTS.—A prize of FIVE GUINEAS will be awarded for the best twelve photographs of any garden subject not included in the previous classes, such as water gardens, waterside effects, rock gardens, picturesque effects in gardens, vases, cut flowers, table decorations, and pretty garden structures.

All competitors not winning a prize will for each photograph chosen receive the sum of half a guinea. In order to give ample time to prepare good photographs the competition will be kept open until November 29th, 1902.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron rods, wire, or iron supports of any kind, labels, and all like objects should be omitted from the photographs. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with thick backs, and the photographs should not be less in size than 5 inches by 4 inches. The subject should not be overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the sender whose they are obtained in the usual way, and whose the copyright of which is open to question must be sent. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly. Plain types and bromides should not be sent, but those so authorized and printing out papers are preferred for engraving. All photographs should be properly toned.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. Care should be taken to avoid the ink being seen on the face of the photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor, 11, Furnival Street, Holborn, London, E.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." Unsuccessful competitors who wish their photographs returned must enclose sufficient postage stamps for that purpose.

ACME Weed Killer.

"Weeds, weeds, everywhere. I wonder if that new gardener can suggest anything."

"Yes sir, I'm just using the 'Acme' Weed Killer. The best thing in the world for killing weeds."

FRUIT.

PRUNING FRUIT-TREES.

Pruning of espaliers, or, indeed, any other restricted fruit-trees, summer pruning is very important, from which control it gives the cultivator the trees. Should the bottom of the trees show any signs of weakness, then unpinned for a season or two, such more closely and assiduously the overgrowing parts, to direct the flow of the weaker parts. By pinching the top shoots of trees the flow of sap may be led in any direction. Pinching a shoot the flow, whilst leaving it unpinned, keeps the flow in that direction. The art of summer pinching is deserving of close study, not only in its application to trees generally, but the best mode of treating particular trees should be separately noted. There is too much variation in the growth of fruit-trees to permit all to be treated alike without in some cases causing serious injury to the health of the trees; for whilst a vigorous grower must be repressed, it may be necessary to leave the weakly one untouched, or by further means to encourage growth. Pinching, quite as much as root-pruning, enables the grower to power to be repressed, and in a natural and less hurtful way, because the tree can be given gradually and at the right time. In most cases summer pruning is delayed, often till the young shoots are 1 foot or more long and are getting firm at the base, and perhaps they are cut back to three or four buds. But during the time of this rapid growth the roots have felt the stimulus of so much foliage; and as in the case of cultivation is carried on almost up to the trunk of the trees, the roots have no time to strike downwards; and as this is year after year, the system of the tree out of order and refuses to bear fruit or fruit, and of course when that condition is reached the only remedy is to lift, root, and replant. But if the growth has been attended to earlier, a regular steady root system would have been carried on in proportion to the growth, for there is always a reciprocity of action between roots and trunk, and when the latter are encouraged or repressed to extend themselves, the roots, to the heavy demand made upon them, must extend into the moist subsoil; and when that is done nothing but watery unripe wood can be produced till the tree is lifted out of the soil, and its roots brought back to the surface. In the meantime a root or two is lost, and there is a possibility of the roots being trimmed in too much, and the tree will require a year or two to recover. In dealing with a well-balanced tree, the most reasonable way of proceeding would be to commence pinching when the longest shoot had grown 7 inches or 8 inches, and then cut them back to five or six buds, going on at intervals of three or four days till all were pinched or shortened back. In this way no undue pressure would

be played on the roots, and the tree would be maintained in a healthy and vigorous state through both roots and branches; the sap that ran to waste in watery spray would be directed into forming fruit-buds, and an early fruit-bearing habit formed that would tend still further to check any undue development of useless wood.

GOOSEBERRIES—PRUNING.

TO THE EDITOR OF "GARDENING ILLUSTRATED."
SIR,—For the last two or three years I have been pruning my bushes according to instructions in Mr. E. Holyday's book, "Fruit Culture for Profit," thinning out during June a lot of the young wood, both with the object of helping the ripening fruit and improving the shape of my trees—towards the latter purpose removing entirely much of the wood that has not an upward tendency. I think insufficient attention was paid to my bushes in their early training to give a sufficiently long stem on which the tree should stand, the result being that as the bushes get older many of the boughs hang about too near the ground. This I am endeavouring to improve by now removing a certain quantity of the lower portions and encouraging the young wood only that gives promise of a straight, upward growth. At the same time I thin out, where possible, the inner shoots, so as to aim at giving each bush in time the cup-shape form. So far my attention seems to have been successful as regards the size of fruit, but I have no doubt that another year I may lose in quantity by taking away wholesale a rather large quantity of the older wood, which seems absolutely necessary to ensure upright and more slightly growth. The kinds I grow are Industry, Keepsake, Whitesmith, and Crown Bob. I cannot help thinking that this treatment promises well for the future, while, at the same time, doing this in June I believe one deals a very severe blow to the insect tribes, as on the pieces cut off are often to be found caterpillars' eggs. I should like to hear your readers' opinion on this course, and also whether anyone can say if by any special rule in cutting back young growth—*i.e.*, leaving two or more leaves—fruit-buds are formed as in other fruits for another year? Or should the young shoots be cut off close to the branch they spring from? In the removal of some of the young shoots this might be useful knowledge. CLOS.

NOTES AND REPLIES.

Protecting orchard fruit.—I should feel greatly obliged if you or any of your readers could inform me the means adopted in the fruit-growing districts of keeping the birds off? I have 4 acres of Cherry orchard, with a large number of trees just in their prime, mostly planted twenty-five to thirty-five years since, and year after year the trees before the fruit is quite ripe. When I was a boy I have known the crop sold standing for £16 and £20. The fruiterer who bought them gathered and retailed them at 4s. to 6s. per lb. Since the introduction of so much foreign fruit it is a difficult matter to get anyone to buy the

crop standing, as the risk is: Who shall have the fruit—the purchaser or the birds? The fruit, if allowed to mature, is of a large size and exceptional quality. The orchard in question is situated in the Midlands. I have known the birds commence on a tree as soon as a light of a morning and strip it by 10 o'clock the same morning. CONSTANT READER.

Cordon Gosseberries.—I have some Gosseberry-trees three and four years old, grown as single upright cordons. They are 3 feet to 4 feet high, and bear fine fruit, but I do not know how to prune them. They are making strong lateral shoots every few inches. When should I cut them off, and how many eyes should I leave? I should be glad to know your opinion of growing Gosseberries in this way. JOHN PIR.

The great object of the grower of cordon Gosseberries must be to stock the stems full of fruiting buds. This is done by allowing the leader only to grow freely, whilst all side-shoots are pinched back to about three leaf-buds after they have made half a dozen leaves. As the outer of the three buds will push new growth later, such new growth should also be kept hard-pinned through the summer. This pinching not only keeps the fruiting-buds close home but the base buds swell up and bloom strongly the first spring. Winter pruning is limited to shortening back any growths that may tend to make the cordons bushy or branching. One advantage of growing Gosseberries as cordons is that by covering up the plants with fishing-nets the fruits can be protected from birds, and thus hang for a long time.

Peach leaves blistered.—I will feel obliged if you will tell me what is wrong with my Peach-trees, some twigs of which I enclose. They are growing in an open border, south aspect, in Cork. Leaves have been more or less curled in some way every year since planted six years ago.—K. P. B.

Many are the inquiries what best to do to prevent blister in Peach leaves. These are questions which it is difficult to answer, as sometimes under the most careful treatment, together with the use of night coverings, the trees are not always exempt from injury, though, of course, they suffer much less than others that have not received protection. So long as the foliage is dry, east winds and cold, frosty nights have less injurious effects. The one great thing is to watch that insects do not get the upper hand and cripple free development of growth. To guard against this the trees should be looked over almost daily, and any leaf which shows the least sign of curling may be taken as having some green fly behind it or on its under-side. The grower, with the aid of a Tobacco-dust distributor, should gently press the affected leaf between the thumb and finger, and after crushing the fly apply a little Tobacco-powder, the moisture from the insect causing it to adhere to the foliage, thus spring wetting it for the purpose. A good protection early in the season is a double thickness of Strawberry nets arranged loosely about 18 inches from the wall. This screens the trees from winds during the day and frost at night at the same time. Growth is not weakened by the exclusion of light and air, which is sometimes the case when thick blinds are not used carefully. See, also, reply to "Florence Betty" in our issue of May 10, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN

PLANTS AND FLOWERS.

OUTDOOR PLANTS

THE CHOICER GENTIANS (GENTIANA).

ALPINE and mountain pasture plants of classic beauty and variety, some herbaceous, some

Gentianella (*Gentiana acaulis*).

evergreen herbs, some annual plants. Beautiful as the Gentians are on the mountains of Europe—and it is not easy to describe their beauty at its best, as, say, of a plateau of acres of the Vernal Gentian on the Austrian Alps, or of the Bavarian Gentian along the side of an alpine streamlet—I think I was even more struck with the beauty of the American, fringed, and other Gentians which do not seem easy of cultivation in Britain. There is no serious difficulty as to the culture of the best European kinds, save, perhaps, bavarica, but the American kinds are more liable to perish in some of our soils. Gentians are not all worthy of cultivation on the rock garden. I never could see any beauty, from that point of view,

Smaller Cross-wort Gentian (*G. decumbens alba*).

in the tall and stately Gentians of the Alps, such as *G. lutea*, and some of the annual kinds are of no value for the garden.

If any plants justify the formation of a good rock garden, it is these; and, therefore, we should seek to get their best effect from an artistic point of view by, if possible, grouping them in a natural way. There will be no difficulty in this as regards some kinds, particularly Gentianella, which is very effective on some soils, and in its various forms might be treated well when sufficiently increased. The Willow Gentian leads also to good effect among the bushes in the rock garden, and

is readily increased. One or two good kinds, well grown and grouped, will be better than a dozen dotty examples of ill-grown kinds, however rare or curious.

GENTIANA ACAULIS (Gentianella).—This plant is too well known to need description, and happily, while among the most beautiful of the Gentians, it is easily cultivated, except on dry

very well in "battered" walls, and it flowered freely thereon. My friend, M. Francisque Morel, of Lyons, tells me that the form of this fine plant, which is cultivated in British gardens, is unknown on the Savoy Mountains and those near. I think it is an Italian form, but there are other handsome plants among its allies on those mountains and others near which are well worth the attention of rock

Cross-wort Gentian (*G. cruciata*).

gardeners. As the old plant we have is so easily grown in Britain, there is no reason why these should not be equally so. I think they would all do grown on walls in the way described in the first part of this book—that is to say, on "battered" walls against earth banks, with the stones so set that they will catch all the rainfall.

According to M. Correvois, there are four or even five well-marked forms of *G. acaulis*:—

GENTIANA A. ANHUSTIFOLIA.—A stoloniferous plant, emitting underground runners. Flowers

soils. In some places edgings are made of it, and where the plant does well, it should be used in every garden to some extent in this way. It is at home on the rock garden, where there is moist loam into which it can root. It may be successfully grown in pots, and that would be worth the trouble where the plant would not succeed in the open air from a very dry soil or any other cause. It is sometimes sold in Covent Garden in pots when in flower

Swallow-wort Gentian (*G. asclepiadica*).

in spring, and is readily propagated by division, and also by seeds; but these are so small and so slow in germinating that its propagation in this way is never worth the trouble. It is abundant in many parts of the Alps and Pyrenees. I have grown this plant

large, handsome, of a fine deep sky-blue colour, and spotted on the throat with brightly green. This is the handsomest species. It flowers in May and June, and is found on the calcareous parts of the Alps at an altitude of 3,000 feet to 4,000 feet.

G. A. CLERUS.—The flowers of this are of a fine dark lilac colour and have no green spots on the throat. The plant blooms in May and June, and is found on calcareous rocks of the Alps and the Jura range at an altitude of 1,000 feet to 5,000 feet.

G. A. KOCHIANA.—Flowers of a violet-blue

G. BAVARICA (Bavarian Gentian).—In size this resembles the vernal Gentian, but has smaller Box-like leaves of a yellowish-green, all its tiny stems being thickly clothed with foliage, forming close, dense little tufts, from which spring flowers of the most lovely blue, which seems occasionally flushed with a slight tinge of purplish-crimson.

be grown in well drained pots, using the same compost. In all cases it should be kept rather dry in winter. Young plants flower freely when only 2 inches or 3 inches high.

M. Correvon says it is a difficult one to grow, so that its culture is almost impossible. The seedlings of it which he raised in his alpine garden only yielded flowers in the proportion of hardly 3 per cent. A heavy, compact soil, which is almost clayey, and full

The Vernal Gentian (*G. verna*).

The plant is a native of the high Alps of Europe, and in 1868 I saw it in great abundance near the monastery of the Simplon. *G. verna* occurs abundantly in the same place; but, while it is found on ground not overflowed by water, *G. bavaria* is in bloom in very boggy spots, where some diminutive rill has left its course and spread out over the Grass, not covering it, but saturating it so that, when walked upon, the water bubbles up around. The best thing to do with it is to plant it near the margin of a rill, taking care to let no Carices, Couch Grass, Cotton Grass, or other straggling growing subjects get near the spot, or they would soon cover and destroy the plant.

Marsh Gentian (*G. pneumonanthe*).

It may also be grown in pots, plunged in sand during the summer; sandy loam to be the soil used, the plants to have repeated and abundant waterings from early spring till the heavy autumnal rains set in, or be half plunged in water, with free exposure to light.

exposure to the sun are the conditions which appear to suit it.

G. CRISTATA (Fringed Gentian).—A singularly beautiful plant, frequenting wet ground and river sides, something about 1 foot in height, with the loveliest fringed deep indigo-blue flowers we ever saw. It is an annual or biennial plant, very beautiful for the bog garden, if we could get it established in our country from seed. It grows in moist woods and pastures,

colour, marked on the throat with spots of blackish-green colour; in May and June. Common in pastures on the granitic Alps.

G. A. ALPINA.—Leaves small, of a brightly green colour, glistening, curving inwards and pubescent, forming rosettes which incurve at about the middle part of their length. It blooms in May and June. Found on the granitic Alps at an altitude of 10,000 feet to 9,000 feet; also on the Pyrenees and the Sierra Nevada. The two last-named species require a compost of one-third crushed granite, one-third peat soil, and one-third vegetable loam, and should be planted on a framework half exposed to the sun.

G. A. DINARICA (Beck.).—This is a form of *G. acaulis* with broad, thick leaves and erect, slender, almost cylindrical flowers of a dark blue colour. Found on the Alps of Southern and Eastern Austria.

G. ANDREWSII (Blind Gentian).—The kinds of Gentian which attract so much attention for their beauty on European mountains open their flowers wide when the sun shines. This does not do so, having closed tubes each about an inch long, in clusters, and of a deep dark blue. Then, instead of spreading low and mantling the ground with rosettes of leaves like *G. verna*, the shoots grow erect and 1 foot or more high. It is handsome, and grows quite freely in a sandy peat, but has been hitherto so little grown that experiences of its likes and dislikes are not yet obtainable. The flowers are closely set in clusters near the tops of the shoots. A native of moist rich soil in North America, flowering in autumn, and increased by division and by seed.

G. ASCLEPIADEA (Swallow-wort Gentian).—A true herbaceous plant—i.e., dying down every year, thus keeping out of danger in winter time, and easily cultivated in almost any soil. It grows erect, with shoots almost willow-like, and from 15 inches to 2 feet high, according to the nature of the soil; bearing numerous large purplish-blue flowers, arranged in handsome spikes. Little need be said of its culture, as it is not fastidious, but in a deep sandy loam or peat it will grow twice as large as in a stiff clay. In a wild state it inhabits Pine woods. In consequence of its tall habit, this species is best adapted for the bushy parts of the rock garden, or in the borders near at hand. It is a native of European mountain woods, and is readily propagated by division of the root.

the summer; sandy loam to be the soil used, the plants to have repeated and abundant waterings from early spring till the heavy autumnal rains set in, or be half plunged in water, with free exposure to light.

G. CRISTATA.—A rare and beautiful species, with flexuose, almost simple, stems about

Crested Gentian (*G. septentrionalis*).

1 foot high, bearing large, solitary, azure-blue, deeply fringed flowers, each from 1 inch to 1½ inches long; leaves roughish at the edges. It is a native of the Alpine regions of Central and Southern Europe, and the Caucasus, in dry pastures, and requires to be planted in a mixture of rich fibrous loam and broken limestone, in the fissures of rockwork; or it may

and also near rivers and streams, and has a wide range in N. America and Canada.

G. CRUCIATA (Cross-wort Gentian).—This species has erect, spreading leaves, arranged at right angles or cross-like on simple ascending stems, which are from 6 inches to 1 foot in height. The flowers are blue, and produced in whorls. It is a native of dry pastures in

Central and Southern Europe and Siberia, and has a four-angled creeping root, or rhizome, split into connate lamellae of four, and fibrous or hairy at the top. In growing this plant, fibrous loam should be plentifully mixed with small pieces of broken limestone.

G. DECEMBENS. (Smaller Cross-wort Gentian).—Stem erect, 12 inches to 16 inches high. Flowers numerous, of a fine blue colour, and borne in terminal spikes. Blooms from June to August. Native of Siberia, at an altitude of 2,000 feet to 3,000 feet. There is a good white form of this. Syn. *G. alscendens*.

G. GRANI.—A vigorous-growing species, forming dense tufts or carpets a foot high, with bent, ascending stems, and ornate, lance-shaped, blunt leaves, closely set. Flowers each nearly 2 inches long, in very large heads of a brilliant blue colour. Native of alpine districts in the Caucasus and Armenia. Grows well in rich, moist loam, and is easily increased by division or from seed.

G. KERMANS. One of the most beautiful of the Himalayan Gentians, and one of the easiest to cultivate. In the south of Scotland it does well, but then alpine Indian plants find there a congenial home. Near London, on a north aspect, it has flowered well. The compost on which it grows is a rich peaty mixture, and it receives copious waterings during the summer months. It forms a tuft, or rosette, of smooth leaves about 3 inches long, from the base of which rises the flower-stalk, and from the upper joints short stalks bearing single flowers, each an inch broad and of the brightest azure blue, in July and August. Himalayas.

G. PERMOVENSIS (Marsh Gentian). A British perennial, scarcely less beautiful than any alpine Gentian, with tubular flowers, an inch and a half or more long, of a beautiful blue within, with five greenish belts without, the lobes of the mouth short and spreading; on stems 6 inches to a foot high. A native of boggy heaths and moist pastures, and in cultivation requiring moist pent. It is not recorded from Scotland or Ireland, though not rare in some parts of England. Few plants are more worthy of a place on the rock garden, and where the plant occurs wild it might well be guarded against extermination.

G. RENSAEII (Pyrenean Gentian). Somewhat like the Vernal Gentian in size, but with narrow, sharp-pointed leaves and dark violet almost stalkless flowers, the flat portion at the flower being formed of five oral lobes, with a triangular appendage between each nearly as long as the lobes. It requires much the same treatment as *G. verna*, flowering in early summer, and is well worthy of a place in the choice rock garden, though not of such a vivid hue as *G. verna*.

G. SEPTENTRINA (Crested Gentian).—A lovely plant, bearing on stems 6 inches to 12 inches high flowers in clusters, widening towards the mouth, of a beautiful blue and white inside, greenish-brown outside, having between each of the larger segments of the flowers one smaller and finely cut. A native of the Caucasus, and one of the best for cultivation on the rock garden, thriving well in moist sandy peat. Division.

G. VERNA (Vernal Gentian).—The type of all that is beautiful in alpine vegetation. It covers the ground with rosettes of small leathery leaves, often spreading into tufts from 3 inches to 5 inches in diameter, and producing in spring, flowers that even the botanist calls "beautiful bright blue," though botanical books are usually above taking any notice of colour at all. Sometimes the blooms barely rise above the leaves, and at other times are borne on stems 2 inches or 3 inches high. A few things are essential to success in its cultivation, and far from difficult to secure. They are good, deep, gritty loam on a level spot, perfect drainage, abundance of water during the dry months, and full exposure to the sun. Grit or broken limestone may be advantageously mingled with the soil, but if there be plenty of sand, they are not essential; a few pieces half buried on the surface of the ground will help to prevent evaporation and guard the plant till it has taken root and begun to spread about. It is so dwarf that, if weeds be allowed to grow around, they soon injure it. In moist districts, where there is a good deep, sandy

loam, it may be grown on the front edge of a border carefully surrounded by half-plunged stones. It may also be grown in pots or boxes of loam, with plenty of rough sand, well drained and plunged in beds of sand, exposed to the sun, and well watered from the first dry days of March onwards till the moist autumn days return. In all cases good, well-rooted specimens should be secured to begin with, as failure often occurs from half-dead plants that would have little chance of surviving, even if favoured with the air of their native wilds. In a wild state this plant is abundant over mountain pastures on the Alps of Southern and Central Europe, and those of like latitudes in Asia.

SOIL FOR RAISING PANSY SEED.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—Passing some waste ground on which rubbish is being deposited, I (six or seven weeks back) observed a small mound on which there was a luxuriant crop of Grass, and on pulling up a handful of the latter I found the material below to be largely composed of mortar rubbish and some dark material which may have come from ash-pit or sewer in the locality. Thinking, on account of the fine crop of Grass, the stuff would be good to sow some Pansy seed on, I thereon procured a barrowful of it and made up a small bed a few inches deep, making at the same time a similar sized bed of fine sand, with a very little quantity of garden soil in it. On these two small beds I sowed some Pansy seed from the same package, covered each sowing with some fine sittings of the same soil in which the seed was sown, watered and otherwise treated each bed up to the present in the same manner. On the bed largely composed of the mortar refuse I have fifty fifty plants to ten on the other, the plants on the mortar bed appearing quite ten days before those on the other. About thirty-five years ago, when passing a large heap of mortar, mortar refuse, etc., I observed a small wild Pansy growing on the heap. I took it home, put it into a jam jar, even without a hole in the bottom, and placed it on an upstairs window-sill looking almost due south, not then knowing which aspect was best. The bloom that came on it pleased me so much that I took to rearing flowers. The jam jar was my first garden and the wild Pansy my first flower.

Belfast. ANDREW MAIZE.

NOTES AND REPLIES.

What is a herbaceous plant?—Will you kindly tell me what you call herbaceous plants, as I have heard several talk about it? One says all plants that die down completely in the winter are true herbaceous plants. Is that so? According to that, such as the Hollyhock would not be, as in my garden it has green leaves all the year. Again, do bulbs come in under that or not? The person I referred to above said that plants that did not die down were not herbaceous. T. TROSK.

[In garden language the meaning is perennials that die down every year, but you will remember that all such definitions are artificial, as in nature there are no hard-and-fast lines.]

Slugs in garden.—In reply to your correspondent, "H. C. F. D.," as a slug-infested garden, I have been recommended and have tried with great success a very simple and cheap remedy. Pure an orange, so as to keep the two halves as complete as possible, lay the peel mouth downwards on the beds infested by slugs, which creep inside and are easily gathered and destroyed in the morning. Woodlice and ants are also attracted by the odour and shelter. —AN OLD READER.

Hollyhocks.—It is now generally agreed that to avoid the dread disease which attacks Hollyhocks one should plant them out in well-prepared ground instead of, as is often the case, putting them into soil that is practically worn out. I have observed that where failures mostly have occurred it has been on impoverished land. But another preventive measure is to always have at hand a few young plants, so that if disease should assert itself one may soon uproot the offenders and replace both soil and plants at the proper time. To have Hollyhocks for another year one should sow seed from now until the end of July in boxes of fairly light soil, or on a warm border where the plants may receive a slight protection in the winter, planting them out in the desired places next March, previously prepared for the

ground by digging in during the winter some good cow manure. A succession of plants, young and healthy, is, I maintain, better than seeking to retain old stock, which is more liable to disease, and is of less value, from a flowering-point of view, than young plants.—WOODBASTWICK.

Two good early June hardy white flowers.—I often think were some of our hardy flowers occupants of the greenhouse, they would be more frequently seen in gardens. But because they may be had at a very small cost they are not valued so much. The two kinds I am about to mention are amongst the very best white flowers for the open border and to cut from. The first is *Aquilegia vulgaris*, single white. Nothing can be more lovely than a large mass of this. I have a group of it, the plants about 2 feet high, and a mass of bloom. This kind is grown for massing on the Grass. So free is it that it seeds most abundantly and thrives in any soil or situation. It grows and blooms abundantly in a gravel path. Beautiful as this is I consider *Narcissus poeticus plenus*, or Garden-flowered, equally good. I know this is largely grown as a cut-flower for market. But in few gardens can one find it. Surely it is so from its expensiveness, seeing how cheap bulbs may be bought. Neither is it difficult to cultivate, given a good soil and an open position. With me it blooms equally well in borders and in the Grass, and I often have a in bloom at Midsommer Day in a shady border and in the Grass. —J. CROOK.

Foxgloves.—These look well as a back-ground to mixed borders, associated with Larkspurs, Dahlias, Hollyhocks, and other tall-growing plants. Instead of only the ordinary purple and white kinds there can now be found flowers with rose, lilac, pink, and bluish exteriors, the blossoms large and of fine form, and the throat or lip very handsomely spotted. It is in this rich, bold spotting that the beauty of the Foxglove so much consists. The small brown spots characteristic of our wild Foxgloves have been converted into large, rich, dark blotches and spottings, and when these markings are in combination with pure white tubes the effect is strikingly beautiful. Foxgloves are now getting into full bloom, and in the case of extra strong plants there is first the massive centre or main spike, and then a number of side growths come forth later. Those who do not require to save seed should cut out the centre spike as soon as it gets shabby, and the side shoots will be considerably benefited thereby, especially if good supply of water be given at the roots in dry weather. In the case of the best varieties a side shoot will supply an abundance of seed. If the seed be sown early in spring the plants will become strong for planting out in autumn, and will flower the following June.

Double Wallflowers.—It is fair to judge of the merits of the German strain of double Wallflowers by the group of these plants shown recently at the Drill Hall, and of their kind, they were very fine. Certainly there is little prospect that they ever will supersede in public esteem the beautiful small forms of which now we have so many, and which, when in bloom, are so sweetly perfumed. The German Wallflowers seldom branch, and chiefly produce one somewhat massive spike of double flowers on a stout woody stem that is fairly well clothed with leafage. But even in bloom the plants are very stiff and formal, and as a group at the Drill Hall I have never seen anything so plants more so. How much in seeing these German varieties one deplores the absence from gardens of the fine old yellow, red, and black perennial double Wallflowers. The great wealth of variety in the singles, however, gives some compensation. —A. D.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1. Mrs. Kennet Were, Cotlands, Sidmouth, for *Magnolia Soulangeana*; 2. Mr. J. Armstrong, Cemetery Road, Linthorpe, Middlesborough, for border of seedling Polyanthuses.

FERNS.

ADIANTUM TENERUM VAR. FARLEYENSE.

Will you kindly tell me how best to grow this Fern? I have a plant of it, but I cannot succeed with it. I grow it in peat and silver-sand. I have been told to grow it in loam and some manure mixed with it.—J. A. SIMPSON.

[At one time, when Ferns were invariably grown under green glass and heavy shading, this Fern was of no service outside the stove, and much of its beauty was lost, as it is only when exposed to the light that the young fronds take on the lovely rosy-pink hue. Another advantage in growing it fully exposed to the light is that the fronds will last well when cut. Plants grown from single crowns are by far the best, and as fertile fronds are never produced it must be increased by division. It is always best to divide young plants. If done before the pots get too full of roots the divisions will soon start into growth. Where old plants are to be had they may be broken up so as to secure some good roots with each division, and then be divided again after they have begun to grow; or some of the crowns may be taken off and all the fronds cut away. If put into Sphagnum Moss, peat, and sand, and kept close, they will soon start

FERNS AND SUNSHINE.

Ferns dislike bright sunshine, thriving best where the atmosphere is constantly moist and the light of a subdued description. At the same time, it must be admitted that Ferns are often subjected to treatment which is far from being in accordance with their nature and requirements. Many growers either heavily shade their Ferns during a great portion of the day, or create dense perpetual shade by damping the glass with a mixture of some kind, not appearing to realise the fact that Ferns, like other plants, require a certain amount of light to build up their tissues; and that when unduly deprived of its influence the foliage cannot well attain its due amount of healthy vigour. There are some species which will thrive in very shaded positions; others, again, such as the generality of the Adiantums, require a considerable amount of light, and are even benefited when they catch at some part of the day a portion of the sun's rays. Many of our most beautiful stove species, such as the Gold and Silver Gymnogrammas, seldom retain their vigour and beauty long unless placed in a very light position. Those who would wish to form a correct idea of the requirements of the Fern tribe in this respect should visit their native haunts. There they will see at a glance

An ugly wall made beautiful.—A small conservatory opening into drawing-room had an angle which seemed past decoration, as no plant stands seemed to fit. Finally, the wall was covered with zinc to prevent the house wall being injured by damp. Wire netting of medium mesh was fastened in front of this so loosely as to admit of Moss to about $\frac{3}{4}$ inch in depth to be tucked through the interstices in the mesh. Into this Moss, Ferns of the smaller kinds, Sedums, Begonias, etc., were tucked, no earth being allowed with them, and being syringed in summer twice daily have grown and seeded, and have even received additions from the outside world, such as Wild Strawberry, Speedwell, etc., which have apparently made their entrance through the open door of the conservatory, and found a congenial home. The space is now a many-shaded mass of cool green, varied later on by the pale pink flowers of the Begonias and the quaint lavender bunches of the Sedum. This plant wall has grown in beauty for the last ten years, and shows no sign of failure. M. I. IRVING, *Tiverton, Devon.*

ROOM AND WINDOW.

FLORAL DECORATION.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR.—I feel so much in sympathy with "S. W. F." on the subject of floral decoration, that I am moved to reply to his charming article in last week's issue of GARDENING ILLUSTRATED. The opening remarks refer, I think, to an article of mine written about this time last year, fresh from the impressions of some barbarous judging. "S. W. F." is doubtless speaking from experience when taking exception to my expression of doubt as to the existence of any very fervent love of flowers in the breast of the Rose exhibitor. I, too, speak from experience, and apparently our experiences differ.

Exhibitors as a body are not "powerless to make any alteration" they please in the rules and regulations, and so long as they elect to exhibit Roses like pin-cushions, so long must they be regarded, I think, with suspicion as to their real love of natural beauty. I do not remember making any statement implying that "the admirer of the champion bloom at the National Rose Show necessarily ignores the charm of the blossom-laden sprays of our garden Roses," but I plead guilty to being an "individual of limited intelligence." When I have the good fortune to meet one of unlimited intelligence the case shall be put to him for a decision. S. S.

FLOWERS IN VASES.

PERHAPS there is no operation in gardening which is performed with less taste, as a rule, than the arrangement of flowers in vases. We generally see a host of different kinds of flowers packed as close as they can be got together, great care being taken that the whole shall present an even surface when placed in the vaso, and the object appearing to be to get as many different kinds of flowers into one receptacle as is possible. Now, to properly enjoy a vase of flowers, one kind, or at most two, should only be used. Take a handful of flosses or Gladioli or Dahlias, and place them in a vase, and they are effective; place them together and one destroys the effect of the other. The single Rose bloom, with a few leaves and buds, placed lightly in a small vase or glass, will afford ten times more pleasure than a handful of different kinds of flowers crammed into the same receptacle. The eye, as a rule, can only enjoy one object at a time, and this should be kept in view when arranging flowers in vases. We do not say, of course, that a few Fern fronds or light Grasses may not be used with advantage, provided they are tastefully disposed.

Rhodanthe Manglesi.—This Rhodanthe was not one time regarded as a difficult plant to grow, but our market growers now-a-days do not look upon it in that light, as the numbers that are to be seen exposed for sale in the streets of London will testify. Like Mignonne, the Rhodanthe is very impatient of being

Adiantum tenerum var. Farleyense.

away, and may be potted singly after they have made a few fronds.

Soil.—The best compost for putting in fibrous loam, some horse-manure, which has been well dried, and some sand. If the manure is heavy some peat may be added, but if otherwise it is unnecessary. Good drainage is important, and when potting the plants they should be put fairly well down but not buried too deeply. The fresh soil may just cover the crowns, and should be pressed moderately firm. Great care as to watering is necessary. Newly-potted plants, or those with few fronds, will not require much, while healthy pieces with large fronds and the pots full of roots will take an abundant supply. Letting the plants get dry is a sure cause of failure. Weak liquid-manure, too, is beneficial when the pots are well filled with roots. This Fern should never be grown under the shade of other plants or crowded in any way. Stand it up on an inverted pot or hang it from the roof, with plenty of air circulating round it, in a temperature of 60 degs. or 70 degs. It is not so much heat that is required as a regular temperature, and where it cannot be sustained it is better to keep the plants on the cool side. If large specimens are wanted pot on from time to time, taking care that this is done before the plants get too much pot-bound.]

that every plant receives a large share of filtered light; they will note that in every case, although the plant is well sheltered from the glare of a hot sun, it invariably turns towards the light; and in most cases it will be found that either the morning or evening sun reaches it. If the grower takes Nature for his guide in this matter he cannot err. Whether his plants be grown in a glass structure or in the open air the same rules will apply. A slight shade of tiffany, to be applied only when needed, is all that is required; and if the structure has a north aspect, but little artificial shade will be required. The plants will get a maximum of light without being subjected to the dryness which is apt to prevail in a structure so situated as to be exposed to the summer's sun. These remarks apply equally well to the construction of Ferneries in the open air. Choose, if possible, a situation where the plants are completely screened from the noontday sun, but where they are at no time densely shaded. The north side of a wall or building, or a situation in the immediate neighbourhood of tall trees, where the early morning sun, as well as its departing rays, penetrate—where the atmosphere is at all times cool and moist—is just the place in which Ferns thrive, and attain a luxuriant development.

disturbed at the roots, so that it is sown in the flowering pots, which is the regulation 4½-inch or 5-inch pot. The soil is pressed down firmly, and in doing so it must be borne in mind that the seed is to be sown on the top and then covered with soil, so that sufficient space must be left for watering. Good drainage must be ensured, for though the roots are very impatient of stagnant moisture, they at the same time quickly suffer if allowed to become too dry. A free circulation of air around the plants when growing is very necessary, for mildew is liable to attack the foliage, which is soon permanently injured. Besides *Rhodanthe Manglesi* and its white variety there are other forms, as *atro-sanguineum* and *maculatum*.

ROSES.

HINTS TO EXHIBITORS.

How disappointing that Roses are so late. At the time of writing I could not cut a bloom from outdoors, save Scotch Roses, Rugosa, Austrian Briers, and the like. And yet on the Devonshire coast I hear Roses were never finer in bloom, and the flowers wonderfully good. If the rain would cease and the sun shine out, Roses would be fine this year, the foliage being so healthy and the buds promising well. One cannot give liquid-manure in such weather as we are having, and yet the bulbs, perhaps, require a little help where exhibiting is carried out. A teaspoonful per plant of guano will effect a marked change. This may be repeated in a fortnight, but should not be given when buds show colour. Another good, safe artificial mixture is nitrate of potash and phosphate of potash. Mix both together, and give each plant a teaspoonful at once, and again in a fortnight, hoeing it into the soil. In localities where there has been little rain these two ingredients may be given in liquid form at the rate of 1 oz. each to 1 gallon of water, only before applying this stimulant give the plants a good watering with clear water. Amateurs are often over-anxious about feeding their Roses, and probably more harm than good is done by the reckless use of artificial manures. I have seen plants killed outright by the excessive use of such.

Disbudding must be done at once, but the work should be carried out by a trustworthy individual. I believe in disbudding at the earliest possible moment, for a great strain is put upon a plant when it is producing its flowers and seeds, so that if we reduce the number it follows that those left must receive the double share of nutriment. But the art of disbudding lies more in knowing which kinds to dishud and which to leave alone. Generally speaking, all Tea Roses of large size and double flowers pay for disbudding, not merely by reducing the buds to one per shoot, but also in pinching in the young growths which start from the axils of each leaf. As the season so far is a wet one, a plant will be able to perfect more buds than would be the case when the weather is hot and dry. Great care is necessary in disbudding Roses that produce very double flowers. Sometimes the centre bud is quite deformed, and it is better to remove it and reserve one of the side buds. Roses, such as *Captain Christy*, *Victor Verdier*, and, in fact, most of the latter race, should have the centre buds removed, for they most frequently come malformed. Before removing buds make sure that those about to be retained are perfect as far as can be judged from outward appearance, and also see that no maggots are lurking in them. Maiden buds budded last year yield, as a rule, the best blooms, but they are rather later than cut backs. By disbudding these very early, magnificent flowers are produced. If the ground is in good condition these young plants will be better without artificial aid in the shape of manures.

Protecting the blooms has now become quite a business, and it is a necessary aid to successful competition. There are several protectors in the market, but any ingenious man could make one. A cone-shaped frame of wire, covered with strong canvas steeped in oil and painted a light green or white outside, makes a capital protector. Stout deal stakes firmly set in the ground, with holes at varying

distances, enable the grower to raise or lower the shade at will. Heavy dews are bad for Rose blooms, and rains also, but they cannot have too much air and sunshine. It is necessary to shade from the latter certain blooms when they appear too forward, and some very dark Roses are benefited by shading, otherwise I prefer not to shade only when the flowers are liable to injury by rain and dews. A severe thunderstorm and gales of wind are very trying to the exhibitor, and the protectors must be secured thoroughly or more harm is done than if the flowers were unprotected. It is very necessary for the exhibitor to support the growths of slender varieties grown as dwarfs of such as *Marie Baumann* and most of the Teas, or the weight of their beautiful blooms will bend the growth to the ground. On the day prior to the show the most promising half-open flowers should have their centres tied with a piece of soft wool or Raffia. I much prefer the wool, as it is more easily removed. The outer row of petals should not be tied up, only the heart of the flower. In many instances this tying will improve the flower. Thin varieties, such as *Victor Hugo*, *Fisher Holmes*, need tying most. In tying make the first turn of an ordinary knot and then repeat it; this will prevent the wool from slipping off. The ties are kept on the bloom until the last moment at the show, but when in the show tent it is often found necessary to loosen the tie before the hour of judging. A really first-rate exhibitor knows to the minute how long a bloom will take to grow to its most perfect phase of beauty. Do not tie blooms when damp with rain or dew, but wait until sun and air have dried them.

STAGING THE BLOOMS.—A great point is to have a good tube. The labour of wiring or tying a stick on the stem of each flower is known no more by the use of these tubes. It is half the battle in winning prizes to be able to stage the blooms well. Nothing can teach the novice better than an hour's experience at a good Rose show. The standard of excellence should also be observed. What is known as a three-point flower is the one to aim at in producing. Form stands first, then colour. I would advise all exhibitors to have plenty of spare blooms with them. It is surprising how a bloom will grow in a single night. What appears a grand flower when cut in the evening is often past its best at time of judging, so that plenty of young flowers should be taken to the show. For this purpose a travelling box for spares is necessary. I have found the best to be as follows: 4 feet long, 2 feet wide, 15 inches deep, made of ½-inch wood. Zinc tubes are tacked on to the bottom. Those tubes are 6 inches deep and 1½ inches in diameter. They will hold comfortably three blooms each, and the box will take about thirty-six tubes, so that over one hundred flowers may be taken in one box. I would rather take all my Roses in such a box than attempt to carry them in a shallow show box on a hot day. The greater quantity of water and cooler interior would be all in one's favour. The flowers could then be selected on the show ground and transferred to the show-box. For competing at the National Rose Society's exhibition it is necessary to have boxes of specified dimensions, which the secretary will give on application. As to the

TIME OF CUTTING, if one is near the show ground I should cut before four o'clock the same morning, but the flowers must be marked overnight, which they would be if tied as advised. Any old bloom looks lovely when bathed in dew, and unless marked we are apt to be deceived. If living a long distance from the show, of course the flowers must be cut overnight. After six at night is a good time to cut. Teas may even be cut in the morning of the day prior to the show should the weather appear threatening, or if one has a large flower that the sun would compel to expand, such a bloom may be preserved in a cool cellar for two or three days. I have used some Tea blooms two or three times in one week by thus keeping them cool.

ROSA.

Rose Fortune's Yellow.—Can any of your readers kindly inform me whether the *Rose Fortune's Yellow* (or *Jaune de Fortune*) flowers twice?—FRANCES.

NOTES AND REPLIES.

Rose Mercedes (Rugosa).—This beautiful new *Rugosa* will be very welcome, for its buds and open flowers are almost as shapely as a *Tea Rose*, and the colour also resembles an old favourite in that group—*Souvenir d'un Ami*—excepting that there is more white and silvery shading. It is large for a *Rugosa*, and its blossoms are double and sweetly scented. The growth is vigorous, which makes this *Rose* and all the tribe so very valuable. It is very gratifying to find raisers are obtaining such distinct breaks in this valuable group. There is another kind—*Conrad F. Meyer*—that one would imagine to be a *Hybrid Perpetual* if the growth were not examined. It is of a beautiful silvery-rose colour, and exquisitely perfumed.—ROSA.

Rose Beaute Inconstante (Tea).—This is a many coloured *Rose* of splendid growth. It is really a remarkable variety, producing various coloured flowers from satiny-pink to bright red and even deep orange red; all these shades appear on the same bush. The last colour is the one most admired. Under glass this tint seems to predominate, and as the plant becomes older the colours and variegations outdoors are very curious. It is a very free bloomer, and a *Rose* everyone should possess, if only for its novelty. The growth is very strong, but yet not extra vigorous. The raiser, *Monsieur Pernet-Ducher*, informs me that it resulted from a cross between an unnamed seedling *Noisette* and *Mme. Falcet*. The seedling *Noisette* was raised from an old variety, *Earl of Eldon*, and its colour was something in the way of *Beaute Inconstante*. This latter is sweetly fragrant. The reddish wood and foliage are very beautiful in June, when the foliage is in the tender stage in which all *Roses* are interesting.—ROSA.

Roses and the frost.—Considerable damage was done to *Roses* by the exceptional frosts we experienced in mid-May. Growths which had reached a length of about 6 inches are quite blackened in many cases, and the leaves have the appearance of being burned. The flower-buds, too, are quite worthless. I have gone over my trees and cut away all such damaged shoots as it is useless to expect them to recover. Far better let the plants put forth other shoots even if the blooms come late. Dwarf plants are the worst hit: the standards seem to pass through without damage. The Teas and *Hybrid Teas*, as may be expected, are those which cannot stand frost with impunity. At least, the former class is known to be tender, and I fear the latter is almost equally so. Both classes are quicker in growth than are the so-called *Hybrid Perpetuals*, and will, therefore, soon make up for the loss of a few shoots when we get warmer weather.—H.

Pruning free-growing Roses after flowering.—Many of the quick-growing climbing *Roses* are amongst the most ornamental climbing plants. When used where they can ramble at will, such as amongst the branches of thinly-clad trees, over large arches, or for covering fences, then they may often be allowed to go untouched for years, and when grown thus they are really the most beautiful. It often happens that many growers have not accommodation of this kind where they may let them grow, and are obliged to restrict them. Then arises the question when to prune or cut them back. If the young shoots are pruned away in winter or spring, then the summer following there is comparatively no bloom, and if allowed to go they get out of bounds, and reducing of some sort has to be resorted to. I have them growing under both conditions, and in no place are they more lovely than in a *Dundee Rambler* growing up amongst the branches of a large dead Holly, 20 feet high. Others are growing on low arches that formerly went over the old meat. The space is small, and I have to keep some within bounds. Cutting them back to the same height every year makes them look hedge-like. About every three or four years I cut them moderately low down just as they go out of bloom, and then they soon break, throwing out strong shoots. In other years they are reduced immediately after flowering, and in this way I have a good bloom on the growing wood every year.—J. CROOK.

TREES AND SHRUBS.

RHODODENDRON KEWENSE.

This, a plant of which growing in the dell at Kew we figure to-day, was raised in the temperate house at Kew in 1875 by the late Mr. Sinder from a cross between *R. Griffithianum* and *R. Hookeri*. Of the numerous plants raised, none bloomed until the spring of 1888, since which time they have flowered every year, and as a rule, with great freedom. At first grown in the temperate house, they were afterwards planted outside in a peat bed, where they could be protected by a canvas covering during hard weather. For many years they have at Kew been growing in the *Rhododendron* dell, with no other protection than a naturally sheltered position such as this affords. Many of the flowers measure between 4 inches and 5 inches across. Although the whole of the plants came from a single pod of seed, they vary a

SOME GOOD HARDY DAPHNES.

Most lovers of plants are familiar with the somewhat tender indoor *Daphne indica* or *odora*. While this is so, it is strange how few people are acquainted with the lovely hardy kinds, and even in gardens where hardy trees and shrubs are grown largely one seldom meets with *Daphnes*. I believe that many would grow these hardy kinds were they brought to their notice. It is no uncommon thing to see in gardens many coarse-growing shrubs in small beds and on the outside of borders, in positions they are totally unfitted for from their rapid growth, needing much cutting in to keep them within bounds, where such low-growing subjects as these *Daphnes* would be quite at home, giving no trouble in this way. Few things would be more enjoyable planted near the windows of dwelling rooms than a bed of mixed kinds, or single plants may be mixed with other shrubs and hardy plants. The centre may be formed of *D. Mezereum*, with such kinds

most vigorously in the Bagshot Nurseries. In this garden, where the soil is heavy, I find it needs some light soil mixed with the staple. The most common kind is *Laureola* (or *Spurge Laurel*). This grows rapidly in any free soil, forming large masses. The variety *pontica* is somewhat like the above, but blooms a month after that kind. I have a plant of this kind growing in the rock garden, and in a shady position facing north. Here it thrives well. During the last half of April and through May it is a mass of bloom, and although the flowers are not very showy at a distance, when brought close to the light they are attractive, being an ash-like white, and when in bloom this fills the air with its delicious perfume.

Where *Daphnes* thrive few things are more appreciated for cutting. I have now on my table a spray of *D. Laureola pontica*, and it scents the room. As a low-growing kind nothing can be more lovely than *D. Cneorum*, its deep pink-coloured flowers at the tips

Rhododendron kewense in the dell in the Royal Gardens, Kew. From a photograph by G. A. Champlin.

good deal in the colour of the flowers. Some on first opening are white, with a pale rose tinge, becoming almost pure white after a few days; others are of a more decided rose; whilst the richest coloured of all has buds of a rich rosy crimson and the flowers of a deep soft rose, which never loses its rich warm tint. All the forms are beautiful, and the different hue of the one only serves to bring out more vividly the loveliness of its neighbour.

When its parentage is considered, the hardiness of *Rhododendron kewense* is remarkable. Little appears to be known of *R. Hookeri*, and we have not heard of its being grown outdoors in the London district. *R. Griffithianum*, too, can only be grown at Kew as a cool greenhouse plant, yet there are plants of *R. kewense* that have been grown without any artificial protection in the dell at Kew for many years, and have withstood, consequently, amongst others, the winter of 1894-5 without any injury.

as *Fioniana*, *Laureola* (*Spurge Laurel*), and its variety *pontica*. The lovely *Cneorum* would make a glorious piece of colour if used as an edging to the bed. In this way the blooming season would extend over a long period. The *Mezereum* often is seen in flower early in January in sheltered spots, continuing many months. I have often observed how well this thrives in farmhouse and cottage gardens, showing it does not like being disturbed. Neither is it fastidious as to soil. I have seen very large plants growing on the light soils around *Ablershot* blooming most profusely, and in some cottage gardens in our villages in West Dorset it does equally well, although the soil is of a vastly different character. There are several kinds differing slightly in colour, and a double white kind, which I could never get to grow in North Hants, and have never seen a good plant of. *D. Fioniana* is a slender upright grower with purplish flowers. This used to thrive well in North Hants, and grow

of the shoots forming quite a cushion when it does well during spring, and again in autumn it is valuable. This thrives best in a light soil. In a garden in North Hants it grew rapidly. I used it in the hardy plant border in conjunction with evergreen *Camlytufts*, *Lithospermums*, etc. With me it grows from 12 inches to 15 inches high, forming masses from 2 feet to 3 feet across, and when seen in bloom is not easily forgotten. In the Bagshot soil it used to be quite at home, although it may be grown in a dry, sandy loam. In the rock garden all of the *Daphnes*, especially the low-growing kinds, may be used with the best results.

Forde Abbey, Chard. J. Crook.

Mespilus Smithi (syn. *M. grandiflora*). — Some specimens of this sent to us for name remind us of this tree, which is well worth growing, although it is not very common in English gardens. The pure white flowers are

in fine contrast to the dark green abundant leafage. M. Smithi is one of the best of holly trees, the full rounded head presenting a fine mass of foliage, while the graceful branches touch the turf. It is quite as beautiful as the common Medlar, picturesque in aspect, free flowering, and in every way a tree for the outskirts of the lawn.

GARDEN PESTS AND FRIENDS.

THE WINTER MOTIL.

I would be obliged if you would inform me the name of the insect enclosed, and the best means of destroying it? I have over an acre of orchard, which is planted chiefly with Apple-trees. The trees have a beautiful bloom, with every prospect of a heavy crop of fruit. I am afraid this insect has spoiled expectations of any thing like a good crop.—A. JONES.

[The insect attacking your fruit-trees is the caterpillar of the Northern Winter moth (Chimantohis boreata). The females of this species, as well as those of the winter moth, which is very closely allied to it, have only very rudimentary wings, or sometimes none at all, so that they are quite unable to fly. The chrysalides of these insects are formed in the ground. When the female moths emerge, the only way they have of reaching the young buds to lay their eggs is by crawling up the stems, so that the object of the fruit grower is to prevent them from doing so, and it is for this reason that sticky bands are put round the stems so as to catch the moths if they try to cross them. These bands should be put into position early in October, as the moths in some seasons begin then to leave the chrysalides. The sticky material should not be put direct on to the trunk of the tree, as it so clogs the bark as to injure the tree. The bark should be scraped rather smooth, then a strip of paper, known as grease-proof paper by hattermen, should be fastened round the stem about 1 foot or so from the ground; the ends should be made to overlap well, and the strip should be tied top and bottom so that the moths cannot creep underneath, and should then be thickly smeared with cart grease. This material is found to last longer in a sticky condition than any other. The bands should be examined every now and then, so that if the grease has lost its virtue or has become so clogged by the number of moths caught on it that it is no longer of any use, a fresh coating of grease should be applied to it. The bands should be kept in working order until the middle of January. In the case of espaliers or trees that are supported in any way, the supports must be banded as well as the stems. In spite of all precautions some moths manage to gain access to the buds; they are probably carried there by the males when pairing. The caterpillars are hatched soon after the leaf buds open. As soon as any are noticed, the trees should be sprayed with one of the following mixtures: A solution of paraffin emulsion, or 4 lb. of Paris-green (dough in a paste) dissolved in 75 gallons of water, to which add the same amount of lime as Paris green, bulk for bulk. Keep this mixture very thoroughly stirred, as the Paris-green is very heavy, and soon sinks to the bottom. It should be applied to the leaves as a very fine spray; the leaves only just require to be wetted and not to drip. Spraying should not be carried out while the trees are in blossom, and it must always be remembered that Paris-green is a rank poison.—G. S. S.]

NOTES AND REPLIES

Wireworm destroying Carnations.—Will you kindly advise me in your next as to the following: Several of my choice Carnations and Pinks (such as Uriah Pike, Germania, Baby Castle, Miss A. Campbell, Mrs. Pettler, Mrs. Muir, etc.) are drooping now they are coming into flower, and this morning, upon examining some of the roots, I found them infested with small, active, whitish worms (young wireworms?) that have been eating up the insides of the plants. The soil is turfy loam that was a meadow before the house where I live was built, and before planting last February I had some well-decayed manure worked in. Is it responsible for the worms attacking the roots? The plants do not lack for moisture. There is a heap of old lime outside my garden, left by the builders when this house was built about two years ago, and I have spread some of it round the plants, hoping, with the help of watering, to drive the worms away from the roots. Would this do any good?—U. WILLIAMS.

[Your Carnations have been attacked by wireworm, which was in the soil of the meadow

you refer to. We fear there is little chance of your getting rid of the pest so long as the Carnations are growing. The best way would be to give the soil a good coating of gas-lime, fork it into the ground and let it be fallow for a year, frequently stirring it up with a fork. You might, in the meantime, put slices of Carrot on the end of pointed sticks. Place these slices a few inches under ground, and examine them daily. You will find the wireworms in the Carrot slices, when they may be easily destroyed.]

Insects on Apple-tree leaves.—I send you a box containing some leaves, the trees of which are infested with the insects you will see on the specimen leaves. Will you kindly let me know what I am to do to eradicate the pest? There is little fruit on the trees, which are young plants.—S. R. RAY.

[The insect attacking your Apple-trees is one of the many species of aphides. The larger insect was the grub of one of the "three-winged flies." These grubs feed on the aphides and kill enormous quantities of them. The best way of destroying the aphides is to spray the leaves with a solution of paraffin emulsion. Be sure that the insecticide reaches the under-sides of the leaves where the aphides are. It does not much matter whether the upper surface is wetted or not. A good look-out should be kept in the spring for the pests, and the trees should be sprayed as soon as any can be seen again later if required.—G. S. S.]

Beetles on Rose-leaves.—I have noticed several of the little green beetles I enclose on my Rose-bushes, and shall be glad if you will tell me whether they do harm or good?—PARK EAU.

[The little green beetles you find on your Rose bushes belong to that very destructive family of beetles, the weevils. They are sometimes known as the "green leaf weevils;" their scientific name is *Phyllotus maculicornis*. They feed on the leaves of the plants that they infest, and unless in large numbers do but little harm. At times, however, when very abundant, they have been known to almost entirely strip a tree of its foliage. I do not know of any way of destroying them but picking them off by hand or sinking them off on to a newly tarred or painted board or sheet. This operation should be performed on a dull morning, as the weevils are then less likely to fly away when disturbed than if the sun is shining.—G. S. S.]

Insects on Apple and Pear-trees.—I enclose some insects principally infesting the Pear-trees, but also Apples, and numbers on the Pear. They are, you will see, male and female, the one has a red body, and the other black. What are these, their habits, and best method of prevention and making clearance of the pest?—WILKINSON.

[The flies you find infesting your fruit-trees and Pears are very common at this time of year, and often occur in large numbers together. They are perfectly harmless, and will not injure your trees or plants in any way. Their grubs, however, feed on the roots of plants, and are sometimes the cause of injury to them. These flies are very near relatives of the thus commonly known as St. Mark's flies, on account of their generally making their appearance about St. Mark's Day. They, however, are a different species, but belong to the same genus. The flies you send are *Bibio hortulanus*. They will all probably disappear in a day or two. They seem to be particularly common this year. The black individuals are males.—G. S. S.]

Worms in the garden.—A friend living in a neighbouring town has a small garden entirely surrounded by a brick wall, and after sunset it is simply alive with enormous worms, the ground being absolutely covered with them. Am I right in thinking they are injurious to the garden, where things certainly do not flourish, and whether there is any good way of getting rid of them?—K. A. MARSHALL.

[I do not think that worms are in any way injurious in gardens, except when they draw young seedlings into their burrows, which is not often. Darwin proved that they were of the greatest service in many ways by burying dead leaves and other vegetable matter, by bringing up fresh soil to the surface, and ventilating the soil. Many persons wish to banish them from gardens on account of the worm casts that are so abundant on lawns, especially in the autumn; but the casts when dry will soon break up when the lawn is swept and the fresh fine soil is beneficial to the grass. If the garden in question is freely visited by thrushes, blackbirds, etc., I should certainly not interfere with the worms in any way; but if the garden is in a town, it is quite possible that

they have increased in undue proportion, as their numbers have not been kept in check by their natural enemies, in which case it would be well to reduce them without trying to exterminate them. Watering with lime-water in wet weather when the worms are near the surface will bring them out of their burrows, when they should be collected. To make the lime-water, pour 10 gallons of water on 5 lb. of freshly slaked lime, stir it well two or three times, then let it settle, and use the clear water.—G. S. S.]

INDOOR PLANTS.

FORCING DAFFODILS.

It may seem at first sight somewhat out of place to call attention to Daffodils at a time when the latest species have hardly begun to flower, and a few of the Narcissus poeticus, both single and double, are still lingering in shady places in our gardens; but all true Daffodil growers know that this is just the right season for lifting the bulbs. I prefer to take mine up about the third week in June, but this year the bulbs will scarcely have ripened before the early part of July. Some growers take them up when the leaves are only partly withered, but it is best to wait until they are almost, if not quite, brown and shrivelled. The great thing is to lift the bulbs before the fresh root growth begins; this appears to commence as soon as the leaves are thoroughly exhausted, and it is, of course, quite evident that if the new root growth has proceeded far before the bulbs are taken up and dried, these bulbs must be the weaker to the loss of this growth. After being lifted the bulbs should be laid out on layers of newspaper or brown paper in a dry outhouse (not in the sun). They may be divided if they separate easily, or can be left until the leaves and roots are quite dried, when these can be removed, and the bulbs separated and placed in bags or boxes with the names of the kinds affixed. They may be planted fresh at any time during the autumn, and fair flowers of the later sorts may be obtained from bulbs planted in January, or even in February, but to get really good results and a proper development and multiplication of the bulbs, they should not be put in later than August or early in September. I usually plant as many of mine as I can plant early in August. The foregoing remarks apply, of course, more particularly to the general cultivation of Daffodils, but they have an especial bearing upon the subject of the article, for all.

Hyacinths and Forsyth have a much better chance of success if planted early and brought on in as cool an atmosphere as possible. Nothing is more spring-like or refreshing than a few specimen glasses of these beautiful spring flowers in the earlier weeks of the year. I have only a small coal greenhouse, and cannot spare much space for bulbs, but I manage to obtain a continuous series of blooms from about February 1st until the antelope species begin to flower, and these, of course, almost last to June. Had I possessed a warmer house as well as a cool one, I might have had Daffodils in my room for nearly five months without a break. There is, however, this advantage in your patiently slight forcing in a cool house—viz., that the bulbs do not appear to suffer much, whereas, if strongly forced, they are not worth much afterwards. In my case, forcing does not do bulbs any good, and it is, therefore, best to use the cheaper sorts, which are quite as useful for all practical purposes. For indoor (as well as outdoor culture) the bulbs should be planted in August or not later than the beginning of September. They should be put into pots or fairly deep boxes, and these should be placed out-of-doors on a hard bottom (gravel or ashes, not earth), and covered with a thick layer of ashes or Cocoa-nut-lime; either of these will do, but the latter is very much cleaner for use with pots that may have to come into the house. The ordinary rule for planting Daffodils is to cover them with soil to the depth of one and a half times their own length from collar to base. This I have always followed with very good results; but Daffodils for forcing should not be covered with more than half an inch to an inch of soil. When the bulbs begin to sprout vigorously it

may be taken for granted that the pots or boxes are full of roots, and they may then be removed into a cool greenhouse either in succession or altogether. If the sorts have been planted for succession they may all be brought in at once. Almost all the species may be grown in pots and forced more or less readily, with the exception of the Pheasant's-eye Narcissus and the double form commonly called the Gardenia-flowered Narcissus, and certain sorts, perhaps, that will not flourish except in Grass, as moschatus of Hawth, pallidus praecox, etc. The following list, however, may be found useful, the bulbs in each section are placed in the order of succession:—*Yellow Trumpets*: Golden Spur, spurius, ohrallaris, King and Queen of Spain, maximus, Emperor. *Bicolor Trumpets*: princeps, Horstiehl, Empress, Victoria, grandis. *Incomparabilis*: Queen Bess, Sir Watkin, Stella. *Barri vars.*: Barri conspicuus, Flora Wilson. *Leedsii vars.*: Minnie Hume, Mrs. Langtry. *Barbidgei vars.*: John Bain, Barbidgei, Ellen Barr. The variety ornatus of Narcissus poeticus will force well, and the Jonquils, also, can be grown in pots. Almost all the above can be obtained at a very low rate, and the expenditure of a few

and it is, of course, well known that many species can be grown in rooms in bowls filled with water and fine gravel, or with a damp mixture of Cocoa-nut fibre and charcoal. The regular growers are unable to issue their catalogues, as a rule, before August, and, therefore, those who have not their own stocks to lift from should send in their orders as soon as possible after they have received them.

W. W. FOWLER.

Peppert Rectory, Henley-on-Thames.

NOTES AND REPLIES.

Fuchsia fulgens.—You were asked, I noticed, a question some time ago about *Fuchsia fulgens*. Your querist may be interested to know that if cuttings of it be struck in the summer, given a 3-inch pot to winter in, kept near the glass, and not too liberally supplied with water, they are pretty certain to flower the year following. I had one of such last year, hardly a foot high when it showed flower buds, in a 4-inch pot, and the twelve or fifteen long scarlet blossoms had a good effect, hanging down on the ample foliage of the plants. If large, old plants of this *Fuchsia* be

Pottebakker, Keizerkroon, crimson and gold, Crimson King, Ophir d'Or, yellow, Rose Gris-de-la, piak, and Artus, deep scarlet. These are single. Of doubles you can grow Duc Van Thol, deep crimson, very full, La Candeur, white, Rex Rubrorum, bright scarlet, Yellow Tournesol. Treat in the same way as Hyacinths in pots.]

VEGETABLES.

TEMPERATURE FLUCTUATION AND ITS INFLUENCE.*

PERHAPS at no time could the influence of the alternate cold and mild weather be so easily discerned in vegetation generally as this year. Those accustomed to plant their Potatoes early, so as to have them off the ground in readiness for something else, are the greatest sufferers. Potatoes planted late, and which did not appear above the ground line while frosty mornings were the rule, escaped. The craze, however, with most growers to have the home-grown tuber at the earliest date places many in an awkward position when frost has cut off the tender tops. The influence of shelter, either from walls, hedges, or trees, has been very marked this spring. In my case it has not been the south border, so often looked upon as that affording the first crop, that is best; east and west aspects have been distinctly advantageous. On a west border, sheltered somewhat by trees and a lofty wall, Potatoes were almost unharmed, while on a south border, and a more open site, they were hopelessly damaged by the prevailing May frosts. The extreme cold caused much loss of early sown seeds, especially those of a tender nature, and even hardy kinds gave a poor return from first sowings. Even the Spinach suffered this year. Peas came up very irregularly from the effects of chill, and quite a long chapter could be written bearing on the effects of the cold. The change from extreme cold to mild weather, accompanied by rain, was even more striking, nothing, perhaps, showing this more plainly than the mowing machine, or the daily cutting of Asparagus. The cutting of this spring vegetable has revealed a wonderful range of difference from day to day, the produce of some mornings being quite two-thirds more or less than on others. This was not only the case in the earlier part of the season, but in June, when the temperature declined so rapidly, the growth of Asparagus became as sensitive as the thermometer itself: indeed, there would seem to be almost the same graduation in its rise and fall. Flower garden planting has never been carried out under better conditions than this year—that is, in those cases where late planting necessarily follows winter and spring bedding—as the ground was thoroughly moistened by the frequent showers and the steady rise of temperature combined to make the conditions very suitable compared with some years, when so much time is spent on watering and with so little return. S.

NOTES AND REPLIES.

Tomatoes in pots.—I have twenty-four nice strong plants about 10 inches high in 6-inch pots. I want to grow these in my greenhouse. My house is only 8 feet by 6 feet, span-roof. It gets the sun all day from all quarters. Never having grown Tomatoes before, a few hints will be useful. What size pots shall I now put them into? Do you recommend wire or stakes for training?—LORIE APPLE.

[Pot-culture throughout the season has advantages, not the least being that all available warmth from the sun strikes the roots as well as the leaves. Pots not less than 10 inches across may be used, and into these you ought to shift your plants at once. If smaller it is difficult to water the plants often enough when in full growth, unless the roots have soil heaped to run into. Allow enough room for the plants—quite 15 inches apart—and they should be trained single stemmed, not too far from the glass. Pinch out all the shoots that spring from the axils of the leaves. Air may be given in abundance. A close, damp atmosphere is most detrimental at any time, and is sure to bring diseases. Good stout stakes answer well for training them to.]

Coleworts.—Make a sowing forthwith of the Rosette in shallow drills, 12 inches or 15 inches apart. Sow firmly, as if the plants

Empress Daffodil forced. From a photograph by Mrs. Stuart Rickman, Arborfield Grange, Berks.

shillings will be amply repaid. The clearest species is Victoria, but this is almost the best species for forcing, and it is being so largely grown that the price is rapidly diminishing. Another Daffodil that might have been mentioned is J. B. M. Camm, one of the most beautiful of all, a Trumpet Daffodil with a white perianth and sulphur trumpet, changing to pure white; but this and others I have omitted as being too expensive. I have had no experience in growing smaller kinds of Daffodils, but I understand that the following may be had in bloom in January: N. minimus, minor, nanus, and cyclamineus, and that the White Hoop Petticoat Narcissus (*Corchularia monophylla*), if potted in almost pure loam; well kept moist, may be had in bloom shortly after Christmas. I have seen the beautiful little Narcissus triandrus albus (Angel's Tears) flourishing in a pot in a greenhouse, although this might hardly be expected from its natural habitat.

In conclusion, it may be well to say that a greenhouse is not a necessity. Provided the bulbs are well started out of doors, they will come on well in a room if kept near the light.

placed out-of-doors in the summer, they will generally form flower-buds at the points of their shoots if the site be sunny and warm.—IRISH READER.

Brugmansia arborea.—I should be much obliged for any directions for growing *Brugmansia arborea* well? I have had one in the heated greenhouse for several years, and it has not bloomed before, but is doing so now. It is a yard high. What sized pot should it be in? I have seen a picture of one growing in the garden in Gloucestershire. Would it do outside so far north as this?—FLORA.

[Your best plan, if you have room, will be to plant it out in a cool greenhouse, using some good loamy soil, leaf-mould, and rotten manure, giving plenty of drainage. After blooming the plant should be pruned every year. Allow it to get dry at the root before pruning it. Whilst in flower doses of either liquid-manure or some artificial stimulant should be given.]

Early single and double Tulips.—Will you kindly give me the names of some early forcing single and double Tulips as grown by the market gardener for the London market? There are lovely yellows, pinks, and crimsons on firm, erect stalks, and they last a long time in water. Do they require any particular treatment?—F. H. P.

[You cannot do better than get white

have to remain long in the seed-bed they get spindly. Plants from this batch, if set out as soon as fit, will form nice firm heads towards early winter, and they can be set out fairly close, 12 inches to 14 inches apart being sufficient. A later sowing, made about the middle of July, should come in useful for filling ground that may have been cleared of early Potatoes or Broad Beans. Keep the seedlings dusted occasionally with wood-ashes and a little slaked lime. This will generally drive away the fleas that often attack the Cabbage tribe during hot weather, though, up to the present, summer weather is certainly conspicuous by its absence.—J. M. B.

Vegetables at the Drill Hall.—An effort is now being made to induce the council of the Royal Horticultural Society to extend its patronage to vegetables in the same wide degree as it does to plants, flowers, and fruits, by having at least one of its many fortnightly meetings each year at the Westminster Drill Hall, James-street, devoted to a special vegetable exhibition. At present, at any of the society's numerous shows and meetings vegetables are rarely seen, and even then are rather endured than encouraged. That is not fair towards a section of garden products that is of the highest importance to the entire community. Generally, in all good gardens vegetable culture takes a foremost rank, and in connection with local or provincial shows vegetables get material space and encouragement, and always prove most attractive. It is hoped that the council will be induced to give to vegetables that space and encouragement they merit by having special exhibitions of them alternately in July for summer, and in October for autumn kinds.—A. D.

Summer treatment of Asparagus for forcing.—I am convinced that the major part of the failures with forced Asparagus arises from the bad treatment in summer. The best roots, I consider, are those from five to ten years of age, and then, if they have been well cared for, they are in their greatest vigour. Everyone who needs roots for forcing should sow seed every year in proportion to his needs. When the plants are strong enough to cut from, this should not be too severe, and that which has to be forced the following winter should not be cut from, allowing all the growths to remain to strengthen the roots. In this way good crowns are formed. Aided to this, the strong growths should be protected from the wind. Asparagus is much benefited by giving it either liquid-manure-water or two or three applications of a quickly soluble manure in wet weather. I am convinced that the earlier the growth ripens the more easily can Asparagus be forced. It is essential to have good roots.—J. CROOK.

Preparing for summer heat.—No time should be lost in seeing that everything is in working order for watering, such as hose, water barrels, and such like, nor should material that is suitable for mulching be neglected. Should this consist of long strawy manure, this should be put together and moistened to make it hot. It is of the utmost importance that a good mulching be given to Peas, Runner Beans, Cauliflowers, and Lettuces—in fact, all vegetables—where possible; also fruit-trees, applying it early before the moisture is drawn out of the soil. Land that is deeply worked and given plenty of manure, mulching where possible, seldom needs much water. Rotten leaves, mowings from lawns, in fact, any green material, help to keep the soil cool and moist. Where a continued supply of Lettuces, Spinach, Turnips, Radishes, and salad of all kinds is needed, then it is a good plan to supply work a shady border (not one overhung by trees), and give abundance of manure, sowing where the plants are to remain. Cauliflowers need a cool, deep, holding soil in summer. Whenever there is room, Brussels Sprouts and such like should be got out before the hot weather comes on, as in this way they get established without having recourse to watering.—F. A.

French Runner Beans.—There is a partiality among some cultivators for the French type of Bean over that of the ordinary Scarlet Runner. Sometimes the dwarf French Bean surpasses the Runner in point of crop, though not always in continuity. It is in cold

and exposed places where I have seen the advantage of growing dwarf Beans in preference to Runners, because the latter suffer from gales, while they pass over those of lower growth without much effect. Some prefer the French Bean by reason of its more delicate skin and flavour. Where this is the case, and the conditions suit the growth of trailing varieties, the French Runners are to be strongly recommended. Veitch's Climbing is a very good kind; its pods are similar to those of the Canadian Wonder in size, length, and colour. Epicure I have grown for forcing for the first time this year, and the results are so satisfying that it will be more freely sown in future, both for forcing and early gathering outdoors. This has a distinct and solid pod. As the time is now opportune for sowing Beans outdoors, those desirous of proving any fresh kind should do so at once. There are, beside these two climbing kinds, several others more or less distinct, but the above are kinds which can be recommended.—W. S.

GARDEN WORK.

Conservatory.—Cactuses are showy and interesting plants. Several species will be in flower now. *Cereus speciosissimus* when planted out will grow to a large size and bear hundreds of flowers, but it should be supported with strong stakes, as it is a troublesome plant to train. The dwarfier species, *Echinocactus*, *Opuntia*, *Mammillaria*, *Melocactus*, and others, are more easily managed, but they do not make so much show. These should be grouped together. There were many good collections years ago, but they to a large extent disappeared, for the time being only, and are now being sought for. Those who want to see a good collection now should visit Kew. Most of the species are improved by placing outside in summer when growth is finished; the full exposure ripens them, and when moved indoors in September they are all the better for the outing. The Aloe family is included in the same general term of succulents, and requires much the same treatment as the Cactus tribe. Both of these and various other succulents are sometimes planted out in summer, and if skilfully and tastefully grouped they are not without interest. Years ago we had a cold conservatory, where the back wall was covered with Myrtles. It was always green, and at this season, when the plants were in flower, the wall was a very effective feature, and one could always cut a handful of green sprays to mix with flowers. We still grow Myrtles in pots, and our plants are now just in bud, and will soon be white with blossom. The flowers do not last long, but they are sweet, and the whole appearance of the plants suggests homeliness. Tree-Carnations should now be in the flowering pots, and placed on a coal-ash bed in the open air. The watering should be in careful hands, as a water-logged plant may as well be thrown on the rubbish heap. The old-fashioned Cockscorn, when well done, generally attracts attention, and a group mixed with Ferns gives variety, and the more of these special features in the house the better. The same may be said about Balsams, though of late years they have not been so popular as they were, partly because they are of no use for cutting.

Stove.—*Acalypha Sanderiana* is easily propagated from young side shoots in bottom-heat, kept close. Young plants should be shifted on and encouraged to grow freely. They will not succeed in a low temperature, though they may be moved to the conservatory when in flower for a time; but the plant wants heat to develop the flowers. *Allamandas* and *Dipladenias* will now be coming into flower, and will produce a gorgeous effect. The Night-blooming Cactus is an interesting plant to those who visit their houses after dark, and the flowers must be seen at night if at all, as they soon fade when daylight comes. The Sultan's Balsam (*Impatiens Sultani*), easily propagated from cuttings and seeds, makes a bright little table plant in a 5-inch pot, and looks well in association with *Rivina humilis*, *Caladium argyrites*, *Ficus radicans* variegata, and *Cocos Palms*. *Jasminum gracillimum* should, if possible, be planted out

for the sake of its sweet flowers for cutting at all seasons.

Ferns under glass.—Many of the stove or tropical Ferns will do now without heat. The *Gymnogrammas*, if the nights continue cold, must have a little artificial heat at night, or their delicate fronds may suffer. Ferns will now be at their best, and the small plants will do very well in a cold-pit if kept fairly close and shaded from hot sunshine. Young seedlings in boxes or pans should be pricked off into boxes as soon as they are large enough to handle. Trade growers take them out in little tufts, as their object is to produce saleable plants speedily. For the same reason, in shifting into 5-inch pots (which is the market pot) two plants are frequently placed in each pot. Occasionally a green kind and a variegated kind are placed in the same pot, and very pretty effects are obtained when the two blend together. For house decoration we have often planted seedling Maiden-hairs and other Ferns and Moss on the tops of the pots in which Palms and other specimen plants are growing, the effect being enhanced thereby, as, without injuring the Palms, a dressy appearance is given to the only unsightly spot about the plant. It is a good plan, in addition to as many large specimens as can be accommodated in the space allotted to Ferns, to grow a large number of smaller plants. There is a large demand now for small Ferns in thumbs and pots of a slightly larger size. Mosses, also, and the pretty little *Madra* Grass are always useful. There can never be too many small, neat plants for decorating the rooms. The difficulty, if there is a difficulty, is in having sufficient variety, as no one likes to see the same plants too often.

Late Grapes.—The weather for some time has been dull and the nights cool, and it has been necessary to use a little fire-heat. It is always a mistake to stop the fires before the weather is settled, or if we get a short spell of hot weather, and then the cold wave returns, recourse should be had to fires again. If the berries of *Alicante* or *Gros Colman* are not sufficiently thinned, go over the bunches and relieve the crowded places. *Muscats* should have a little fire-heat until finished, and the lateral growth should be kept well in check if the amber tint so much esteemed is to be seen on the berries.

Window gardening.—More attention is being paid to outside window gardening than inside at present. A few well-hardened Palms may be used for a time as a background. One of the most effective plants for the back of window-boxes is the Japanese Grass (*Eulalia japonica variegata*). It is light and elegant. It will look well grouped in the corners of the boxes outlining the window. In connection with *Clematis Jackmani* the effect is very good and will continue for some time. What one wants is more originality. Within a short distance of where I am writing there are many windows decorated with flowers all in the same way, and the effect is exceedingly monotonous.

Outdoor garden.—There is a good deal of staking and tying to do now, and promptitude is necessary in keeping pace with the work, as if a plant is blown over by the wind it is never quite the same thing during the same season afterwards. Standard Roses should be specially looked to, especially if wooden stakes are used, and even with iron stakes the trees, with the weight of blossom and foliage, sometimes give way. Those who want fine flowers thin the buds of the Roses and Carnations, and as regards the Roses it is well to thin the buds somewhat, as it tends to make the succession more constant generally. When the buds are not thinned the first heavy head of bloom exhausts the plants, and then there will be no more flowers till the autumn. The only really perpetual Roses are the Teas and China. Those who have not yet sown Wall-flowers and other biennials should lose no time, as when sown late the plants are too small to flower much. Flowering shrubs, such as *Lilacs* and *Guelder Roses*, should have what pruning is necessary immediately after flowering.

Fruit garden.—When *Melons* are grown in frames, if the heat in the bed has declined, it may be necessary to surround the bed wholly or partially with linings of warm manure.

Early Melons are to a large extent now grown in low, span-roofed houses, and fire-heat is used, and the result is generally more satisfactory, as the temperature is more under control. Melons, even more so than Cucumbers, require a steady root warmth, with an atmospheric temperature of 65 degs. to 70 degs. If the roots are right the plants should not require shading at any time. A little ventilation early in the morning to let out the vitiated atmosphere, to be increased as the sun gains power, will keep the foliage robust and free from red-spider. Keep the young wood of Peaches under glass neatly tied in, and do not crowd in too much wood. Give liquid-manure freely after the stoning is finished till there are signs of ripening; but if the borders are heavily watered after the fruit begins to ripen, the flavour will suffer. The Cape Gooseberry (*Physalis edulis*) is a pleasant flavoured little fruit, scarcely so large as a Gooseberry. We used to grow it years ago against the back wall of a Peach-house, where it fruited very freely. It will succeed under the same treatment given to Tomatoes, both inside and against a warm wall in the open air. It may be raised either from seeds or cuttings. It will be necessary to still give attention to insect pests on the trees.

Vegetable garden.—The crops have made rapid progress since the showery weather set in, and the weeds, as they always do under such conditions, have obtained temporary mastery over the gardener who is short-handed; but a supreme effort must be made to clear them off before they seed, otherwise they will give trouble in the years to come. Among the routine work now will be planting out Winter Greens on every available spot. Sow an early kind of Cabbage to form Coleworts in winter. We have sometimes sown Tom Thumbs Savoy for the same purpose. It is hardier and is excellent in flavour. Continue to plant out Celery and Leeks in trenches or otherwise. Give the final thinning to Beet and other root crops not yet attended to. Beet transplants well if carefully done, so that the long root is inserted straight in the ground. Turnips sown now will not bolt, neither will Endive, which should be sown in rows 15 inches apart, and thinned out to the same distance between the plants. This refers only to the present. Later sowings will be better transplanted. Lettuces may be treated in the same way. We have had no hot weather yet. When it comes, Lettuces and Cauliflowers should be mulched. Earth up Potatoes. No more Asparagus should be cut, and the beds should have nourishment. E. HOBDAV.

THE COMING WEEKS WORK.

Extracts from a Garden Diary.

June 30th.—Planted out *Humea elegans* along back of herbaceous border. Pricked out choice seedling hardy Primulas and Auriculas in shady border. Put stakes to Carnations in beds, and gave a top-dressing among the plants of good loam and old manure. Finished potting *Chrysanthemums*. The plants are securely staked in rows easily accessible on coal-ashes. If black-fly appears Tobacco-powder will be used, and earwigs will be watched for.

July 1st.—All old Fuchsias have been planted out. Younger plants are trained up for conservatory. The old plants are pruned back rather hard, and the young shoots make excellent cuttings, which, when rooted early and kept moving during winter, make useful early-flowering stuff in 5-inch pots, or may be grown on into specimens. Sowed Forget-me-nots and Pansies in cool borders. We shall cut no more Asparagus; the beds have been cleared of weeds and top-dressed with nitrate of soda.

July 2nd.—Sowed second early Peas and Ne Plus Ultra dwarf French Beans. Top-dressed Cucumbers in frames with good loam and old manure and a little soot. Liquid-manure is given to Cucumbers and Melons in bearing now. The fruit on succession Melons is set when the pollen is dry in the forenoon. The frames are closed early after syringing on bright days. Watered the inside border of late vineyard and Peach-house; a little stimulant was in the water.

July 3rd.—Liquid-manure is given to Sweet Peas, Hollyhocks, and herbaceous Phloxes.

The lateral growth of Vines is kept well in check in mid-season and late houses. Gave a further thinning to the young wood of Peaches on walls, and removed a few more of the young fruit. One tree in an exposed position had blistered leaves. These were picked off and the trees dressed with Tobacco-powder, and afterwards syringed with Quassia extract. Mulched Tomatoes under glass with Moss-litter-manure to save watering.

July 4th.—*Verbena*, *Heliotropes*, and *Ageratum*s have been pegged down close. Where *Rosa*-beds are not mulched the surface is kept loose by frequent hoeing. The loose soil acts as a mulch and keeps in the moisture. Cut down one long row of *Globe Artichokes* to induce late growth. To have fine succulent heads we feed liberally. We are looking after early Strawberry runners for forcing. They are laid into small pots till rooted. All through the season the plants are kept in an open situation and confined to one crown.

July 5th.—Shifted on a lot of *Asparagus Sprengeri*. This is a very useful decorative plant, charming in baskets. Potted on *Cyclamens*. The compost is one-half best turfy loam, and remainder old manure, leaf-mould, peat, and sand. Pots are carefully drained. Plants will be grown in cold pits during summer, freely ventilated, and lightly shaded when the sun is bright. Sowed more Lettuces. Every spare minute is given up to hoeing. Leaves are broken down over Cauliflowers to keep the sun from the heart of the plant. Celery is planted in succession as ground becomes vacant. Filled frame with cuttings of double-flowered Arabis.

BIRDS.

Love-birds (*Peter*).—These birds should be fed upon boiled Maize, Canary-seed, and Millet. Give them as large a cage as possible, which need not be provided with nest-boxes, as these birds prefer to use a hollow log or a Cocoon-busk as a resting place. These should be hung up near the top of the cage, and have the aperture, which should be at one end, turned towards the light.

BEEES.

STARTING BEE-KEEPING.

HAVE often thought I should like to go in for Bee-keeping, and would be very glad if, through your paper, you could give me a few hints as to how best to begin. I have a garden in which I could grow suitable flowers, and there are a good many round about.—J. S.

[In starting Bee-keeping an important matter to consider is the sources of the honey supply in the particular district. Some localities yield well through May and during the early part of June, but in others little is gathered until the middle of that month. Then, again, in the north not much honey is gathered till the Heather is in flower. Still, it should be remembered that Bees travel long distances in search of stores, a radius of two miles from the apiary being visited by them. It is not so much the flowers of the garden that Bees depend on for supplies, the great bulk of the honey stored in the hive being obtained from fruit-tree blossoms, Clover and Bean fields, white Thorn, Lime-trees, and Heather, while the various kinds of Willow afford abundance of pollen in the early spring. The best way of beginning at this time of the year is to obtain swarms from some Bee-keeper in the neighbourhood. It would be well for you to arrange to have the swarm or swarms sent home on the evening of the day on which they leave the parent hive, as comb is very quickly built by a strong swarm, and if the hive is moved while the combs are new and tender they are liable to break away and cause confusion; and, again, if the swarm is left any length of time before removal to fresh quarters many Bees will be lost. It is well to feed a late swarm for the first fortnight or so, that all may be kept in a state of progress, and comb quickly built out. The feeding, however, must not be over-abundant, or the cells may all become full of stores, to the exclusion of brood.

The frame-hive is far in advance of the straw skep; if, however, you decided to keep your Bees in straw hives, these should be of large size and flat topped. Upon these can be worked best those species in which the Bees readily store the surplus honey in beautiful form. These

section-boxes hold just one pound of comb honey each, and being of very inviting appearance when nicely finished are easily disposed of. But if you wish to work for extracted honey you will find frame-hives of great advantage, as from these the combs can be removed as filled by the Bees, the honey extracted, and the combs returned to the hive to be refilled. A frame-hive to be occupied by a swarm should be furnished with comb foundation, in strips fixed to the underside of the top bars, as guides to the Bees to work out the combs within each frame. This comb foundation contains sufficient wax in its projecting walls to enable the Bees to completely work out the cells. When a swarm from the hiving skep is introduced to a frame-hive the latter should have a cloth or newspaper spread in front of it, one edge being brought over the alighting-board, and the front of the hive raised from the floor-board about 2 inches, being supported by a stone or wedge. The hiving skep should then be taken by both hands, and by a sharp and sudden movement the Bees shaken on to a sheet or newspaper. In a few minutes all the Bees will have entered the hive and formed a cluster. The day after hiving, the frames should be closed up by means of the division-boards, and all made warm and comfortable for the encouragement of honey storing.—S. S. G.]

LAW AND CUSTOM.

Notice to quit.—I took a cottage, cow-house, pig-stye, and two acres of land, on a yearly tenancy from Sept. 29, 1901, to pay rent half-yearly. I received notice on March 25 last, to quit on Sept. 29 next. Am I not entitled to a year's notice, expiring with a year of the tenancy? Does the payment of rent half-yearly affect the issue?—W. T.

[Have you a written agreement of tenancy or not? If you have not, then, supposing that you took the place at so much a year, the tenancy is yearly, and is not affected by the fact that you pay the rent half-yearly. The holding is within the Agricultural Holdings Acts, and so if there be no written agreement as to notice, a year's notice terminating with a year of tenancy is necessary; and this means that the notice you have received is bad, and that to get you out at the earliest moment, a new notice to quit on Sept. 29th, 1903, must be served on or before Sept. 29th next. But if you have signed a written agreement, any notice stipulated in that agreement will be sufficient, even if it be only a month's notice.—K. C. T.]

Agreement for working nursery ground (*A. R. B.*).—Probably you imagine that you are a yearly tenant, and that if this agreement were invalid because of the absence of a witness you would remain a yearly tenant free from any of the terms imposed by the agreement. But if this be your impression you are very much mistaken, as you are not a tenant in any sense of the word, and if this agreement were invalid the owner of the ground could turn you out at a minute's notice. In reality you are, by virtue of this agreement, engaged for two years to work this nursery ground at a specified and unvarying weekly wage. The owner of the ground is to pay for such additional labour (over and above your own work) as you and he shall mutually agree, and he is to find the money to pay for such materials as are necessary. He is to take all the proceeds of sales of produce, etc., until those proceeds amount to the sum of the following matters: a fixed amount termed rent, also the rates and taxes on the holding, and the monies laid down by him and 7½ per cent. interest thereon. After these charges have been met you are to take the proceeds of such produce as there may be until rent again begins to accrue, when your remuneration will be limited to weekly wages until the accruing charges are paid, and after that you will again take the proceeds as before. It is implied that there shall be quarterly settlements, as the rent is apparently to be calculated by the quarter. I can see very much that is vague in the agreement, and there is room for endless disputes; but, although it contains no express power on the part of the owner to appoint a receiver, or, as you term it, to "put a trustee over the place," he is quite entitled to do this. The agreement stipulates that the owner is to receive all monies from sales of produce until his claims are satisfied. It does not even say

VEGETABLES.

LATE-PLANTED CABBAGES.

Most gardeners plant their Cabbages out early, so that they become well established before cold weather sets in. Last autumn I sowed that this haste in setting out the cabbage crop is not of so much importance as I once thought it to be. It came about in this way: A plot of Strawberries not more than two years planted was not particularly satisfactory in fruiting last summer, but hopes were raised that at least one more crop would be had. As the autumn advanced, however, the plants, instead of improving, became still more unsatisfactory, and finally it was resolved to clear them off and replant the ground with Cabbages. This was a November. The main crop of plants had already been put out, and had until then and since required making up. The November-planted stock took kindly to their new quarters, and grew away almost without the loss of a plant, and in spring the bed was much the best in the garden, the growth being so uniform and even. A good many bolted in the first planting; in the November bed not one failed from this cause. It is only fair to say that the first Cabbage was not cut from this bed, but the earliest was from another sort which did not form part of the November planting. What is equally remarkable is that these later Cabbages were from the same sowing as for the main crops already referred to. In this instance the smaller plants remained after the available ground had been filled up, and possibly this explains somewhat their greater uniformity in spring time. The ground was not dug after the Strawberries, but simply hoed and raked over, so as to remove the Strawberries and to have the surface clean and smooth. The firmness of the ground would be favourable, but as Onion-beds usually afford a site for the August plantings, the difference in soil firmness did not make so material a difference. Such instances are interesting, and in some degree instructive, particularly in small gardens.

W. S.

LETTUCES.

There should be no difficulty in securing an abundant supply of Lettuces this season, provided young plants escape slugs, which in wet weather prey so severely upon them. To restrain these pests, not only should dressings of fresh soot and slacked lime be freely applied, but plants should often be looked over in the evening, as it is just then that slugs are out feeding. Provided such troubles of early days are overcome, and they are usually so with ordinary care, it is still to be said in relation to Lettuces that whilst they like ample moisture they also like ample warmth to cause them to grow quickly and become sweet and crisp. Still further they are much less needed or appreciated when the weather is wet and cold. Whether, then, presented alone, clean, cool, and crisp, or with other salads in mixed form, there is hardly any more acceptable variety

summer food than Lettuce affords. It is also not a matter of moment whether the Lettuce be of the ordinary Paris White Cos type or of any good Cabbage variety, if both be sweet and crisp. But many of the latter forms are very bitter, and acceptable as such taste may be with Endive, it is not so desirable with Lettuce. Generally any good Cos type, if quick grown and well blanched, gives sweet leafage. A common plan in gardens, and particularly so in small ones, is to put out just one or two breadths of plants only, and often much larger ones than existing necessities require. The result is considerable waste. It is far better to sow once about every three weeks, and thus have small breadths to put out just so often. By that plan it is seldom that there is any lack of good Lettuces in a garden from May till October, and much longer if some cold-frames or south borders can be devoted to them in other months.

A. D.

NOTES AND REPLIES

Stopping outdoor-grown Tomatoes.

—One of the errors into which many fall in growing outdoor Tomatoes is that of continuing the leaders after this date instead of stopping them, and thus throwing all the energies into the fruit already set. By some the stopping of the growth in July is not regarded with much favour, but from experience I can say that one is assured of at least a few bunches of ripened fruit fairly early. This is not always the case where the leader is allowed to grow. In how many cases do we not see an abnormal amount of foliage on plants out-of-doors towards the end of a season, with very little fruit set? It is better, therefore, to make sure of the early bunches by stopping the leader now.—TOWNSMAN.

Endive.—To have an abundant stock of plants to put out in August and September sowings of Endive should be made at once, and again a couple of weeks later. Sow in shallow drills thinly 12 inches apart, as in that way the plants get much more room, and can be stout and well rooted when lifted, ready for planting out. Ordinarily it is well to plant on warm borders that slope to the south, following after some early crop, previously well manured, as such ground should do Endive well. Where such borders are not available it is then well to make sloping beds, 4 feet wide and facing south. A sloping surface enables water to flow away readily from the plants when heavy rains fall in the winter. If for the Dwarf Curled, rows 12 inches apart, and the plants 10 inches apart in the rows, suffice. But the coarser-growing broad-leaved Batavian variety should be in rows 15 inches apart, and the plants quite 12 inches apart in the rows. These can later be blanched by tying up the leaves, as is done with Cos Lettuces. The curled plants can be blanched by covering them.—A. D.

Sowing late Peas.—From repeated experiments we find June 1 quite late enough to sow for main crops of Peas, from which we always keep gathering as long as the weather remains mild enough for them to make

any growth. Last year we sowed our main latest crop on June 2 in trenches, well manured, as if for Celery, scattering the seed thinly all over the trench, so as to make a broad row. The plants were soked as soon as high enough, and the soil between the rows, which were 6 feet apart, was covered with long stable-litter to retain moisture, the soil being very dry at that date. By means of copious waterings a rapid and luxuriant growth was the result, and they produced a fine crop, which lasted as long as green Peas were procurable out-of-doors. The sorts which we grow principally are Ne Plus Ultra and Clampton of England, both kinds difficult to surpass for quantity, quality, and long continued bearing. Ne Plus Ultra is an especial favourite in the kitchen for its deep green colour, and if confined to one sort I should prefer it to all others. For the late tall Peas good supports are necessary, and I find Chestnut branches much more durable than Hazel, as they are perfectly sound the second year, while Hazel only lasts one season.

Cauliflowers clubbing (S. D. D.).

—Where clubbing is prevalent preventive measures ought to be taken. Sometimes it is caused by the grub of a small beetle or weevil, and occasionally the maggot of a midge or fly is responsible for the mischief. A free use of soot and lime, forking them into the surface of the bed before sowing the seed, has a deterrent effect, and so also has sand soaked in petroleum, the surface of the bed being dressed with this every week or ten days. Before planting examine the underground portion of stem of each plant, and cleanly cut away every small excrescence or wart there found, following this up with the oil-fashioned remedy of pulling the roots of all the plants. Form a puddle with clay, soot, lime, and water, a wineglassful of petroleum being also added with advantage, and drag the roots through this so as to thoroughly coat them and the lower portion of the stems with the puddle. Thus treated, they seem to feel the check of removal less than when not puddled, and are seldom interfered with by either maggot or wireworm afterwards. It is on stale, indifferently cultivated ground that grubs most often gain the ascendancy. You will do well to do all you can towards promoting a vigorous growth by way of prevention of club root. Newly slaked lime at the rate of 1 bushel per rod ought to be forked into the surface of the previously well-manured ground, and after the plants have been put out, all being carefully fixed, clear water should be given for a time, or for the first week or so, afterwards giving liquid-manure frequently. Nitrate of soda, or that in mixture with superphosphate of lime, dissolved at the rate of 1 oz. to a gallon of water, would be the best form of fertiliser for the purpose. Apply at first round the plants, but when the latter are growing strongly draw mould up to the stems and pour the liquid-manure freely along the furrows. Petroleum is one of the best insecticides ever discovered, and in extreme cases of clubbing we would advise soaking sand in it and mixing the litter freely with the soil in which the Cauliflowers are planted.

PLANTS AND FLOWERS.

INDOOR PLANTS.

GREENHOUSE FLOWERS IN LATE SUMMER.

It often happens that greenhouses, which, during May and June and the early part of July, exhibit much beauty, begin to show signs of falling off towards the end of July and August, a state of things which is mainly brought about, I think, by a failure to keep up a supply of young plants to take the place of those that have begun to fail. To maintain vigorous plants, one should always have in reserve a sufficient and varied assortment to last one right into the autumn, and this can very easily be done by preparing what is required now. There is no particular expense attached to this, as the propagation from cuttings and the raising from seed of some of our best known plants can at once be attended to. For example, cuttings of Fuchsias and Zonal Pelargoniums should at once be taken and grown on for blooming at a specific period, say, the middle of August. This, of course, will necessitate the removal of all flower buds until the near approach of that time, keeping them in the meantime in cold frames, and thus, with the change of temperature by their removal into the house at the date referred to, they will quickly burst into bloom and keep the house gay for weeks to come. I have always been struck with the absence of annuals from greenhouses in the autumn, and never could understand the reason why, for instance, the pink and white Rhodanthes are grown only in spring by most people. Seed sown in June will furnish many pots of blossoms in July, and there is less likelihood of their dumping off when young, as they sometimes do when sown in February and March; or, again, what can vie with Mimulus grown specially for blooming in August? Petunias are free-growing, and both double and single are easily raised in this way, or cuttings of approved sorts readily strike and make handsome plants if grown on in loam or leaf-mould, pinching them back to give them shape. I believe that some people, however, still are under the impression that double sorts can only be propagated in this way, but this is not so, as quite 60 per cent. of the plants produced from a packet of seed of a double sort come true. Fuchsias, as I have said, one never tires of, they are always interesting, and, to prepare a batch of plants for blooming a few months hence, one has but to strike the cuttings this month, prevent them from blooming by taking off the buds as they appear, and then, a few weeks before they are wanted in bloom, give them a stimulant. Balsams are wonderfully attractive in the spring; they are not less so when blooming in August, and to have them at that time is only a matter of sowing the seed, the finest trusses of bloom resulting from plants that have been given the most liberal treatment, this consisting of a rich compost of loam and partly rotted cow-dung, with leaf-mould added. That fragrant flower both for indoor or outdoor growing, the Heliotrope, can be brought on for flowering at any time of the year. Cuttings struck now will be in their prime in August, or they may be further retarded for late blooming by a removal of buds as they form. That oft-seen window plant, *Franca ramosa*, is a most useful greenhouse plant, and young ones now ready for shifting into 5-inch pots will be in bloom in August, and though the flowers are not by any means brilliant, they are produced in great quantities on their wreath-like stems and, what is of importance, last a long time. *Seizanthuses* must be grown and bloomed to be fully appreciated; they are most delightful half-hardy annuals, and when grown in pots and flowered in the house, as they should be, they make compact plants crowded with blossoms. Where young plants can be had they should now be potted on. If, besides all these, one desires attractive foliage, what can compare with the richness of *Coleuses*? That they may be raised from seed and grown with great rapidity if kept in a warm greenhouse, where the atmosphere is charged with moisture, is well known; but it is half the trouble to propagate from seed

now that we have the warmest of the weather before us.

The condition of basket plants about the middle of August is often anything but satisfactory, and owing to their being subject to dryness more so than pot plants, failures ensue in mid-season. To guard against a contingency like this one should be prepared with renewals, and scarcely anything can be better than young Ivy-leaved Pelargoniums. These will strike quickly enough now, and should be potted on and kept in the house for a time.

TOWNSMAN.

JUSTICIAS AND THEIR CULTURE.

This genus contains a large number of species of easily-managed, quick-growing plants that soon arrive at a flowering state. Most of them are evergreen free-flowering stove shrubs. They strike readily from cuttings in spring, kept

kinds are those that bloom in the autumn. After flowering, those that are to be kept for another year should have their shoots shortened back, and be kept in a temperature through the winter of about 60 degs. by night. In spring shake a portion of the old soil away, and give pots 3 inches or 4 inches larger, striking cuttings of those kinds that it is preferred to bloom in a smaller state, treating the old plants as advised in the summer previous. When the pots are full of roots manure-water is of great assistance. Aphides and red-spider affect these plants; syringe freely with clean water to remove the latter, and fumigate with Tobacco for the aphides. The most desirable kinds are—

J. CARNEA (here figured), a strong-growing, free-flowering species, that bears large heads of flesh-coloured flowers; an autumn bloomer.

J. COCCINEA is a winter or early spring-flowering kind, with scarlet flowers.

Justicia carnea. From a photograph by Geo. E. Low, 2, Glensageary Hill, Dublin.

moist, close, and shaded, and in a moderately brisk heat. When rooted, move them singly to 3-inch pots, giving them good turfy loam, with some leaf-mould, rotten manure, and sand, in which mixture they thrive very freely. Keep them rather close until they begin to grow, when pinch out the tops and give more air, still keeping them in a stove temperature, with a tolerably moist atmosphere, and shade when the weather is bright. When necessary, they will require moving to 6-inch or 8-inch pots, according to the more or less natural strength of the kinds grown. Use the same sort of soil, but let it be now in a more lumpy condition. Again pinch out the points of the shoots, syringe daily, and water freely, as the pot gets full of roots; stand them with their heads well up to the glass, and give air and shade. As the summer draws to a close, dispense with the shade as soon as the plants will bear it, give more air, and put a few sticks to them for support. The most useful

J. LILACINA, a pretty species, flowers at various times of the year.

J. SPLENDENS is a desirable free-flowering kind that may be had in bloom at different seasons, according to the warmth it is subjected to.

GREENHOUSE CLIMBERS.

CLIMBERS on the roof are undoubtedly amongst the attractions of many greenhouses, but unless they are kept under proper control they become more of a nuisance than otherwise, and positively harmful to plants growing therein. For this reason I am an advocate for cultivating climbing plants in pots or tubs, so that at certain times of the year one may remove them to the open air, to the advantage of the climbers themselves and the other occupants of the house. I do not always agree with creepers being grown on a roof to act as a shade for other plants, especially in houses

where mixed collections are grown, because there are certain periods when, dull weather supervening, one needs all the light one can get. Much better is it to have few creepers on a roof and employ blinds on the outside when required, which may be taken down as circumstances demand, than for the house to be in a state of semi-gloom for several months in the year. To avoid this, then, it is desirable to go over creepers now, cutting away all useless shoots, retaining only those that are actually of service. One knows very well what an abnormal amount of growth proceeds from such things as Passifloras, Lapagerias, Cobæas, Clematites, Swinsonias, Plumbagos, etc., and if a couple of seasons' growth accumulates how they darken the house. One sometimes profits by other people's experience in matters of this kind, and I recollect seeing a group of Coleuses that were fast becoming thin, losing colour, and having a drawn and sickly appearance through a roof over-hardened with foliage, but after cutting away all unnecessary branches, the light and sunshine, which had been prevented entering, soon wrought the desired change. What is applicable in the case of Coleuses is also true in the case of all kinds of greenhouse flowering plants. Light must do its part, or otherwise failures ensue. My contention, therefore, that climbing plants should be grown in pots, and so have a change by being placed out-of-doors, will be patent to anyone having to deal with greenhouse plants. I have on many occasions seen Roses planted in borders, and having been in the same house for a season or two, lose their vitality, mainly in consequence of the trying ordeal of being under a glass roof and exposed to overmuch sun, but grown in pots and placed out-of-doors after blooming they have a much better chance of recuperating and becoming stronger.

WOODRASTWICK.

AZALEAS.

Plants that were in flower by last December and January, and duly attended to in a growing temperature, should by the middle of July be fit to place out-of-doors to finish and harden up their growth and form flower-buds at almost every tip, if well cared for in the matter of watering and daily syringing when fine weather comes. The plants should be examined before turning out, and should thrip be found on the undersides of the leaves fumigate at night and next morning, if convenient. If this cannot be carried out, lay the plants on their sides and well syringe with fairly hot water that has a wineglassful and a half of petroleum put in, well mixing together first by working the syringe back into the vessel with as much force as possible. This will prevent the oil from floating on top of the water—in fact, it is much the wisest for one man to keep the mixture well on the move with the syringe whilst another puts it on the plants. Lay each plant on its side, spreading a couple of mats for the purpose, wetting every bit of foliage by moving around the plant. In eight or ten minutes after this application give another good washing with water standing at 110 degs. or even 120 degs. This will remove all dirt and any trace of petroleum. A partly shaded position during summer is best for Azaleas, under a north wall where just the rising sun reaches them and again when setting, standing them on slates or an ash bottom. Should any require repotting let it be seen to at once. Giving small shifts is the motto, using good peat with just a little fibrous loam, and enough coarse silver-sand to make it porous. Let the pots be cleaned and well-drained so that the water passes away freely or bad results soon follow. Any plants that are not in good health should be reduced at the ball and given a smaller pot. These would be better kept under glass for another month or so in case heavy rains ensue, which would be ruinous to the roots, not having laid hold of the new material. Early in September remove the plants to a more sunny position where the sun will thoroughly ripen up the growth. In a favourable autumn, with not too heavy a rainfall, the plants may remain out-of-doors until well into October, a few degrees of frost doing them no harm. When they are housed it may be well to agitate the soil, then as before, cleaning over the surface of the pots

and washing the outside of them so that all may be clean and healthy. Azaleas while making their growth enjoy a little artificial manure scattered over the surface and watered in, say once a week, while a little clear soot-water tends to keep the foliage dark.

J. M. B.

SMALL-FLOWERED ARUM LILIES.

INTRODUCED into this country in 1731, and so universally grown for many years, the Arum Lily showed little, if any, departure from the normal form till about a dozen years ago, when that delightful miniature kind, Little Gem, made its appearance. It was first shown at a meeting of the Royal Horticultural Society in the autumn of 1890, and attracted a deal of attention, an award of merit being bestowed upon it. This variety, the lower-stem of which reaches a height of about a foot, with a spathe in proportion, may be flowered successfully in pots only 4 inches in diameter, and in this small state is useful for various decorative purposes, but where the size of the pot is of no particular moment one 5 inches in diameter is the most useful. The variety Little Gem is

Arum Perle von Stuttgart.

extremely prolific in suckers, and that is the reason why many fail to flower it in a satisfactory manner, for if the suckers are allowed to develop, the result will be pots full of leaves, but few, if any, flowers. On this account the main flowering crowns must be kept free from suckers. Soon after the advent of Little Gem the variety compactum made its appearance, and gained a similar award at the Royal Horticultural Society just twelve months later than the first named. This reaches a height of 18 inches to 2 feet, and bears good-sized spathe, thus belonging to what might be termed the medium-sized class. It still remains a popular variety. Another in the same way is Perle de Stuttgart, here illustrated, which is a comparatively new kind, remarkable for its dwarf, compact habit and large flowers. In the

CULTURE of Arum Lilies in general, whether planted out during the summer or confined altogether in pots, a most important consideration is to remember the conditions under which they grow in a state of nature, and throughout the period they are in active growth keep them liberally supplied with water, while manure in some shape or other is very essential. In the West of England and in some parts of Ireland the Arum Lily may be successfully grown out-

of-doors as an aquatic, and when in a flourishing state it forms in this way a delightful feature. T.

NOTES AND REPLIES.

Bad leaf-mould.—I would warn users of this material who collect their own leaves for the purpose to see that they are properly decayed before using and that no mud or grit is thrown on the heap, or that no dirty water is thrown on to assist, as some think, the more rapid decay of the material. I had the misfortune to have a lot as above described, and after sowing seeds and pricking off plants in soil in which the mould was mixed, I found the seeds failed to germinate, and the plants made no headway. It is well to take a lesson from nature that the leaves which fall in and around a wood make the best of leaf-mould, and it requires neither dirty water nor any other concoction to assist in their decay.—D. McL., B. of W., N. B.

A good variegated greenhouse plant.—Of late years many of our best greenhouse plants do not appear to be much grown. This may arise from the fact that not a few of them are of much value to cut from. Nevertheless, there are many useful kinds, and amongst them must be mentioned *Coprosma Bauriana variegata*, which never loses its bright colour at any season. It is ornamental either in a large or small shape. Small plants in 4-inch or 5-inch pots are useful for house furnishing. Needing many plants for the embellishment of the rooms which are high and dark, I have to use material that is bright in colour, and I find this plant one of the best. Another recommendation, too, is that being grown cold it does not suffer like many things. My plants are always grown in a cool greenhouse, with abundance of air at all times, and are stood outside in summer. A sandy loam suits it well, potting it very firmly. From the habit being slightly straggling it needs the points of the shoots taken out sometimes, and in this way nice compact plants can be obtained. It strikes readily from cuttings put into sandy soil, keeping them close for a time.

Saxifraga pyramidalis in pots.—This is a most beautiful plant when in flower, which is usually in May and June. It requires good treatment to get the best results, and is best grown in pots under glass, though the plant has proved itself hardy in Devon and Cornwall, but the spikes are not to be compared with those that are given glass accommodation. No artificial heat is necessary; plunging in a bed of coal-ashes in a cold-frame will carry the plant through the winter. Free ventilation, whenever the weather admits of its being done, and little or no water at the roots, and keeping the plants within 6 inches of the glass and free from drip, are all that it requires while in this position. As soon as the plant passes out of flower remove the side growths with a knife with root attached, and either place in thumb pots or dibble into pans and pot up in early spring. Loam with a dash of leaf-soil, with a good percentage of broken bricks, I find a suitable compost to grow them in. These offshoots require two years' growth before they show flower, so a fresh stock must be put in each year. After flowering the plants die away, some without throwing off any side shoots at all. Young plants put in now into small pots will not require repotting for a year, when transfer into 5-inch pots, potting firmly and standing out-of-doors in the full sun, watering with care until growth is active, when a plentiful supply will do no harm. No stimulant will be necessary until the flower-spike shows, then it may be given weak. Keep the plant in the cold-frame or pit until the flowers begin to expand, when remove to the greenhouse or conservatory, and keep dry overhead or the flowers soon get spotted. A neat stake should be put to the spike, which reaches to a height of 2 feet, to keep it erect.—J. M. B.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of *THE HOUSE AND GREENHOUSE PLANTS*, or "THE ENGLISH FLOWER GARDEN" to the sender of the most useful or interesting letter on short articles published in the current week's issue, which will be marked thus *.

OUTDOOR PLANTS

SCHIZOPETALON WALKERI.

This curious half-hardy annual comes from Chili. It grows about 1 foot high, and bears on slender stems numerous white, almond-scented, fringed blossoms, which are well shown in our illustration. It will be found very useful for cutting for the house. If sown in April or May in a light, warm soil in the open border, it flowers through July and August. It may also be raised in pots and transplanted, but when thus treated great care must be taken that the ball of soil does not get broken, as it is impatient of disturbance.

NOTES FROM IRELAND.

COLUMBINES are beautiful in June, when the collection is rather large and varied, and this weather is in their favour, for in a hot, dry season they do not last long in bloom. Tall, double, large-flowered varieties are really showy, the colours being all shades of purple to almost black, blue, red, and pale shades to white. There are also purple and white or

double or single, scarlet and yellow, and other colours. *A. chrysantha*, *A. cornuta*, and *A. vulgaris* give good hybrids. One still living, having been planted in the shelter of a bush, had blossoms 3 inches or 4 inches in diameter, the petals of a creamy-gold outside, large sepals tinged lilac-purple, and it very often comes true. A scarlet-red double one may be a hybrid of *A. californica* and *A. vulgaris*. Two groups of *A. Jatschani* are good, the blossoms being almost invariably double, and either purple, purple and gold at the mouth, or red and yellow or deep pink. Formerly I had excellent hybrids myself from *A. chrysantha* and *A. Skinneri*, the blossoms with long red spurs and goblet centres looking, late in the afternoon, like lamps hanging from the plants. A collection of Columbines is always changing, old plants dying out, but when seed is sown annually, new types of flowers in build, also new colours, present themselves, since, in addition to what you may be doing in the way of hybridising, other agents may be assisting, while there is, besides, the law of variation in these plants, and it only needs the inferior varieties to be kept constantly weeded out and

Dielytra was pretty. The thin, shining, very pods of the white *Honesty*, when the valves of the ripe pods are removed therefrom are perhaps better than those of the common coloured kind. A plant of *Geum* miniature with thirty or forty stems, has been flowering since early in May, and is showy with its orange blossoms. *Polemonium coruleum* alba is now in flower beside *Geum* *miniaturum*. Double scarlet *Geum*, now opened, has been good as scarlet *Geraniums* sometimes. A dwarf, large-flowered *Myosotis* has been pretty as edging, and is still so, the rain but beautified the numerous blossoms. The ordinary *sylvatica* is not to be compared with it, an annual *Saxifrage* with Ivy-shaped leaves growing beside the dark-leaved *Ajuga* pretty, the numerous yellow blossoms of the *Saxifrage* contrasting with the blue ones of the spikes of *Ajuga*. An interest can be taken in seedling *Daisies*, many good varieties resulting in this way when the seed is good and inferior yellow-centred varieties can be pulled up as they appear. The old *Hen-and-Cluck* *Daisy* still gets a place. *Pyrethrums*, double and single, are beautiful; whatever the character of the season these hardy plants do well. Perennial *Cornflowers* are more interesting than that there are varieties of them, of which the cream coloured is one of the best. A seedling European *Globe-flower* is an improvement on the type, the sepals being broader and white, covering the centre. The star-shaped flowers of *Cerastium* in a warm site are pretty, Arabis being over. Both *Arabis* and *Aubrieta* were later this year owing to the weather. *Pulsatilla officinalis* and its white variety are worth growing because of their early flowering. *Wallflower Ruby Gem* is a good variety, coming mostly true from seed.

Roses are not much in flower yet, but the *Paeonies* are, and there are still a grandeur and beauty in these fine, large, hardy flowers whose scent, such as it is, I have always liked. It does not take many flowers for a vase when *Paeonies* are used. *Lily of the Valley* flowers well this year, the season suiting it. *Convolvulus* (*Calystegia sepium*) was established itself here, having spread out from a wall. The stems of the *Convolvulus* were permitted to grow until they acquired a little toughness—they were then pulled up with a portion of the white base generally. This was practised for more than one year; now there is no *Convolvulus* in the place nor along the wall where it spread to the border. Some common *Scilla* drops, single and double, are grown with the *Lily of the Valley*, the spot being warm and early, and the two plants grow harmoniously enough together. *Polyanthuses* bloomed profusely, the month of May still seeing some of the giant yellow and white varieties, these being the showiest, though the red and magenta kinds are nice. There was one fine *Primula* which got named *Lord Beaconsfield*. It is not a true *Primula*, sending up scapes late, and hardly until it has exhausted itself in *Primula* fashion. The species of *Primula* sometimes get unfavourable weather to open. *P. rosea* generally manages to display for a time of bright rosy blossoms; *P. denticulata* got killed occasionally; *P. Sieboldi* is too tender, whilst a crowd of little blossoms are on the trusses of *P. casimeriana*. *Tulips* (the late kinds) were lovely in May, beds of these being gay beside *Spanish Scillas* and other things. Of the species, or wild sorts, *T. acuminata* was early in bloom, lasting long. A scarlet strain ran down the petal of one flower of *T. Bellefleur*, so that these can vary too. *T. Geometrica* is an ornament wherever grown. *Tulips* have a richness and colouring entitling them to a high rank among flowers, and in this require care they are worthy of it. I gave lately in GARDENING a handsome photograph of *Crocus verus* in the Grass. I raised some corms of one, when it was in flower, a spurious kind having got amongst them. This is rather a distinct kind of *C. vernus*, with fine white stigma, which I named *C. French* after the giver of the parent corm, Rev. Edward French. A large blue (or purple) *Crocus* with eight segments, four stamens, and a four-lobed stigma, and, as this is the second year that I come this way, it supports the opinion that it is a seedling. A *Dog's-tooth Violet* had eight segments to the flower and an increased number of other parts, this enhancing its beauty.

Schizopetalon Walkeri. From a photograph by Geo. E. Low, Bulletin.

blue and white varieties, *Aquilegia glandulosa* or *A. Wittmanniana* being responsible for the white open tips to the petals. In the double varieties the petals are recurved or plain, both being nice. Tall single varieties with large, bell-shaped flowers, having long sepals, red, pink, pink and white, and blue, and other shades, are also showy. When this style of flower is associated with dwarfness of habit it comes near to *A. alpina*, true. There are also dwarf-growing double varieties in a number of colours, some being edged at the mouth of the petals with silver. The most perfectly double have the spurs twisted at the base, this being a neat style of flower; but loosely built double blossoms are also nice. The kinds with spurless petals, when moderately double, are pretty, their drooping, spreading blossoms having a fine column of stamens. A dwarf-growing kind, with erect double flowers, now in different colours, is interesting where drooping blossoms are the rule; it is *A. sibirica* pl. Usually the first flower of any plant to open is the best, regarding doubleness as well as the best, but this is not the case always with Columbines, since the first blossoms to open may be single, the succeeding ones double. Hybrid *Skinneri* with *A. vulgaris* are pretty, being

destroyed to keep the collection up to a certain standard of goodness. One Columbine shows the sepals doubled in number—ten—the flower, which is double, being singular even among these quaint plants. The American species are not lasting here, and sometimes capricious, too, in the flowering.

Rockets (*Hesperis*) are in fine flower now, the colours of the blossoms varying from clear white to lilac, or purple almost, or speckled, and, when planted in mixture, are pretty, having also a sweet scent, especially in the afternoon. The double kinds require here strong, rich soil, retentive of moisture, to enable them to send up strong stems. *H. tristis*, which is a remarkable plant, commenced to flower early in May. An insect affected the foliage of the common *Rockets* in May, their points being caught with a web, this excluding the air from the flower-buds, and I thought it worth while opening them and killing the small, smooth, caterpillar which was the cause, and which "G. S. S." knows all about. Some plants of the white variety of *Honesty* grew beside *Dielytra spectabilis*, and were permitted to flower where they sprung up, and the appearance of the large pyramidal plants when in blossom beside the arching racemes of pink flowers of

Leucojum vernum flowered well; its bells are finer than those of the summer Snowflake. Yellow Turk's-cap Lily, the broad-leaved kind, is flowering. The plant of this species, with narrow, linear leaves and a more graceful and different blossom, is still in bud. The distinction between the two is maintained in the fruit, this being longer and broader at the top in the narrow-leaved kind. It is the broader-leaved variety that is oftenest met with. A narrow-leaved purple Turk's Cap is pretty, its blossoms being as distinctly spotted as those of *Calceolarias*, but it is not so hardy as the commoner broad-leaved purple, and transplanting prevents it flowering. *Verbascum pyramichitum* is seeding up its stems, also *Digitalis lutea*. *Bocconia cordata* is a good height in a sheltered position, later to bear its plume-like panicles of sweetish-scented blossoms. *Sanguinaria canadensis* was of lasting quality this year, its glistening white flowers remaining a long time good. It is well that Tufted Pansies and Pansies (seedlings) are so hardy that they can endure a severe winter and give us their blossoms when the year begins to get properly warm. Some seedlings of the Tufted Pansies are elegant, being yellow, primrose, white, blue and white, and other colours. Pansies of the German strain growing out in the open are flowering well. Orchids are pretty on the north side of a rock-

the year, but I have found that by getting the seed in from the middle of July to the middle of August one obtains plants calculated to stand the winter better. Inclosed Poppies last well when cut and are slightly scented. Too many, I fear, who care for them overlook until spring that seed to do any good should be sown in July or August.—TOWNSMAN.

YUCCA FILAMENTOSA.

THE various species of *Yucca* are particularly valuable in our gardens, for there is no season of the year when they are not decorative. Naturally, the period of their highest effectiveness is that when they bear their tall, ivory-white flower-heads, but even when they are flowerless their cool, grey-green foliage is always pleasing to the eye, both on account of its colouring and its noble form. *Yucca filamentosa*, popularly known as Adam's Needle, the species figured in the accompanying illustration, is the freest bloomer of the family, as, when once established, it almost invariably flowers annually. Being of comparatively dwarf habit compared with others of the genus, and taking up but little room, it is the one best-suited for the small garden. Herbaceous borders, even the narrowest, are greatly improved by a few of these plants, which tend to break the line. In wide borders, groups of

standing the hardest frosts with impunity. Many of the other species, coming from more southern districts in the American continent, are tender or at best only half-hardy.

S. W. F.

RABBIT-PROOF PLANTS TO FLOWER IN AUGUST.

(REPLY TO "CASTLEMANS.")

RABBITS have not touched the following in S. Devon: All vars. of Perennial Astors, P. Sunflowers, *Helianthus*, Golden Rods, and *Railbeckias*. These are wild plants in the woods in the U.S.A., all hardy, but the Brass must be cleared from their crowns, and, indeed, from all this kind of plant. They are glorious in their union of gold and lavender. Whether they will be too late for August in the north I do not know. All the St. John's Worts are safe and beautiful. There are not many plants suitable for wild gardening that would be safe; but for spring and early summer there should be added to the list Snowflakes, Solomon's Seal, the Gloxinia-flowered Foxgloves, single Paeonies, "Flag" Iris (*Iris germanica*), single Rocket, and, by the burn, double and single King Caps. Would Oriental Poppies do? They are rabbit-proof. I do not think "Brere Rabbit" would touch wild Poppies or Corn Marigolds.

Adam's Needle (*Yucca filamentosa*) in Col. Baskerville's garden at Crowsley Park. From a photograph by Mr. Thomas Taylor.

garden. The first Oriental Poppy flower is open. Spores of *Lycopodium selago* were scattered on the surface of a pot containing white Heath, and now one or two young plants are to be seen; a prothallus was not noticed. A few plants of *Lycopodium selago* look well in a pot—they look so like miniature conifers.

Frost was rather severe on some plants last winter. *Muhlenbeckia complexa* was injured. *Helleborus orientalis* escaped, but a little choiceness of site is beneficial. *Phytolium capensis* bore the ordeal well. The Barbary Ragwort (*Othonna cheirifolia*) was potted and kept safe; this plant has rather nice and distinct, erect, smooth, glaucous, obtuse foliage. *Hypericum Moserianum* was killed in the top parts of the plants, but it springs up from the thicker wood lower down. Cuttings of it struck in the summer or autumn, kept safe during winter, and planted out in the spring in rich soil when frost is gone, give fine large flowers in the late summer and autumn. In the newly opened blossoms of this hybrid St. John's Wort the red-anthered stamens look pretty standing in their saucers of gold.

R. L. K.

Iceland Poppies.—Some Iceland Poppies which are now in bloom in my garden remind me that the plants were raised from seed sown last July and wintered on a dry border under a wall. Some growers, I believe, sow late in

four or five give the most pleasing effect, while in narrow ones a single plant will prove sufficient for one spot. The charming picture presented by informal grouping of half-a-dozen plants or so in the Brass in front of shrubs and evergreens is well portrayed on this page. The great *Yucca gloriosa* is an especially striking object on a lawn where it has been established for many years, as in this case it spreads over a large space of ground, forming numerous heads of various heights, and often bearing many towering flower-spikes simultaneously, the tallest of which sometimes exceeds 10 feet in height. This species often produces its bloom-spire late in the season, and in the south-west it is no uncommon sight during a mild winter to see one in full blossom in December. There is a variegated form of *Y. gloriosa*, which is but rarely seen. It is a strikingly handsome plant, and flowers as freely as the type. *Y. pendula* has drooping foliage which imparts to it a graceful and distinct appearance, and renders it perhaps the most attractive of the family. It is held to be a variety of *Y. gloriosa*, but rarely attains the same dimensions, and bears its flowers more loosely disposed upon the spike. *Y. flaccida* is a form of *Y. filamentosa*, from which it differs in its leafage being less erect. There are also many other species and varieties, but those mentioned, which are natives of North America, are the best for gardens as they are absolutely hardy with-

or, indeed, "pot" Marigolds; at any rate, they do not do so here. They also let alone the wild Columbine (*Aquilegia vulgaris*), but graze down the hybrids. *Lilium tigrinum* and *L. speciosum* would thrive if planted in groups and surrounded by 1-inch mesh wire netting, 3 feet high, but also 1 foot in the ground; the Brass would almost hit the wire. The first would about suit for time; the other would, perhaps, be late. All these plants are quite hardy and cheap, and increase quickly. It would be well to try Chicory and Viper's Bugloss (the latter a biennial). Their blue is perfect. But to make real pictures, fine-foliaged plants should be used. A group of *Bocconia cordata*, 8 feet high, arching its heads of soft brown flower-buds over a huge clump of scarlet Poppies, every passing breeze turning its lovely grey-green leaves to show their silver lining, is a sight worth seeing. They are beautiful, too, by water. The Giant Rhabarbs (*Rheums*), Fennels, and *Acanthus* are quite hardy, and quite as beautiful as tropical plants. These, also, are more "in keeping" if planted by water. All die down in winter, out of harm's way. Little or anything would touch them in the summer with better food-plants about.

A. B.

Dwarfish.

—Concerning your answer to "A. H. F. M.," in *GARDENING ILLUSTRATED*, p. 223, as rabbit-proof plants, the following may be of service

to your correspondent. A short time since I had occasion to consult several authorities on the subject of rabbit-proof plants, and found, singularly enough, that there were considerable differences of opinion—that is to say, plants that escape in one district would be eaten in another, and *vice versa*. However, the matter was thoroughly discussed, and the following list of plants drawn up, which might be safely planted where rabbits abound (short of insuring an actual warren) without much risk of their being troubled by these animals. Shrubs: Azaleas, Rhododendrons, Spurge Laurel, Juniperus Sabina, Potentilla fruticosa, Furze or Gorse, Forsythia suspensa, Forsythia viridissima, Jasminum nudiflorum, Lilacs. Tree: Peonies, Symphoricarpos racemosus, Ruscus aculeatus, Ruscus racemosus, Leyceum barbatum, Eonymus japonicus, Ligustrum vulgare (Privet), Hypericum androsaemum, Yucca gloriosa, Hydrangea Hortensia, Rhus Cotinus, Box, and Helleborus viridiflorus. Herbaceous plants: Tritonum, Iris, Winter Aconite, Narcissus, Solomon's Seal, Lily of the Valley, Aquilegia, Periwinkle, Scillas, Delphiniums, Primrose, Anemones of sorts, Violets, Poppies, Foxgloves, Pansies, Stachys latata, and Muscari. T.

NOTES AND REPLIES.

Crinums.—Beautiful subjects are the Crinums, but too often absent from gardens where their culture could easily be undertaken. What suits them best is a warm, sheltered border where the soil is rich, and where they will not have to be disturbed. Their blossoms, which are borne in umbels, are nice for cutting, and come in useful in the autumn. *C. capense* and *C. Moorei album*, pink and white respectively, are the best known. It is advisable to give them a slight covering of leaves, etc., during the winter.—TOWNSMAN.

Madonna Lily diseased.—I enclose a stem of Madonna Lily. I have a border with twenty-four large clumps, about 2 yards apart all down it of *M. lilies*. Just lately five clumps together have been spoilt as enclosed. My gardener says it is the hot sun, which has been out at 4.30 a.m. on top of the frost, which we have been having last week, but I would be glad if you could tell me if it is the dreaded Lily disease? These lilies have been in five years and do so well always in stiff clay soil. The rest of the clumps do not seem to have been touched. What remedies do you recommend?—EDELWEISS.

[Unfortunately, the stem which you send has been attacked by the disease so liable to attack this Lily. Lifting the bulbs and shaking them up in a bag of sulphur has in some cases proved a remedy, whilst in others lifting and baking in the sun have also been efficacious.]

Columbines.—A hunk of these lovely old-fashioned flowers, grown in a country garden and which was put into my hand the other day, showed very clearly what a deal one may do in having showy borders where Columbines are grown. They offer a range of quaintly marked flowers, which last for a considerable time, are not the least interesting when arranged in vases for table decoration, and are, moreover, so easy to rear and keep during the winter that anyone with a garden need not despair of growing them. No better time can be chosen than the present for sowing seed in the border. Some of the selected hybrids of to-day are charming.—LEADHURST.

Silenes.—For planting out in autumn for blooming in the border next spring, now is the time to plant *Silenes*, or where pink blossoms are wanted in the greenhouse early, a few plants lifted, potted up in autumn, and placed in ashes in cold-frames, being subsequently brought on gradually in heat, will be found useful. Once *Silenes* were thought much of where a spring display of flowers is sought, but for some unexplained reason they have waned in popularity. They are, however, worth the little trouble needed, and this consists in sowing the seed in the open in July in a rather shady border where moisture obtains, as sometimes on dry soils the seed fails to germinate. *Silene pendula* is probably the best known, but the double white and rose forms, dwarf and compact, are also useful.—TOWNSMAN.

Early garden exhibitions.—There can be no doubt that the shows fixed for late July and in August will be the most useful and best furnished this year. I refer, of course, to the ordinary rural cottages shows, the earliest of

which I have to attend is on July 10th. Always an early date, it bids fair to be fully a couple of weeks too early this season, as everything is so late. Certainly we may have some warm weather yet, but we should have had under ordinary conditions needed warmth for the past month, yet with one or two fine days the time has been both singularly cold and gloomy. Practically nothing can be done to help accelerate the growth of ordinary crops, such as Peas, Potatoes, Onions, Beans, Carrots and various other vegetables, whilst ordinary hardy fruits will all be late. Cabbages and Lettuces may be very good. Tomatoes, Cucumbers, and Marrows must all be late. Even many ordinary early summer flowers will be rather late, although the unwanted moisture has done wonders to strengthen hilly herbaceous plants, and whenever they bloom they should in the course be very luxuriant.—A. D.

Fairy rings on lawn. I am writing to you hoping that you can suggest a remedy for what is a great disfigurement to the lawn. Three or four fungus patches have appeared, which each year extend in circumference, leaving the centre free. My efforts to remove them have been in vain—they are flourishing as strongly as ever.—A. STREBBER.

[What you refer to is known as "Fairy-rings." They increase in size annually, for the spawn of the fungus prefers fresh soil every year, pushing outward into that in which it has not previously grown and dying away where it has been before. The dead spawn forms a very nutritious manure for the Grass, consequently the latter grows more luxuriantly on that part of the lawn, and forms the "fairy" rings, the fungus itself growing on the outer edges of the rings. Sweep off the Tondstools as soon as they appear and before they have had time to disperse their spores. To get rid of these rings the surest way would be to take up the turf outside the ring for about a foot in width from the edge of the dark Grass, and replace with fresh turf. Watering with 1 oz. of sulphide of potassium dissolved in 4 oz. of water might be useful. A good dressing of Kainit is said to kill the fungus.]

Bedding plants.—This is a dreadful year so far for those who are abandoned entirely to bedding plants. I went to a large place the other day in the country—one of the most famous in the county—and there was not a flower on wall, garden, or Grass to be seen in the place. The bedding plants had just been put out in this cold June, and very bad they looked in the hard, conventional flower garden in front of the house. But as the season is, the really hardy plants have endured it very well, some better than ever, and I am more and more convinced that the true way of a beautiful flower garden in our country is to try hardy plants alone. I was even afraid to put out the *Heliotrope*, which, at the best, can only give us a short season before the frosts come again. When on this subject I may speak of the great deterioration I notice in our gardeners raised in this hot-house way. It is often very difficult now to get a man who takes any pride in outdoor work or who can dig a bit of ground in a right and level way, or prune a tree in the old and careful way that was common to good Scotch and English gardeners and is still the rule in France. It seems to me we shall have to begin to educate our gardeners again on something better than the pot and kettle business of the hot-house.—S. J.

Spring flowering perennials.—I wish to establish a border composed of spring-flowering perennials, and would be grateful to know whether any members of the Ranunculaceae family, flowering in April or May, are averse to a somewhat heavy, clay soil? Also, whether this same soil suits any of the low-growing Sedums and Saxifragas—those that are used for carpeting? I should also be very glad to know the Latin name of Harrison's Musk, lately described in *GARDENING* as a useful carpeting plant?—SWISS SUBSCRIBER.

[There are many beautiful spring-flowering plants that are never so well suited as when growing in good, holding clay soil, and there is no reason why such a border with the right class of plants may not prove a success. In this connection you inquire whether any members of the Ranunculaceae family would succeed, preferably those flowering in April or May. Of these we may first mention *Ranunculus speciosus* and *R. aconitifolius* fl.-pl., the latter with pure white and double flowers in great profusion. There is also a single white

of this. Another highly ornamental species is *R. amplexicaulis*, and with every hope of success you may try some of the florist's *Ranunculus* (R. asiaticus) in variety. *Paeonia officinalis* forms and *P. tenuifolia* and its double variety would be very beautiful. To these many fine single kinds may be added. Then, again, in *Hepatica* or *Anemone* you have a wide range, particularly in the latter the forms of *A. coronaria*, with *A. fulgens*, *A. sylvestris*, *A. s. fl.-pl.*, all of which are fine spring flowers. Then you have the *Globe-flowers* (*Trollius*) at your command, and these are all May flowering. Nor will you err if you add a few things from such groups as *Arabis*, the new double white particularly, and many *Candytufts*, such as *Iberis corioliola*, *I. superba*, *I. Little Gem*, *I. sempervirens*, *I. Garretiana*, etc., all beautiful, free-flowering, and dwarf. The alpine *Phloxes* are also beautiful. In *Saxifraga* you may grow such as *S. Wallacei*, *S. granulata* fl.-pl., *S. umbrosa*, *S. Cotyledon* var. *pyramidalis*, *S. peltata*, and the whole of their near allies, the *Megaseas*, some good ones of which are *M. cordifolia* purpurea, *M. crassifolia*, etc. There are also many fine hybrid forms too little known at present. To the above may be added *Corydalis nobilis*, *Senecio Dronicum*, the lovely *Arnebia echioides*, many charming kinds of *Thrift*, *Dianthus barbatus*, *magnificus*, etc. If you wish for bulbous things, you could plant *Narcissus poeticus ornatus* and *N. p. fl.-pl.*, planting the latter quite 6 inches deep at the least and better at 8 inches. Also plant it thinly, that it may stand for years, as disturbance to this kind is injurious. *Primula caschmeriana*, *P. rosea*, and *P. Sieboldi* in variety will also appreciate a heavy soil, and the last-named full moisture at all seasons into the bargain. Of *Sedums* and *Saxifragas* for carpeting you may employ of the former *S. hispanicum* and *S. h. glaucum*, also *S. acre elegans* and *S. albidum*. Of the *Saxifragas*, any of the more elegant Mossy kinds—*e.g.*, *S. hypnoides* and *S. h. elegantissima*, *S. Sternbergi*, *S. Stansfieldi*, *S. carpitosa*, etc. All are beautiful, free, and easily established by pricking the single rosettes over a given surface in spring or autumn. "Harrison's Musk" is *Mimulus Harrisoni*, but the former popular name is always ample. It is a pretty and freely-flowered plant.]

New Dahlias.—It is necessary, if one wishes to have the best in a rapidly improved flower like the *Cactus Dahlia*, to purchase a few new ones each year. Out of the great number exhibited the difficulty is sometimes in the choosing. The price of new Dahlias is 7s. 6d. each; it is, therefore, an expensive hobby. It often happens, too, that a new variety is seen that one feels he must have—like the white *Lord Roberts* of last year and the *Mrs. J. J. Crowe* of the year before. Whilst I do not think there are any new sorts equal in merit to the above-named, there are, nevertheless, several very striking kinds forthcoming. *Clara G. Stredwick* is a variety which will supersede *Magnificent*. It is of a more elegant shape; the florets being very narrow; colour salmon-shaded yellow. *Ringdove* is a chaste and beautiful sort of a white-fawn shade, most distinct and pleasing. *Gabriel* has blooms the ground colour of which is crimson, the upper half of the florets being pure white. This is the choicest of the two coloured kinds that have yet appeared. It is a nicely formed flower. *Mrs. A. F. Perkins*, yellow shading to white at the tips, is a pretty thing in every way. Another nice yellow is *Mrs. Edward Mawley*. It is deeper in colour than the last named, and its long, narrow florets incurve to the centre. This is distinct. *Anat Chloe* is a very dark blossomed kind, lighter in arrangement than *Uncle Tom*.—H. S.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1. Mr. W. R. Mills, Avlington Farm, Fairford, Gloucester, for Garden in front of house; 2. Mrs. Stuart Rickman, Arborfield Grange, Berks, for Empress Daffodil forced.

FRUIT.

THE FIG IN SUSSEX.

We suppose that Sussex is not quite the most sunny county in England, but for some reason or other it suits the Fig the best, as far as we know. Although the Fig has a wide range in Southern and Eastern England in which it fruits, we think the handsomest wall of Figs we have seen is at Glynde, in Sussex, of which we are happy to show a view.

Fig culture, even in counties not so favourably situated, is quite easy so long as we grow it on warm walls. We think the tree deserves a little more attention than is usually given to it, and also that there should be a change of variety. The Fig commonly grown in England is a great big stodgy fruit, very good when you get it; but the Figs of Spain and Northern France should also be tried, as they would give

have no sun, and with a cold, biting wind always blowing would only make matters worse, as although the fly might be washed off or destroyed, the wet would be productive of much harm. Vegetation will stand a great amount of cold so long as the atmosphere surrounding it is dry, and, tender as the young leaves of Peaches and Nectarines are, they form no exception to the rule; therefore during such times as these every effort should be used to screen them from damp as much as possible, as under such adverse circumstances nothing is so fatal to the flowers. Rather than syringe or wet the trees thus early under the present unsettled state of the weather, it will be advisable to go carefully over them with Tobacco powder, which, puffed among the young shoots by means of a cheap, handy distributor, now made and sold for the purpose, will soon destroy the fly. A small tin of Tobacco powder used judiciously will go a long way if applied during a still day, as otherwise

insecticides made for the destruction of red-spider and green-fly, but if not very carefully applied and properly diluted they are dangerous, and often do considerable harm to the fruit. For use in a liquid form there is nothing so safe and effectual as Tobacco juice, obtained by steeping the Tobacco in boiling water, and adding thereto an ounce of soft soap to every gallon, and if some Quassia chips be soaked or boiled with it the mixture will be all the more effectual. A pound of Tobacco added to the ingredients just named is sufficient to make 10 gallons or 12 gallons of a strength that will kill green-fly almost directly it touches it. A decoction made as above stated is always handy to keep in a large bottle for the purpose of dipping fruit-tree shoots into, and also those of Roses, for it frequently happens that if taken in time the spread of these insects may be stopped at once, and much after-labour and annoyance saved.

Peach and Nectarine-trees growing on walls

Wall of Fig-trees at Glynde, Sussex. From a photograph by G. A. Champion.

us a difference in flavour, size, and quality. In particular, one called "Dauphine" and another called Blau d'Argenteuil, are excellent. Occasionally we have noticed a Fig doing pretty well as a standard in the same county, and often in the Thames Valley in the little parks we see Figs on the trees now. It is such a very distinct tree as a standard that it is almost worth growing for its foliage.

INSECTS ON FRUIT-TREES.

THE unseasonably cold weather which we have experienced for a long time past has not only been injurious to the blossoms of all fruit-trees, but, owing to their slow rate of growth, has rendered them a prey to insect pests, more especially to the green-fly, with which Peaches and Nectarines are now in most places badly infested. In fine, warm seasons these are easily dealt with, as then one need have no hesitation in using the garden engine and freely wetting the foliage, but to do so while we

there is much waste, owing to its being very light, and therefore easily blown away. As this Tobacco powder lodges in every curled leaf and on the tips of the tender growth, it soon makes these positions very uncomfortable for insects. In order to cleanse the trees, when the weather gets more favourable wash off any stragglers that may have escaped; there is nothing better than a well-directed stream from the garden engine; but the jet should be broken, and not allowed to play against it with full force, unless at a long distance off, so as to diminish its power. In order to give the trees and wall time for drying, this operation should be done early in the morning on a warm, sunny day, but by-and-by the evening is the proper time for such work, as then it has a very refreshing effect and prevents the spread of red-spider, a pest to which Peaches and Nectarines are particularly subject. Fortunately, however, they cannot endure cold water, which not only keeps them moving, but breaks up their webs.

Some use one or other of the many kinds of

derive much benefit from being syringed with soap-suds every week or so, followed daily with clean water. Whenever soap-suds is used the foliage soon assumes a changed look for the better, and remains in a healthy condition. Apricots, though not subject to green-fly or red-spider, are very liable to the attacks of a maggot that curls up the leaves and eats its way out. These should be searched for and destroyed, or they soon do irreparable mischief. The Gooseberry caterpillar is one of the most annoying and destructive of insects, as it is so voracious that it clears all before it—that is, so far as leaves are concerned. Many resort to picking it off by hand, but the quickest way to exterminate it is either to dust the bushes with Hellebore powder, or syringe them with a decoction made from steeping leaves of the common Foxglove in water. In order to deal with the aphid on Currants the best way is to snip off the tops of the young shoots, as it is from the tender leaves there situated that they attack.

PEAR-TREES UNHEALTHY.

I SEND you some leaves and fruit taken from Pear-trees in my garden. You will see they have been attacked by a larva or fungus. All the Pear-trees in my garden have been similarly attacked. Not one of the other fruit-trees has suffered. Can you inform me what the disease is, and suggest a remedy?—J. C. A.

[This is a bad attack of the Pear-leaf rust (*Roestelia cancellata*), and though not often heeded, is much more prevalent and injurious to Pear-trees than is generally supposed. Very few fruit gardens are really free of it, but instances of the whole of the trees being overrun by the rust are, happily, rare. The first symptoms of it are small raised yellow spots thickly dotted all over the leaves, giving them the appearance of being blistered, these spots eventually changing to a rusty brown colour. Experts state that this is the work of a fungus, which, owing to its penetrating and spreading under the epidermis, or thin membranous covering of the leaf, is very difficult to combat. The best that can be done is to pick off the affected leaves at once, or before the spots change to a brown colour, with a view to checking a more widespread attack. If the trees are very badly infested by the fungus, wholesale clearance of the leaves would scarcely be wise, especially if there is fruit to be considered. All that can be done is to allow the disease to take its course, but in order that activity at the roots may be sustained, no summer pruning should be resorted to. If the trees are not starved at the roots, many of the shoots may, so to speak, grow out of the disease, and any way the fruit will be more likely to swell to a serviceable size and the trees be less weakened than would be the case if either pinching back or early summer pruning were practised. All leaves that turn black and are on the point of dropping should be collected and burnt. Next winter, after the trees have been pruned, they may well be cleared of all rubbish, including any about the border, and then receive one or two thorough syringings with the caustic alkali wash so frequently referred to in these pages. This would probably destroy most of the disease germs resting upon or in the neighbourhood of the trees, and next season's attack could then be met by hand-picking the affected leaves. Diseases and insect pests are far more rife than they were last year, owing, probably, to the abnormally early and very tender growth of the trees being greatly checked by the cold nights and easterly winds.]

RASPBERRIES INJURED BY FROST.

THESE are usually looked upon as hardy—so hardy, in fact, that frost has no ill effect upon them. Such, however, is not the case, for this spring a great thinness of growth is apparent in my wire-trained canes, which necessarily means a light crop of a useful summer fruit. Absence of maturity can scarcely be an attribute of such a season as that of 1901, though with vigorous plants there is such a wealth of foliage that probably the sun's influence did not reach the canes. This explanation would seem all the more feasible because in younger plantations, where there is not the same density of foliage, there is no sign of injury to the canes and buds from frost. The failing is not due to neglect of summer pruning, for directly the crop is exhausted the older fruiting wood is cut out so as to give the young growths the advantage of all air and sun possible, with a view to their maturity. In some gardens and soils Raspberries remain productive over a much longer period than in others. I find it necessary to replant a portion of the bed each autumn. This is carried out piecemeal so that the summer crop shall not suffer in extent. I find that those canes planted in October last and cut down to about 12 inches from the soil give a few fruits of very fine quality and size from the growth issuing from these shortened stools. Those which are a season older give a fine crop, too, of heavy berries, and this graduation proceeds through the bed proportionate to their age and date of planting. All the older portion of the bed at the present time shows this loss of vitality from frost, and those of your readers who may have similar experience would do well to consider the advisability of the transfer of a portion of the bed to fresh soil. Crowding must be guarded against, par-

ticularly if replanting cannot be conveniently practised. The green suckers now springing up from the roots can be carefully lifted and transplanted to a piece of vacant ground, either temporarily or permanently. They should be so lifted that new fibrous roots are attached in sufficient quantity. It can scarcely be hoped to establish rootless suckers in mid-summer. In carrying out this work it should be remembered that the suckers farthest from the base of the fruiting-cane are those most convenient and easy to replant, and there being always a superfluity of these suckers to be dealt with in established beds, no loss is sustained in their removal, and by planting them in another quarter in summer they are gaining time compared with others moved in autumn. W. S.

EARLY RIVERS' PEACH.

IN some of the early Peaches there is the disappointing trait commonly known as stone-splitting, and in the above kind this seems peculiarly pronounced. There are instances in which stone-splitting occurs from quite local circumstances, in others the habit seems chronic, and there does not seem any easily explained reason for it, or a ready cure. I have recently had brought to my notice a tree of the Early Rivers' Peach which has for the past nine years given this trouble, and while inquiries have elicited varied remedies and opinions, the trait continues as bad now as at an earlier period. Almost every fruit develops with an open stone, which makes it absolutely unsaleable, and of but little value for home use. Some of the fruits on being opened are found half-destroyed from the core outward to the skin. Such fruits cannot, under any circumstance, have a properly developed flavour. By some the failing is attributed to absence of lime, in others to improper fertilisation of the flowers in spring, but it has been proved that while these conditions have been studiously attended to the failure still continues. When remedial measures such as these afford no relief, the better it not the only course to take is to cut out the tree and replace it by another and more reliable one. There certainly is no need to grow such an unreliable kind when so many others are available. The case referred to has been allowed to go on for such a length of time that the tree now covers a space of over 300 square feet, and bears heavy crops. The sacrifice in destroying such a tree would be, in one sense, a heavy one, but a greater gain would follow if, after writing a short time, good fruit were produced with the same expenditure of labour. In some soils Early Rivers' may do well enough, but it has so often failed that it is scarcely deserving of the effort to prove whether local circumstances meet its requirements, at any rate, not in a position where a permanent tree is desired. W.

AIR-ROOTS ON VINES.

WHAT are known as air-roots on Vines are the root-like growths which push from the wood above ground. They generally appear in the greatest quantity near the spurs, and less frequently upon the clean wood or stem. They usually number from two to a dozen, or even more, sometimes coming in bunches, and sometimes in rows. They resemble earth-roots in some respects, but they do not often divide into rootlets; they begin to grow with the rise of the sap, and continue growing until it descends again. All varieties of Vines are subject to them, and it is often said they do no harm, which may perhaps be correct so long as they are few and small; but there is reason to believe that where they occur to any great extent they at all events do no good. I was lately requested by an amateur to come and see his Vines, as he could not understand why he had no Grapes on them this season. I ascertained that for some years air-roots had been annually increasing and the crops diminishing. This year they hang down over 1 foot in length, and there is not a vestige of fruit on one of the Vines. There can be little doubt that these air-roots have, in a great measure, brought this about, and if their influence in this case has been antagonistic to fertility, it may be assumed that they will

always produce effects which will be more or less injurious in proportion to the frequency of their occurrence, for the nourishment which supports these roots, or other superfluous growths, is that which should properly go towards the formation of fruit-bearing wood. Air-roots should, therefore, be regarded and treated as any other Vine disease. They are the production of an imperfect root-action in the first place, and a damp atmosphere encourages their growth afterwards. Young Vines are not so liable to become affected as those that are middle-aged or old. Vines on which the berries shank generally form air roots; but they also occur on those that are quite free from this disease. Their growth is often very vigorous when the Vines are first started, especially if they are kept close; afterwards, when more air is admitted, their points get starved, and further growth ceases; where this is the case, they do not do so much harm as when they continue growing throughout the season; and this they always do if not checked in time. Cutting, or rubbing them off, when they are growing vigorously, does no good. The points do not start into growth when once broken; but a second batch is invariably pushed from the base of the first. It is as well to let those that do appear remain and grow until the end of the season, when they may be cut away with a sharp knife while pruning. Vines with their roots in borders which are damp, or in which all the fibre of the soil has decayed, generally produce plenty of air roots, as a close, adhesive soil is not by any means conducive to the healthy development of any Vine. When air-roots appear in quantity no time should be allowed to pass without making an examination of the border. Fresh drainage, where necessary, must be resorted to; and a quantity of fibrous turfy and lime rubbish is of service in sweetening the soil. T.

NOTES AND REPLIES.

Frosted Pears.—It is but too evident that a large number of the fruits found on Pear-trees will presently fall and thus lessen the season's crop. All these imperfect fruits are more or less deformed when closely examined, and in every case when pinched are found to be hollow and black inside. It is very likely that the injury thus evidenced is greater in some varieties than in others, and more or less according to position and surroundings. Readers who may presently find their fruits falling in this way may rest assured that the producing cause is lost, which literally destroyed the organs of fertility in the flower, but left the flesh-forming part of the fruit sufficiently alive to enable it to form a coating over the injured organs, and thus temporarily hide the mischief done and the blackened decay.—A. D.

Gooseberries and the late frosts.—That the Gooseberries have suffered from frosty nights and cold, cutting winds is, unfortunately, only too apparent in the reduction of what was once a promising crop by, in some instances, quite one half. Some districts have suffered more severely than others. While in my own case there are but few fallen berries, a near neighbour bewails the loss of quite half his crop. In his case the garden lies much lower than some, though there are trees and garden walls that afford them shelter. Some of the frost trouble in this instance I am inclined to think is due to the thinness of foliage on the trees by the loss of so many buds by the birds, notably bullfinches. These are a pest in some gardens, and do not confine their attention to Gooseberry-trees alone, but for a change of diet they take Plum, Pear, Damson, Medlar, and Peach buds. I had not learnt of a case of Peach loss until this past season, then I saw the mischief, which if allowed to go unnoticed would soon have spelt ruin to this crop. Fortunately a gun was available and their depredations stayed in time. Gooseberries, however, fared worse, and to this I have come to regard some of the frost trouble, because there was insufficient foliage to shelter the berries. Some kinds, too, seem more liable to injury than others. The loss is accentuated from the fact that the fruit had become of a good size, showing the damage inflicted to be from recent frost.—W. S.

TREES AND SHRUBS.

THE JUDAS TREE (CERCIS SILIQUASTRUM).

The *Cercis* is a picturesque tree, not tall, but spreading out into a head of quaint aspect, and the purplish flowers are produced profusely on the old wood. It is when standing by itself that the full character of the tree is revealed, not when crowded up amongst a host of other things, and deprived of light, air, and space. It was introduced from Southern Europe in 1596, and to get the tree in full character it must be left to grow to old age, as then it assumes its picturesque character. Unfortu-

leaves of a deep green colour. The flowers are deep rose and larger than those of the other kinds.

NOTES AND REPLIES.

The Nepal Laburnum (*Piptanthus nepalensis*).—This cannot be regarded as thoroughly hardy in all parts of England, and it is consequently often trained to a wall, in which position it is now flowering freely, and from the showy character of its golden blossoms it forms a bright and effective feature. It is commonly known as the Nepal Laburnum, which name conveys a very good idea of its general appearance, but the individual

common with most of the Brooms, flowers very profusely. It is of a low, spreading habit of growth, and the long slender shoots are clothed with neat pinnate foliage and studded for a considerable distance with purple Pea-shaped blossoms. It is at home on a sunny ledge of the rockwork, or it may also be planted in the foreground of larger forms. The purple-flowered Broom is frequently grafted standard high, and in this way the long arching shoots are seen to advantage; but even then it would be by most people preferred when allowed to assume its natural character as a low spreading shrub. Not only does this Broom flower in the spring, but a few scattered blossoms are often produced throughout the summer.

Ceanothus.—These are among our best flowering shrubs during May and the two succeeding months, and while not quite hardy, many of the varieties will thrive and flower well if given a place on a warm wall, even in the north with a little protection during severe frosts and early spring, when growth begins afresh. In Devon and Cornwall several of them flower profusely planted in the open. *C. rigidus*, one of the first to open its flowers, which are of a pretty blue, makes a good bush. *C. Veitchianus* against a wall is a lovely thing, and should be included in the smallest collection. *C. azureus* is paler in colour than the two former, but none the less pretty. *Gloire de Versailles* is a form of *azureus*, and certainly an improvement on the type. *C. papillosus* has blue flowers, produced in dense clusters, and *C. floribundus* is a rich blue, while among the white-flowered are *C. apicatus*, *C. collinus*, *C. divaricatus*, *C. integerrimus*, *C. microphyllus*, and several others, but the above comprise the cream of them. They are not fastidious as to soil, but certainly do better where it is fairly light and well drained. On heavy soils it repays to add a little peat. Very little pruning is necessary, and what is should be done as soon as flowering is over. This shrub can be increased by cuttings taken in autumn, and placed in cold-frames similar to *Veronicas*, or shoots may be layered where it is convenient to do so, good plants being quickly secured in this way.—J. M. B.

The Judas-tree (*Cercis siliquastrum*) at Dulwich College.

CHRYSANTHEMUMS.

Early-flowering Chrysanthemums
Crimson Pride and Queen of the Earlies.—These are two of the most useful of the early varieties, blooming in September, and, being under 3 feet, may be planted in a mixed border. Crimson and white respectively, they are conspicuous in the garden when in flower, and bloom very freely. I grow them and stop them in June, thereby getting dwarf plants laden with flowers all through September.—TOWNSMAN.

Pompon Chrysanthemums.—In houses where accommodation is one of the first considerations many admirers of Chrysanthemums are prevented from growing either Japanese or incurved, and either overlook or fail to appreciate the beauty of Pommpons. For the beginner with his small house Pommpons offer several inducements, because they may be bloomed in rather smaller pots than the aforementioned, and can be grown plunged in the border or planted out until towards the middle of September and then potted without any great harm resulting, thereby saving much time and attention during the hottest weather. As a rule, a few sorts of Pommpons in a collection are considered sufficient, but wherever they are grown the following sorts are worthy of mention:—Early-flowering for blooming in the open: Longfellow, white, August; Mme. E. Lefort, amber, Mrs. E. Stacey, apricot, Jacintha, deep lilac, Mignon, golden-yellow, Anastasio, light purple, Toreador, reddish-bronze, La Petite Marie, white, September; Precocite, yellow, Precocite, crimson, Alice Butcher, red, October; Seur Melanie, white, Rubrum perfectum, purplish-crimson, Florence Carr, deep bronze, October and November; Mlle. Marthe, white, Rose Treveuna, rose, November; Mrs. Waterer, pink, Perle des Beauties, crimson, W. Westlake, golden-yellow, tipped red, November; Snowdrop, white, November and December.—TOWNSMAN.

nately, growth is not very rapid, but flowers are plentifully produced on young specimens. The *Cercis* grows freely on all ordinary soils, and many fine specimens, as in our illustration, occur in the older English gardens.

C. CANADENSIS (the American Judas-tree) has an irregular rounded head and cordate leaves of a fine green colour, whilst the flowers are pink, borne profusely, and appear before the leafage. A popular name for it, besides American Judas-tree, is Red Bud, in allusion to its flowers. This species is not common in English gardens, but it makes an attractive feature, especially when planted singly to show off its characteristic features.

C. JAPONICA (the Japan Judas-tree), which is synonymous with *C. chinensis*, is a useful, small tree, the head rounded, and the collate-

flowers are larger, and the trifoliate foliage is of a very deep green tint. In mild winters it is often almost evergreen in character, while if the weather is severe it becomes quite deciduous. Where this *Piptanthus* is not hardy enough to be planted in the open it should not be trained to low walls, as it is such a vigorous grower that continual cutting will be necessary to keep it within bounds, and consequently very few, if any, flowers will be produced. On a wall 10 feet or 12 feet high it will, however, flower freely—that is, if given a southern aspect.

Cytisus purpureus.—If only from the fact that the blossoms are so widely removed in colour from those of all its allies, this Broom would merit notice, but in addition to this it is a really pretty little shrub, and one that in

ROSES.

HALE-STANDARD TEA ROSES FOR POT CULTURE.

To obtain the exquisite Tea and Hybrid Tea Roses in greatest perfection under glass, one must resort to half-standard plants. Good, thrifty one-year-old trees potted up in October and kept outdoors for twelve months make the best specimens. Avoid plants with old, ugly knobs, but select rather those trees that possess abundance of fibrous roots. The Brier itself should not be old. I prefer those quite thin but well-ripened Briers, which one may obtain by diligently seeking for them, but the thin, pithy Briers are worse than useless. Some of my most magnificent Teas this year have been produced on standard plants. What a lovely Rose Climbing Niphetos is grown in this way, so also is the Catherine Mermet race, such as Bridesmaid and The Bride. Twelve splendid flowers upon a three-year-old tree of L'Innocence have been much admired. It is a glorious Rose of very delicate milky white colour, full, but not too double. The flowers expand very freely, and they are of beautiful form. Medea is always fine on standards and half-standards, and as for Maman Cochet, it outrivals all pink Tea Roses. I rather prefer Teas to Hybrid Teas for pot culture in half-standard form; they make graceful, half-pendulous heads, elegant in appearance. Many find a difficulty in properly training a standard Tea Rose. It is very essential that the growths should have plenty of air and sunlight. I use No. 16 galvanised wire for training out the growths. Secure a wire to the stem of the Rose as near the base of the head as practicable, then bend the wire according as one desires the shoot to grow. A fine spreading head consisting of eight or ten growths may be thus obtained by allowing a wire for each shoot. Rosa.

THE AUSTRIAN BRIERS.

How the name of "Austrian" became attached to the group known as *Rosa lutea* is a mystery. I cannot find any reference to this in any of the botanical works consulted, and I should be glad if any readers of GARDENING could throw any light on the subject. Professor Crépin, in his classification of Roses, which he contributed to the last Rose Conference in 1889, mentions Miller's name in connection with *R. lutea*, and puts the discovery of it in 1768. Linnaeus named it *R. Eglanteria*, and Hermann *R. fedida*. It is quite one of the best single Roses grown. The intense yellow colour makes it a prominent feature among the early-flowering species. The Austrian Copper is a variety of *R. lutea*, and is known as bicolor and also as *punicia*. Its flowers are of a marvellous colour—a rich reddish-copper. The full beauty is seen when sprays are cut in the bud stage and allowed to develop in water. It makes an interesting pot plant, also as a standard it is good. The late Lord Penzance used this Rose in the production of his hybrid Sweet Brier Lady Penzance, which is readily seen by the reddish wood.

There are two double forms of *R. lutea*, one known as double yellow or Williams', and the other as Harrisonii. The double yellow is often sold as the Yellow Scotch, and Professor Crépin considers that we owe this to the crossing of *R. pimpinellifolia* and *R. lutea*. Harrisonii was raised in America in 1830. It is an abundant and early bloomer, with pretty buds and flowers of a bright yellow colour. It is, perhaps, the freest-growing of the group, with wood plentifully covered with hedgehog-like prickles. Harrisonii is admirably suited for hedges, and also to form pendulous headed standards. It has a sweet fragrance, quite distinct; the scent of the Sweet Brier can also be detected in the foliage. The Persian Yellow is yet another double form, and is perfectly distinct, the colour of the deepest yellow. It was introduced from Persia by Sir H. Willock in 1837. M. Pernet Ducher has lately given us a lovely hybrid of this latter Rose. It is named Soleil d'Or, and was mentioned in GARDENING on April 12 last. I look forward to a most interesting race springing from this hybrid. *R. sulphurea* and *R. hispida* are grouped by some botanists with *R. lutea*, but the

authorities make *R. hispida* a distinct species, and *R. sulphurea* they class with *R. hemisphaerica*.

All the group should be very sparingly pruned, as they usually produce their flowers at the middle or top of the last season's shoots; but the plants should occasionally have some of the oldest growths cut out. Rosa.

NOTES AND REPLIES.

Niphetos as an outdoor Rose.—Although this is one of the grandest white Roses for indoor blooming, and in rare instances one hears and comes across it growing out-of-doors and flowering, Niphetos, I fear, has not sufficient robustness about it to be ever regarded with much favour as one for outdoors. There is, I believe, some difference of opinion with reference to the pedigree of it, but, be what it may, one cannot compare it with some of our hardier Hybrid Teas. Mine were planted on a south border, having regard to its tender qualities, but I have never been successful with Niphetos outside. Can anyone report better after such a spring as the past? —WOODBASTWICK.

Climbing Roses in pots falling.—Will you kindly tell me what to do to some climbing Roses in 5-inch pots, twined round sticks, in a cold greenhouse—a Niphetos, W. A. Richardson, and Gloire de Dijon? They were bought last March, and were very healthy. The leaves and buds fall off before they come to any size, and in the case of the Niphetos it is quite bare of leaves, and the wood is going hard and dried. The W. A. Richardson has been the best, having had some small blooms, but does not now look very healthy. I shall be pleased if you can help me in the matter. —Dox.

[Yours is a very good method of training certain climbing Roses, and succeeds well after the plants have produced some good lateral. But Roses so trained must have thoroughly healthy root action. It is impossible to say without seeing the plants what has brought about the falling of the foliage, especially in the variety Climbing Niphetos. It is not a kind we should select to cultivate in a cold structure. It is not so much in the spring that climbing Roses miss a warm atmosphere, but from May to July they require it, and a moist atmosphere is necessary, so that the plants can make new wood for next season. We should advise you to repot the plants at once, and, when so doing, examine the ball of earth. If very hard, just press it a little to release the roots, and then repot into next size pot, using a compost of loam two parts, rotted manure one part, with a liberal dash of silver-sand. Pot firmly, and return the plants to your greenhouse for the summer, standing them upon inverted pots.]

GARDEN PESTS AND FRIENDS.

A CURE FOR CANKER IN FRUIT TREES.

I ONCE read in some garden publication of a remedy for canker in Apple trees. It consisted in covering the cankered part (after removing the canker entirely) with a paste made of clay mixed with chlorody acid. I used this method in so far as I applied the acid pure after cleaning away the diseased part, and having effected a complete cure with a single application, I can now recommend this method as both easy and effective. Apply the acid with a small brush, which anyone can make out of horse-hair or bristles from an old broom, or even with a feather. The acid will be found destructive of canker fungus. Possibly it is not absolutely necessary to remove the rough pieces, but I think it better to do so, as it gives a flat surface, and, moreover, the wound will heal quicker. It need hardly be said that care must be taken in handling a corrosive substance like this for the sake of one's clothes as well as one's face and hands.

G. D. HURT (*Revue Horticole*).

THE VINE-WEEVIL (OTIORRHYNCHUS SULCATUS).

SEVERAL of the readers of GARDENING appear to have recently had plants suffering from the attacks of the grubs of this insect, which belongs to the very numerous family of weevils, so many of which injure vegetation in various ways. Most insects are only injurious during one stage of their existence, but in the

case of this insect both the beetles and grubs are very destructive to living plants. The grubs, however, are much more mischievous than their parents, and are only too frequently found destroying the roots of various plants cultivated in pots. When these plants begin to droop and wither without any apparent cause, the presence of these grubs may be suspected; and if they be the cause of the mischief, the roots of the plants will, on examination, be found to be considerably gnawed or eaten nearly through, generally just below the surface of the ground. Cyclamens, Primulas, Saxifrages, Sedums, and other succulent plants, Trollises, Adiantums, Strawberries, and Vines are the plants which suffer most from these grubs. The most certain way of getting rid of these pests is to repot the plants affected, taking care that none of the grubs are left among the roots or earth replaced in the pot. If repotting for any particular reason is undesirable, the roots may be examined by uncovering them as much as possible, for the grubs are generally tolerably near the surface. Watering the roots with an infusion of Quassia or Tobacco-water has been recommended. The weevil at times does considerable damage to Vines, Peaches, and Roses by feeding on their young shoots. They are very difficult to find on account of their dark colour, and of their habit of only feeding at night, remaining hidden in some shelter during the day. They may, however, be caught an hour or so after dark by spreading white cloths under the plants, into which the beetles will fall when the plants are shaken. These cloths should be spread while it is still daylight, as the beetles often drop from the plants on the sudden introduction of a light. The weevils make their appearance in June, and should be destroyed as soon as possible, so as not to give them an opportunity of laying their eggs. These are probably deposited below the surface of the earth, near or on the roots of the plants on which the grubs are to feed. At first the damage caused by the newly-hatched grubs is not noticed, but in the autumn, when they have increased considerably in size, they should be searched for carefully, if there be any reason for suspecting their presence, as it is during the winter and early spring months that they do most injury. In May they descend an inch or two into the earth, and there form small smooth chambers or cells, in which they undergo their change to the chrysalis state. In this state they remain for about a fortnight, at the end of which they leave their chrysalis cases and come forth perfect weevils. They are now about $\frac{1}{2}$ inch long, and entirely black in colour; the head is produced into a long snout, with a deep longitudinal groove or furrow down the middle, the tip of which is furnished with a pair of long antennae consisting of twelve joints; that nearest the base is very long and somewhat curved; the remaining joints are small, and form quite an elbow with the long joint, the four nearest the tip forming an oval knob. The thorax is broadest in the middle, where it is considerably wider than the head; it is covered with small, raised tubercles. The wing cases are much wider than the thorax and are oval in form, being broadest about the middle; they are much rounded transversely, and are sparingly sprinkled with small brownish spots composed of minute hairs. The legs are strong and of medium length; the thighs of the front pair are much thickened towards the knee joints, and are each armed with a strong tooth. The grubs are about $\frac{1}{2}$ inch long, and are generally in a somewhat curved position; they are stout, fleshy, much wrinkled, considerably thicker in the middle than at either end, and are entirely destitute of legs. The joints are thirteen in number, well defined, and of a dirty white colour, sparingly covered with stiff, brownish hairs. The head is reddish brown, and furnished with a strong pair of jaws.

Broad Beans falling.—I enclose roots of Broad Beans, of which the crop has entirely failed, the blossoms and pods turning black and rotting. Have the correspondences on the roots anything to do with this? I have never seen anything like it before. —E. P. W.

[I cannot in any way say what is the cause of the failure of your crop of Beans. I can only give you a negative reply that the

erescences on the roots are not the cause. They are formed by one of the Bacteria (Bacterium radicola). Peas, Beans, and other leguminous plants require a large amount of nitrogen, and these bacteria, in some way which is not yet quite explained, enable them to make use of the nitrogen of the air, which they are not able to do when these nodules are not present on the roots. From the size of the tubercles I should imagine the soil in which your Beans grew was deficient in nitrogen.—G. S. S.]

GARDEN WORK.

Conservatory.—Berry-bearing Solanums are useful in winter. We generally plant out about half our stock, and lift them in September. The other half is grown in pots. We find the potted plants ripen their berries a little earlier than those planted out, and so a succession is formed. Those that are planted out are in an open situation fully exposed, and they always berry well. The potted plants are in a cold pit with the lights off, except during heavy rains. We keep them in the pit because the wind has less effect upon them. We find Eupatoriums do best planted out. They are pruned hard back in April, and by the end of May they have broken well, and when planted out they grow freely and are pinched once in July and lifted in September, and placed for a few days in a shady position on the north side of a wall. They are well in flower by Christmas in a cool-house, and come in useful after the bulk of the Chrysanthemums is over. We have had large bushes in 8-inch and 9-inch pots. Mignonette sown two or three seeds in small pots in April, all but the strongest removed, and grown on through the summer, trained either as pyramids or standards, shifted onto larger pots as required, and all flowers picked off, will make large flowering bushes by winter. A large-flowered variety should be selected, as otherwise the blooms on a much-potted plant will come small. When the pots are well filled with roots, liquid-manure can be given. Though Mignonette is generally regarded as an annual, it is not necessarily so, but of course the older the plants the smaller the flowers. We have had Mignonette planted in the borders of a conservatory assume a shrub-like habit with woody stems, but when that stage is reached the flowers come small and are less fragrant. The ventilation should be free, even in dull, damp, sunless weather. We never remember a June so sunless and damp as the present. We have discontinued fires in all plant-houses except the warm stove, but damp is kept down among the flowers by a free circulation of air, of course keeping out heavy rains. Under such treatment the flowers open slowly, but they last longer. There are beautiful things among the newer Ivy Geraniums. Some of them planted out and trained up against bare places or walls or pillars are very effective. Leopard is a very distinct spotted variety. Resplendent is very bright and showy. Among Zonals, Rudyard Kipling, a rich purple, and Ian McLaren, a massive salmon-coloured flower, should be added to every collection.

Hard-wooded plants.—We have delayed turning these out in consequence of the heavy rains, but by the time these lines appear a change may have come, and Azaleas, Camellias, and other hard-wooded stuff will be outside. This annual outing is always beneficial under favourable conditions. Camellias must be in a shady spot, or the hard shining leaves may suffer. Azaleas and New Holland plants will do in the sunshine if the roots are sheltered from the hot sun. They may be so arranged that the foliage of one may shade the roots of the next row of plants. It is not always convenient to partially plunge in ashes. This, where it can be done, keeps the roots from drying so fast, and acts as a support against wind. I have sometimes sheltered the pots on the sunny side by placing Moss against them, where Moss was plentiful. The sunshine will ripen the wood if the roots are kept right. The syringe should be used daily in the afternoon, and special care must be taken with the watering. Never trust a showery time to supply enough to a well-rooted plant.

Young plants in frames.—All kinds of young plants, even young stove things, and especially Ferns, will do better in frames than in houses till the middle of September, as appearances with us are not so much studied. We simply mix a little size and whitening, and either rub a little of the mixture, after making it thick enough, on the glass, or strain it and pass it through the syringe. If the frames can be placed where the midday sun will not reach them, there will be no necessity for shade in any other way. The necessary pinching should be given to Begonias and other winter-flowering plants, except, of course, Poinsettias, which must be built up sturdily but not pinched. Ventilation must be given to harden growth, and the plants shifted into larger pots when necessary. Cyclamens and Primulas will be in frames now, freely ventilated and slightly shaded when hot at midday, dewing them over with a fine syringe every afternoon, and always giving night air freely in suitable weather, but keeping off heavy rains. Cyclamens must have clean, well-drained pots and good soil. We are potting ours in two-thirds best turfy loam, the remainder composed of peat, leaf-mould, and sand, with a dash of soot. Any stimulant will be given later on if required when their roots have filled the pot. The bulk of the plants will be in 3-inch and 6-inch pots. A few old corms will be grown to a large size in 7-inch and 8-inch pots. The loam, being the main staple, must be good and turfy, with some body in it.

Late Grapes.—These have required fires up to the present, as the nights, and in many cases the days, have been cold, and it is better to use fires now and get the crop forward than use more fire heat later, when the sun will not give much help. Stimulants should be given from this till colouring commences. Vines in a well-drained border will take a good deal of feeding, and something that acts quickly is best now. Liquid-manure from a yard, if available, will do, and, failing that, some artificial manure may be mixed with the water or be scattered over the border, 2 ounces to the square yard, and watered in. The border may have two dressings of this strength at intervals of three weeks or so.

Window gardening.—Musk is a favourite window plant. There are several Campanulas very pretty for windows from this onwards. *C. garganica* is now in flower. *C. isophylla* (blue and white) flowers a little later. Tuberous Begonias, Oak-leaved Geraniums (including the variegated Lady Palm-mouth) are sweet things in a room. If Palms or any other fine-foliated plants require a larger pot, the shift should be given now, the plants to be watered with caution after repotting.

Outdoor garden.—When climbing Roses, Jasmines, and Clematises are obtained in pots, June is a good month to plant; or, in fact, any time during summer, as they then get established before winter. In spite of careful planting there will be occasional deaths. Among Clematises of the large-flowered type, *Jackmanii superba* is one of the hardiest and best, and *Henryii* the best white. Some of the newer forms are very beautiful, including double white and double mauve; but grafted plants are not equal to plants obtained from cuttings and layers. This may partly arise from the union being unhappy; even when the grafting has been skilfully done there will be failures, and these Clematises are so lovely one wants them to live and thrive, and to this end, when planting, place a little good soil round the roots, but no manure, though a mulch on the surface will be helpful. A mulch of good loam over the surface of Carnation beds will be better than manure, and will keep the moisture in the bed, and, by adding some sand to it later, will do for the layers. Flower-stems must be staked, and, if fine blooms are wanted, the buds thinned. All flowers are later than usual at present, though a week's bright sunshine will bring things on with a rush. The necessary staking of certain plants, and pegging down of others, should receive prompt attention.

Fruit garden.—It is important for Strawberry runners to be obtained early for forcing. They may either be laid on the top of small pots filled with good soil and secured with a

peg or a stone, or be laid on the fruiting pots at once. We adopt the small pot system and consider it the best. For planting new beds we have laid the runners on small mounds of good soil. The stronger the plants when put out the better the crop next season. The Gooseberry caterpillar must be watched for and destroyed. There are several ways of doing this. If there are only a few insects, hand-picking will be best, because it will not disfigure the fruit. Hellebore-powder may be used in bad cases, and may be mixed with water and applied with the syringe. Very often at this season Red and White Currents are attacked by the Currant aphid, which speedily curls up the foliage and injures the fruit. These insects always begin at the ends of the shoots and work downwards, and if the ends of the shoots are cut off and removed, this trouble may generally be got rid of easily. The shoots of Morello Cherries are often at this season attacked by black aphides. Dusting with Tobacco-powder, or mixing Tobacco-powder and soft-soap in water and dipping the infested shoots therein, will clear them. Two oz. of soft-soap and 1 oz. Tobacco-powder to a gallon of water will do.

Vegetable garden.—The weather has been wretched for some time, and there will probably be in many gardens arrears of planting, and especially weeding and hoeing, to fetch up. The season is moving on, and Celery, Winter Greens, and various other things, including a good breadth of Turnips, should be sown or planted. Lettuces, also, and Endive should be sown for late summer use. Late Cauliflowers should be planted, and a good batch of Veitch's Self-protecting Broccoli set out. A further sowing of Peas may be made, but the kind should be a second early one. French Beans should be planted in succession. The Runner French Bean is useful for summer use. Tomatoes outside should be secured to the wall and the side shoots snipped off. If planted in the open, select a sunny spot, and make a trellis of Bamboo-canes. We are growing open-air Tomatoes largely, but shall stop when three trusses have shown, as in a backward season, if we get three clusters of fruit we shall be satisfied. Top-dress Cucumbers frequently, and give liquid-manure when help is wanted. Keep the growth thin by pinching regularly one leaf beyond the fruit. We hear of a good deal of disease among Cucumbers under glass. E. HODDAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 7th.—Sowed Wilton 1st and Laxton's Improved Peas. Sowed Canadian Wonder Beans for the last time; shall sow an early kind later. Brussels Sprouts, Broccoli, Kale, and late Cauliflowers have been planted. Made several Mushroom beds on the north side of a wall, sheltering with litter and waterproof cloth. Peas are gathered as soon as the pods are full enough. The leaves are tied over Cauliflowers as soon as the heart is visible.

July 8th.—Tomatoes are allowed to hang on plants till ripe—it improves the flavour. A little air is left on fruit-houses all night, except in wet and windy weather. Liquid-manure or stimulants in some form is given to inside borders of Grapes, Peaches, and Figs. The fruits of Melons are set when the pollen is dry in the forenoon. An effort is made to get all the crop set at the same time, as far as possible, so that all may swell together. Thinned and stopped Cucumbers in houses.

July 9th.—Moved a lot of *Lilium longiflorum* and *aureum* just opening their flowers to conservatory. The stamens are always taken out of Lilies before the pollen is ripe, otherwise the flowers are too much stained for any decoration in a cut state. Shifted on a lot of young Acacias and other hard-wooded plants. A little loam is used in the compost for Acacias, but for other things, chiefly pent. Moved Azaleas to coal-ash-bed, the pots being plunged in ashes.

July 10th.—Put a tie to Dahlias, Hollyhocks, and other things requiring it. Thinned the buds of Carnations a little. Sowed Chervil, Turnips, Lettuces, Endive, and small saladings, the last in the shade. Sticks are placed to

Peas in good time, so that the tendrils may have something to cling to. Moved a few flowering and fine-foliaged plants from stove to conservatory to make room for growing specimens. Pricked out Canterbury Bells, Sweet Williams, and other hardy seedling stuff.

July 11th.—Pricked out more Celery. Looked over late Vines to stop sub-laterals. Tied in young wood of Peaches in late house. Gave a final thinning to young wood of Peaches on walls. One or two trees that had blistered leaves have recovered, and are now making healthy growth. Finished thinning fruit on Apricot trees. Stopped young shoots of cordon Pears on walls. One or two Plum-trees which were attacked by insects have been syringed with Quassia.

July 13th.—Scattered nitrate of soda over Asparagus plantation during showers. Weeds are kept down by hand-picking and hoeing between the rows. Cut Box-edgings in showery weather. Gave final thinning to Onions. Lettuces are tied up when dry in relays as required. Thinned out Endive to 15 inches apart. Some of the young plants have been set out at same distance elsewhere. The hoe has been freely used when the surface has been dry.

POULTRY.

Roup in fowls (Rustic).—Several prescriptions for roup pills might be given, but none is better than the following: Cayenne pepper 20 grains, copper sulphate 10 grains, cohiba 1 fluid drachm, to be made into 20 pills, one of which should be given to an adult fowl night and morning. The fowl should receive half a teaspoonful of Epsom salts before the first pill is administered, and its head and affected organs should be washed twice daily with Labarraque's solution of chlorinated soda, diluted with twice its bulk of water.

Hens dying (Hen).—You are evidently feeding too highly, and we should advise adding at least one-third of pollard or sharps to the morning feed of Barley-meal and discontinuing the Potatoes, as these are also fattening. It is always better to underfeed than to give too much, as when a hen becomes fat she ceases to lay. Overfat birds suffering from liver complaint often die suddenly from the rupture of a large blood vessel in the neighbourhood of the liver, and this disease when once firmly established is incurable, the only remedy being to clear out the old stock and start afresh, as liver disease is hereditary. There is no doubt your hens obtain much food in the form of worms and so forth in the field where they run, notwithstanding which they would always be ready and anxious for their food at meal times. It would be also well to vary the grain food, giving from time to time a little Wheat or Barley.—S. S. G.

BIRDS.

Red Linnet (Mrs. A. Ridgway).—Your bird is no doubt suffering from a disease of the skin, and from your account of its condition is not likely to recover. Anointing the affected part with a little neat's-foot oil or vaseline would give relief, but it would be better to destroy it at once rather than let it suffer. The sample of seed contained a large proportion of Hemp, and there is no doubt that partaking too freely of the latter has brought about this trouble. The best food for these birds is Rape-seed, with a small quantity of Canary seed, and green food occasionally, such as Lettuce, of which they are very fond. Little or no Hemp should be given, as Linnets are subject to excessive fatness of the internal organs. To keep them in good health a little salt should be given now and then.—S. S. G.

Death of Bullfinches (Zitella).—In both cases there was a large clot of blood in the region of the heart, and this would indicate that their sudden death arose from fright. Bullfinches are very susceptible to the influence of heat, and as your birds were with foreign linnets and Canaries, the temperature of the aviary was probably higher than

was suitable for them. This would tend to bring about heart weakness, and render them liable to sudden death. But their both dropping off at the same time would appear to point to their having been alarmed. Then, again, in the matter of food, the seed supplied to foreign birds would not be quite suitable for Bullfinches, the best food for them being the larger kind of Rape-seed, but scalded to remove its acidity, and a little Hemp. The hen bird was very bare of feathers, and the under parts of the wings of both were quite denuded, having been picked bare by the birds themselves. The cause of this was in all probability through their having been attacked by parasites, although an over-heated atmosphere, causing an irritability of the skin and a gross condition of the system, would give rise to the habit of feather-eating.—S. S. G.

Treatment of Bullfinch (W. L.).—From your bird being very wild it has probably been lately captured. It will, no doubt, become tame in time. I should advise you to keep it indoors that it may become accustomed to human society. As a rule, Bullfinches become very tame and familiar in captivity. If you wish to prepare your bird for exhibition, you must take care for one thing that the allowance of Hemp-seed is very limited, as the free use of this will often cause the plumage to become dark. From twelve to twenty seeds a day should not be exceeded. Scalded Rape-seed is the best staple food for these birds. To this may be added a small allowance of Canary-seed, and for green food give a few twigs of some fruit-tree, with occasionally a stalk of ripe Plantain-seed, a few Privet-berries, a little plain biscuit, a piece of Apple, or a little Watercress. You are quite right in putting a nail in the drinking-water, as this provides a mild tonic and tends to keep the bird in health.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, FURNIVAL-STREET, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Repotting Roses (Paddy).—No. Stand in full sun on a bed of ashes, and if the weather is dry they must be watered with a rose-can after the first three or four days, but only resort to artificial watering when really necessary, or the soil becomes too much compressed for the new roots to work into it freely.

Carbonate of lime (Subscriber for Years).—Lime is useful for many purposes, and the carbonate of lime that you have is of value. Its action is similar to that of quicklime, though the latter is much more powerful. Much of the value of lime is due to its mechanical action on the soil; it makes heavy soils more friable and light soils more cohesive.

Palms for a greenhouse (T. H.).—The following half-dozen to begin with should suit you: Kentia Forsteriana and K. Belmoreana, Phoenix reclinata and P. tenuis, Rhapsis humilis, and Livistona chinensis, better known as Latania borbonica. Licualas will not thrive in a root-house, neither will Stevensonia. The plants will all grow well in loam and peat made sandy, and the pots require thorough drainage.

Six Roses with deep petals for cool greenhouse (G. W. S.).—The following would, we think, meet your requirements: Anna Ollivier, Mme. Hoste, Mrs. W. J. Grant, Marquise Lilla, Maman Cochet, and Killarney. If you have not already set your plants outdoors to ripen, this should be done at once; but we should recommend you to plunge the pots in some ash to prevent too rapid evaporation, and if the plants are small keep all flower-buds pinched off during the summer.

Rose-leaves curling (Rosa).—There are several causes for this. Rose-leaves curl because maggots have taken up their residence in them, and the action of the insects provokes this curl. They also curl from the action of green-fly or aphids, and also from cold, cutting winds. They sometimes also curl from drought at the roots. If

you think the roots are dry, give them a good soaking of water, and also some manure-water, and cover the soil over with some half-decayed stable-manure. To induce new and robust growth is the best thing to do now.

Sowing seeds of hardy perennials (S.).—The following may be sown in July and August. All such seeds may be sown as soon as ripe, that being their natural season: Lupinus polyphyllus, Lupinus macrophyllus, Foxglove (spotted varieties), Dictamnus Fraxinella, Linum perenne, Delphinium formosum, Veronica spirata, Linnaria biennis, Columbine, Antirrhinum, Anemone italica, Rudbeckia Neumann, Campanula pyramidalis, Campanula nobilis, Alyssum saxatile, Viola and Pansies, Ibericum Chusii, Prunella japonica, and others. Dracocephalum austriacum, Trifolium repens, Hollyhock, Sweet Williams, and Centaurea montana.

Blood-manure (Ken).—This needs such care in using that we do not set much value on it. If used in excess for Roses and fruit trees it causes them to make a lot of sappy growth that is not desirable. In using blood, add six times its bulk of dry soil, and keep it under cover, turning the mixture once a week. For plants in pots it is best mixed with the potting soil, at the rate of one-sixth to the bulk. For outdoor crops it should be spread on the surface and forked in. One cubic of the mixture to every square yard of ground is a liberal dressing. For whatever purpose, you should advise amateurs to rely on good rotted stable or farmyard manure.

Flowers in May and June from seeds sown now (W. L.).—Celsia cretica, Apollonia hybrid, Foxglove (blue and white), Campanula in variety, white and blue Lupinus, Sunpapers, Tree-Lupinus (white and yellow), Oriental Poppy, yellow Alyssum, and Euphorbia. These are all excellent for flower decoration, in addition to the list given; they are perennials. "W. L." should add Canterbury Bells (biennials), and get about a hundred cuttings of Mrs. Sinkins Pink; they will root new easily. The Euphemias, besides being graceful flowers, have beautiful foliage, so has Thalictrum—far better than Fern. Yellow Wallflowers are beautiful in early May if grown on a north-west border.—A. B. Dawkins.

Roses not blooming in a greenhouse (R. P. M.).—To flower Roses well they must get plenty of sun, air, and good food, and we should imagine that in this case they do not do so. Very probably the Vines give too much shade, and hinder the wood from maturing as it should do, in which case there is but little prospect of success. We should counsel you to feed the Roses all through the summer with weak liquid-manure. In November thin out the weakly growth, and cut the shoots left back to about two-thirds of their length. The great point is to induce luxuriant growth now, and to ripen the same by exposing it as much as possible to the sun, and admitting air freely during the early autumn months.

Position for cold-frame (Myrtil).—A south aspect, especially under a wall, is certainly much the best position for a cold-frame during the winter, as, apart from other considerations, the plants in it would benefit from the greatest body of light they could secure, as well as a higher average temperature. Hardy plants in such a frame would suffer little if frozen but once, as it would be best to throw mats or litter over the glass to exclude light until a natural thaw set in. Practically, plants would suffer less if, once frozen, they remained so until a true thaw resulted. Were they sometimes frozen and often thawed harm would probably result. Certainly, were the frame covered up well at night the frost which entered would probably be slight and comparatively harmless.

Roses with green centres (E. Terry, M. J. and W. Ripper).—This freak of nature is peculiar to a few kinds, such as Mme. Annie Wood, and where this malformation constantly recurs upon the same plants we should advise you to destroy them and plant popular varieties that are free from such a fault. But whilst these green centres are peculiar to certain varieties, they may, nevertheless, be brought about owing to a check of some kind which the plants receive, such, for instance, as spring frosts or overuses of manure. We fear there will be many malformed buds this season owing to the late frosts and cold, cutting winds. Where possible to detect these green-centred buds, it is a good plan to remove them early and encourage the smaller buds, which may be more perfect.

Artificial manures for plants (Myrtil).—Nitrate of soda is certainly a leaf promoting manure, but when leafage is formed wood is formed also, and that has to be overlooked. Still, all plants, more or less, and according to their structure, need phosphate, potash, and nitrogen, and a mixture of these, which the chemist can plant a complete manure, practically furnishes all a plant requires. The proportions used in the making of liquid-manure should be about equal, such as 6 lb. in 2 1/2 of each, dissolved in 20 gallons of water, and applied to vegetables and fruits twice a week, and to ordinary flowers once a week. For plants, however, will be all the better if supplied twice a week. If, at any time later on the soil becomes very dry, give the crops a soaking of water six hours before applying the liquid-manure. A peck of soil in a coarse bag, soaked with chemical manure, is a valuable addition.

Wild cliff garden (E. W. A. Hastings).—It is not easy to suggest a subject that will outgrow and overcome Couch Grass. It is one of the most persistent of all such in those soils where it most flourishes. Frequently, old roots are trenced in 2 feet deep they do not arrive, and if they do, the only other thing to fork them out and burn them when dry. This may not prove a ready means of destruction, but what one has to fight in these and similar instances is not merely the weed, but the year upon year in the past during which it will have the supreme possession of your now idiosyncratic soil. The feature is that every atom will grow. It would appear your last winter trenching has modified the crop, and possibly what is now appearing may be fragments broken off. We cannot suggest any crop that will choke it, for the roots are not easily overcome. By trenching the soil in 2 feet deep, and giving a heavy dressing of caustic lime in the trench on the roots, or even of salt, it may have the desired effect, though were we in like position we would fork it out and burn it, as the least expedient method of overcoming a terrible garden pest.

TREES AND SHRUBS.

Cutting down Hollies (S. S. W.).—The best time to cut down the Hollies is early in spring before the sap rises. A sloping cut is much preferable to a straight one, as moisture is thus prevented from remaining on the cut portion, and, as an additional precaution, the wound should be covered with a coating of tar. It will be much better to leave the side growths, as they assist to draw up the sap.

Rhododendron flowers changing (H. A. Dwyer).—Your Rhododendrons must have flowered unusually early for the blossoms to be past, the seed pods picked off, and a second crop of blossoms expanded. It is no uncommon thing for a few buds to expand after all the others are past, but the change in colour is difficult to account for. We should be inclined to think that the plant has been grafted, and the shoots now flowering are the produce of the stock, whereas the earlier ones were borne by the scion; that is the true Old Port.

Stauntonia latifolia (C.).—This is a handsome, half-hardy evergreen creeper, native of Northern India, bearing very sweetly-scented flowers, which are, now, however, very showy; still it is worthy of a place in a cool greenhouse. In some of the warmer parts of this country it succeeds well when trained to a south wall in the open air. It may be potted or planted out (the latter is the best way) in a well-drained compost of turfy loam and sand, with some sharp silver-sand added to it. Plenty of water will be required at the root when the plant is established and in active growth in summer, and it should be well syringed frequently to keep the foliage clean.

Wistaria not starting (Wistaria).—The treatment given to your Wistarias could not have been improved upon, and we think it very probable you will find that they will yet start away in a satisfactory manner. By the retransplanting we have had them stand completely dormant till midsummer was past, when they broke out freely and grew rapidly. True, ours were lifted from the open ground, and, therefore, a much greater check was inflicted on them than if simply turned out of pots. Still, your others are rather old plants they may have been to a certain extent starved and the roots cramped, and very likely the minor rootlets are now active; if so, it will soon show in the buds pushing. We should certainly not cut back such plants as you describe. The minor shoots will be back a little; it is the plump buds at the base thereof from whence the new growth is pushed out.

Rhododendrons not blooming (H. R. Mather).—The failure of your Rhododendrons to bloom is in all probability caused by weakness of constitution, which may be brought about in several ways. An unsuitable soil, particularly if it contains lime in any shape, drought, a shady position, or an overcrowding of weak shoots, are likely to bring about such a condition of things as you describe. If this last prevails to any great extent they may be thinned out now, but the question of soils must be left till the autumn. A clay subsoil suggests that the plants are badly drained, and though Rhododendrons suffer greatly from drought, stagnant moisture is equally injurious. You might in the autumn lift your plants and examine the soil in situ, or, if you are not sure, you may dig it up with it, then replant, taking care that the soil is broken down firmly. In doing this leave a hollow a couple of feet in diameter or so around the stem for drainage, and take care that the plants at no time suffer from want of moisture. If the plants are tall and weak you may cut them down to within a couple of feet of the ground, but this is much better carried out in April, though it may be done even now.

FRUIT.

Black Cluster Vine in a cool-house (C.).—This Grape ripens freely in the open air against a wall in the open air in ordinary summers throughout the midland and southern counties. That it ought, therefore, to ripen in a cool-house in the north seems obvious, as in such a structure, though unprovided with artificial heat, the ordinary outdoor warmth would be increased thereby quite a month earlier, and retained quite a month later in the season. We advise you to give both that and the several Muscadine a trial.

Gooseberry and Currant bushes with rank growth (H. E. T.).—Thin out the "rank" shoots now on the Gooseberry and Currant-bushes to let the sunlight and air to ripen the wood, and at the autumn or winter pruning thin out the growths a little if necessary; but do not shorten the shoots of the gooseberries that are left, and then there will be an abundance of fruit. It is a great mistake to prune Gooseberries too hard on strong soils, their strength is checked away in useless wood production when such is the case.

Raspberry-suckers (R.).—The young shoots that spring up from the bottom of the shoots should now be cut out to something near the required quantity. In the case of young plantations that have not yet attained their full strength, two or three bearing shoots will be enough; those that are stronger may have six. In thinning the young shoots it is not sufficient to cut or break them off level with the ground, for if so treated they will usually spring up again. An ordinary planting trowel will be the best implement to use for the purpose, removing 1 inch or 2 inches of soil, whereby the shoots can be taken off directly from where they spring, in all cases retaining the strongest. Keep the ground well hoed, but do not dig it.

VEGETABLES.

Treatment of Cucumbers (C.).—Keep the atmosphere of the house close and moist, and give plenty of water at the roots when the plants get well established. Prick the main shoots up the roof, say for 3 feet or 4 feet, and then stop them. When side shoots are produced, stop them one joint past the fruit, and continue such a practice throughout. When in full bearing, a top-dressing of rotten manure will be beneficial, as will also occasional doses of manure-water.

Spot in Tomatoes (J. Fraser).—Your Tomatoes have been attacked by a fungus known as Cladosporeum lycopersii, which springs from spores floating about in the air. The spores settle on the fruit, and if the house be damp they will at once germinate. Keeping the air of the house dry is a good preventive. Give abundance of

air, leaving some on all night, and see that the roots have a good soaking of water, not a dribbling. Pull off all the infested fruits and burn them.

French system of growing Asparagus (Inquirer).—The Asparagus is planted in a little trench, somewhat like a Celery trench, but not manured as the latter is. After the first year's growth, if the ground is not very rich, manure is added, and a little is given every year. This, with the upward growth of the plants, gradually raises the soil around the collars, and by the time the plants are three years old, and have a good heap of the mould about the crowns, the bed is naturally raised up a little. The trenches should be 3 feet or 4 feet apart.

Turnips bolting (J. J. Whitby).—On some soils raising early Turnips is a difficult matter, as unless carefully managed they may run to seed (which yours have done) at the very time they ought to be ready for use. Under these circumstances, unless your land is very suitable for Turnip growing, April is quite soon enough to make the first sowing. A sprinkling of superphosphate applied when the seeds are sown will push on the crop, and should never be omitted when the fly is troublesome. Sow in drills 1 foot apart, and thin the plants well out. During hot weather the drills should be thoroughly soaked with water previous to sowing the seeds. If the seeds lie too long in the soil the plants always come patchy and weakly. You give us no idea as to the soil, but if it is light the evil you complain of is sure to follow, more especially if you have not thinned out the seedlings freely.

SHORT REPLIES.

E. W. A.—Your Thorns seem to have been attacked by some insect, but it is very difficult to assign any cause of failure without seeing the plants.—W. G. Please send us the double and single forms, and we will try and help you. Possibly some of the single form may have got in.—Mrs. J. Hurdell.—Your Peach-tree leaves are suffering from what is known as blight. See reply to "Major" in our issue of May 17, p. 161.—C. P. W.—The only possible reason we can give is the very cold and unseasonable weather we have had of late.—Bowie.—You had better write to some of our large Rose growers.—S. C.—If you want to cut down your Aralia, the best time is the month of March or early in April, but as this plant is so easily raised from seed we would advise you to get up a young stock, which will be far better in the end.—H. T.—The reply to "M. G. L." referred to Tulip Pansies (Violas). We know of no books dealing especially with

Pansies and Auriculas. "Floralia" Flowers" (it still in print) by Mr. J. Douglas, would help you.—F. W. Davies.—You cannot do better than plant me of the climbing Roses or Clematis, of course putting in good soil in place of that you have, which you say is very poor.—W. F. Smith.—Your best plan will be to dust the plants with Tobacco powder or syringe them with some insecticide.—Mrs. Gray.—The best way is to advertise them in one of the gardening papers.—Norie.—Consult our advertisement columns.—D. W. Hughes.—The best way to kill woodlice is to pour boiling water over them, if you can find out where they congregate. The same will answer in the case of the ants, if you can find out their nests.—Lady Mary Craig.—If your Brier cuttings are well rooted you may certainly bud them, but if not leave them for another year.—Lion.—It is useless to attempt growing any flowering plants under such a roof. You can only grow such as Ferns and Mosses.—K. G. S.—No, they are not the true Mushroom, but resemble the Horse Mushroom (Agaricus arvensis).

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, Pall Mall Street, Holborn, London, E.C. A number should also be firmly attached to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—J. C. T.—Lithospermum prostratum.—R. Pitt.—1, One of the tall Linaria, but impossible to say without flowers; 2, Fumitory (Corydalis lutea);—Sarracenium; 1, Isoketes gracilis; 2, Aloe sp., send in flower; 3, Sedum carneum variegatum; 4, Cyperus alternifolius; 5, Tradescantia zebrina.—Mrs. Hubert Holton.—Rose Gloire Lyonnaise.—Mrs. Sheldon.—Not recognised.—A. Harrison.—One of the many forms of Spanish Iris.—Maud Worth.—Yes, a double-flowered Columbine.—Dun. Cranochilus aureus.—P. L. Smith.—1, Pyrolithum, single; 2, Veronica sp., send leaves; 3, Honeysuckle (Lonicera biennis); 4, Woodruff (Asperula odorata).—Mrs. D. M. Green.—Your plant is, we think, from the description you send, Citrus Upliana, plants of which we have seen growing in the open air in Devon.—Philomathea.—1, Caryx sp.; 2, Festuca elatior; 3, Common Spurry (Spergularia arvensis); 4, Fox glove.—Henry Wilkinson.—We cannot undertake to name British flowers.—H. W.—Auricularia formicoides.—J. Anderson. Hybrid forms of Aquilegia vulgaris.

FRUIT.

MULCHING FRUITS AND VEGETABLES.

In dry weather the value of a covering of some kind of manure over the roots of plants is very great. In the fruit garden Apples on the Paradise and Pears on the Quince will be much benefited by a mulch of good manure 2 inches thick spread on the surface as far as the roots extend. It is difficult to keep the roots sufficiently moist without something of the kind in when water is plentiful and can be easily applied. Watering at any time is not an unusual good. In very dry weather, unless the surface is mulched, the water rapidly evaporates, leaving the surface soil in a harsh, unfavourable condition. Where the appearance of manure is objectionable it is an easy matter to draw away a little of the surface soil and scatter it over the manure. When the latter is applied this will keep the birds from scuttering it about and along the garden untidily during very hot, dry weather. It is next to impossible to keep bare-rooted fruit-trees in really good condition in a dry time without mulching. Strawberries are generally mulched down as early as the blossoms are set, if not earlier, and a mulch of manure or even the lawn mowings scattered between the rows of Raspberries is much to the weight and value of the crop. All trees, especially those trees growing against the walls, often suffer from lack of moisture in June till the crop is ripening, and a mulch will keep the roots comfortable and the foliage healthy and free from red-spider. But as soon as the crop is gathered the manure or whatever dressing has been used should be removed to let the sunshine warm the roots, and by its action ripen the foliage and harden the wood. Young plants cultivated for their flowers only, such as Phloxes, Hollyhocks, Carnations, Pansies, Petunias, Stocks, etc., are much benefited by a surface covering of manure. It is possible, of course, to grow good flowers without mulching, but the soil has been thoroughly cultivated, and there is a great saving of labour in the use of a few loads of manure spread over the roots, and when it is necessary to water during a prolonged drought the nutriment in the manure is turned down to the roots, adding size to the blossoms and health and vigour to the foliage. Well-rotted manure forms the best material for mulching. In many instances, if more hoeing and less watering were done the plants would thrive better. Mere

SURFACE WATERING often does more harm than good, by the encouragement given to the production of surface roots only. The natural tendency of the roots is to go downwards in search of moisture in hot, dry weather. It is in the case of fruit-trees that this downward tendency, if it proceeds far, leads to disorganisation of growth and is destructive of fertility, simply because without warmth as well as moisture the wood will not mature sufficiently to produce fertile blossoms. In extreme cases there may be an entire absence of flowers, and under such conditions there can, of course, be no fruit. Hence the value of a mulch of

manure on the surface over the roots of fruit-trees in hot, dry weather, to keep the roots within the influence of solar heat, so that the wood may be properly built up and matured.

A mulch of some kind, either in the shape of a covering of manure or a loose, freely-stirred surface, is absolutely necessary for most vegetables, but especially Peas, Beans, Cauliflowers, Lettuces, Celery, Globe Artichokes, Vegetable Marrows, ridge Cucumbers, etc. To have Radishes good and crisp in hot seasons they should be sown in drills, and the spaces between the rows covered with short manure. In the use of mulch everybody will, of course, be guided by his own circumstances and the character of the soil he is dealing with. At the present time there are very few gardens with a sufficient water supply to meet a hot, dry summer, and where the water supply is abundant the means of distribution are often inadequate. A few loads of manure will go a long way in mulching, and will keep things up to the mark with an occasional soaking of water. In this island home of ours we never have too much sunshine if the proper means are taken to keep the moisture within reach of the roots.

VINES DUKE OF BUCCLEUCH AND B. HAMBURG FAILING.

Will you have the kindness to let me know what is the matter with the enclosed Vine leaves taken from a Vine called Duke of Buccleuch? The border is inside and outside the house, and is about 15 inches higher than the level of the garden soil. Another Vine in the same house—Black Hamburg—is showing a tendency to have the same marks on its leaves. The other three Vines—Madresfield Court, Gros Maroc, and Buckland Sweetwater—do not show any signs of this withering. The house faces S.E. and is well ventilated top and sides. The Vines are watered every afternoon, and I have examined the bed and found it to be damp, not wet, and the roots making young growth. The Vines were two-year-old canes when planted last winter, or rather this spring. There is one bunch of fruit on Black Hamburg and none on Duke of Buccleuch. There is not fire-heat in the house at present. I am much obliged for the information you so kindly gave me in past issues of your paper respecting Vines and Peaches.—W. M. FANNING.

[Had your complaint referred only to the Duke of Buccleuch Vine, we could have more easily understood and assigned a cause, but for the Black Hamburg to have acted in the same manner reduces the case to one of the insoluble problems so common every day in the garden. There may be local reasons why your Vines have acted thus, which, without some knowledge of the nature and state of the border, and the conditions of the Vines when planted, reduce the possibility of arriving at a satisfactory solution of the case. Your letter states that the Vines are watered every afternoon. This is wrong treatment to give irrespective of the weather, for without fire-heat the watering or syringing would not be favourable on cold nights. Duke of Buccleuch is a very fickle Grape—one that is sometimes stubborn when newly planted, and especially if the cultural conditions are not of the best. You can maintain ample atmospheric moisture without recourse to syringing the foliage or watering of the border daily by sprinkling water over the floor surfaces on sunny days with a fine-rosetted pot. If water is given to the border, sufficient should be applied to moisten the soil to

the depth of or below that occupied with roots. If you have examined the surface only, and found this amply moist, this does not imply that the same state exists at the depth of a foot. It may, with a daily sprinkling, be too moist on the surface, yet dry below, and if this exists, then to this you may, we think, rightly attribute your failure. It is nothing unusual when planting a new vine to find inequality of growth. We have had a perplexing experience in some such cases, while in others the progress is both even and satisfying. Newly-planted Vines ought not to be allowed to fruit, no matter how willing they may be to do so. The aspect of your house is that requiring early morning attention, opening the ventilators so that there is no undue rise of temperature. On sunny mornings air may be admitted as early as 6 o'clock, and closed again in time to husband some solar warmth for the Vines' benefit during the night. This may at the present time be possible from 3.30 to 4 p.m., earlier, of course, when there is no sun. The opening and closing of the ventilators must be governed entirely by the time of sunrise and sunset and the season of the year. The leaves you have sent clearly show an absence of vigour. Two-year-old plants certainly should produce stronger foliage, planted since the spring. If, however, there is an absence of suitable root moisture, Vines make but very poor progress, if they do not actually collapse. It would be impossible for us to say how often water would be needed, so much depending on local circumstances; but, in any case, we advise you to discontinue the daily watering, and give instead a soaking at less intervals, and note results of the change.]

STRAWBERRY PLANTS.

VERY often amateur growers complain that their first year's plants fail to fruit. That is generally due to their failure to secure the very earliest runners, and to get them well rooted early. Growers of Strawberries in pots for forcing always select their very earliest runners for such a purpose. They do more, for they put out into rows strong young plants the previous autumn, that in the spring are not allowed to bloom, and thus are induced to throw runners earlier than fruiting plants will. Small gardeners and amateurs may not be able to spare ground for such purpose, but in any case they should look well after the earliest runners made, and either layer them into small pots or into the soil where growing, just breaking it up first with a fork, or else cut off the strongest runners as they show roots, and dibble them out into a patch of ground that has been heavily manured, where they will grow strongly, and can be lifted and replanted where to grow and fruit in the following autumn. Wherever the runners are layered into pots or into the soil between the rows, the spaces between alternate rows only should be so used, so that space between each set is left free for fruit gathering, if not over, or for watering or giving such other attention as may be needed. In some soils Strawberry plants do not fruit well after the first year. In such cases it is best to make the ground fairly

rich with half-decayed manure, deeply dug in, and then to plant 12 inches apart each way. When young plants are strong and fruit well, they give in that way a surprising quantity of fine fruit. Even if so treated the first year, then, after fruiting, each second row be cut out, the plan pays well on any soil.

A. D.

SOME GOOD CHERRIES.

THE Cherry, running the Strawberry very close as to which shall ripen its fruit out-of-doors first, is a welcome addition to the dessert from early June onwards, though this season both will be late in ripening on account of the backward, cold, and unseasonable weather from early May up to the third week in June, when these lines were penned. I shall treat principally of trees grown under glass, but without fire-heat. All growers know that the Cherry of all fruit resents much fire-heat until the stoning is over. But in an unheated house, and with care exercised as to airing, watering, etc., it is seldom the crop fails. In my case, standard-trained trees with clean stems 6 feet

years with me, but the tree gummed badly, eventually going off, and has not been replaced. Black Eagle is a fine-flavoured Cherry of free growth. Early Rivers should be in every collection. With me this does not form so many spurs as could be wished, but the fruit finishes up grandly. Bigarreau Napoleon is a good late variety, the fruit large and excellent. Emperor Franeis, another late fine-flavoured fruit, comes up to a grand size, and, moreover, hangs well. St. Margaret's, too, follows in the train of late varieties, and valuable on that account, the fruit large and handsome, and the flavour all that can be desired in a Cherry when fully ripe. With the above-mentioned varieties a succession is ensured.

CULTURE.—The trees, of course, require attention during growth, syringing twice a day until the blossom expands, when discontinuing until the fruit is formed, after this the same practice is carried out until colouring of the fruit commences. If this is omitted the chances are red-spider, which soon works havoc with the Cherry, will attack the foliage before

the trees in any way until the fruit has stoned, or a large percentage will drop. Black aphid is the worst enemy the Cherry has, and the trees should be washed during the winter with soft-soap and sulphur, with a little Quassia extract or a small quantity of nicotine. Even then it is quite likely insects will appear on the foliage in early spring. I find half a pint of the Quassia extract put into 4 gallons of water will clear them of this enemy and do no harm to the tree, and if the shoots are very bad and curled, the points should be dipped in the solution and be well syringed next morning with clean water. Trees outside get similar treatment as regards washing, pruning, etc.

J. M. B.

NOTES AND REPLIES.

Shanking in Grapes.—I have charge of a vine, and the whole of the bunches are affected more or less as sample enclosed. The Vines are planted outside and their roots have probably gone beyond the Vine border into the lawn adjoining. Each year I give them a good sprinkling of Vine-manure and water it in, this being done after thinning. There has always been a difficulty in ripening them properly. What is the probable cause? Please.

[The Grapes sent are what is known as "shanked," and the fact of your Vine roots getting beyond the border into the lawn may at once explain the cause. The roots, getting into a cold subsoil, the young fibres perish and are unable to supply proper food for the development of the berries. If such is the case, your only safeguard is to lift the Vines from the border, and replant them.]

Pruning Gooseberries.—By way of following up the letter of "Close," the issue of GARDENING, June 28, p. 14, on the pruning of Gooseberry-bushes, allow me to give my methods. For a good many years now—more than a dozen at least—my Gooseberry-bushes have been pruned just about this time; this year, of course, somewhat later owing to the lateness of the season. The process adopted is as follows: All the young wood (of year's growth) coming up out of the base of the bush is cut out, leaving one or two buds on. In this way the fruit is not crowded; a check is given to exuberant growth, and, of course, light and air are more freely admitted. When the leafless bush is cut, two or three may be taken, but there is no pruning of the old-fashioned sort. A composition of lime, soap, and black soap is syringed on, and finally a black thread is warped and watered over the bushes. This latter is done if the district is infested with sparrows; unprotected the bushes would have a poor crop. Strange to say, there has been no appearance of the caterpillar, though plenty of black rust. In the dead season the bushes are treated with all available soap-suds and urine, with the result that the is always a crop.—FIFER.

—In answer to your correspondence regarding the pruning of Gooseberry trees I discovered last year from a friend who had been living in France, and who had watched the system of pruning Gooseberries there, where they have such abundant supplies, that their method is to prune off all the young shoots directly they make their appearance—i.e., in June, when they are also bearing fruit. The shoots are pruned back to within an eye, and also enough are pruned off to enable you, as the saying is, to put your head into the middle of the bush. I was glad to get corroboration of my information in last week's GARDENING from your correspondent "Close."—E. P. GIBBON.

Strawberries for forcing (Nov. No. 1).—Early in July will be found a good time to layer the earliest batch of plants for next year's supply, while for the late varieties towards the end of the month will be soon enough. I prefer 3-inch or 4-inch pots to layer in, filling these to within an inch of the top with loam chopped fairly fine, putting just a little fibrous stuff at the bottom for drainage. The soil should be made fairly firm with the fingers. The pots should be placed on a hand-barrow and conveyed to where the runners are, and an equal number of crooked pegs, 2½ inches in length, to fasten them in position, choosing the nearest the parent plant on the runner, and

Cherry Governor Wood growing in a pot at Gunnersbury House.

in length are trained to the back wall of two Peach ranges 50 feet and 95 feet in length respectively. The wires that carry the Peach-trees planted in front of the house are placed 16 inches from the roof, and the Cherries after reaching these wires are trained downwards to meet the Peach wood. Here they fruit abundantly, and begin to give ripe fruit the third week in May, and extend the supply until early in July. Black Tartarian, though classed as a late variety, is always the first to ripen with me. This is a grand fruit, swelling up to a great size and rich in flavour. Governor Wood, here figured, follows very closely, and is a good Cherry, very sweet, and, like its predecessor, a great bearer. The flesh soon decays if damp reaches it, and this is the evil to be avoided. When ripe Cherries are hanging give plenty of ventilation top and bottom whenever the weather will allow. Frogmore Bigarreau, a very nice fruit, of a paler amber colour than Governor Wood, bears well, and the fruit is richly flavoured. May Duke, a well known variety, requires little praise, the fruit of good size but more acid than the Governor. Even an early kind of good flavour, did well for some

the fruit has all been gathered. Neither must this washing be neglected after the crop is cleared, or like results follow. The main branches ought to be pretty well 2 feet apart when trained down the roof, or very little light or sun can reach the back wall. All shoots not required for extension or filling in should be pinched at the fourth leaf, and I have found that it matters little whether it is done before or after stoning, and all sub-laterals should be pinched throughout the season, when very little winter pruning will be necessary. The less cutting the Cherry gets the better for the tree. It is much better to root-prune in autumn if too robust wood is made. The Cherry, similar to all stone fruits, enjoys a fair percentage of lime or mortar-rubble in the compost of fibrous loam, and on no account should manure of any sort be given. Feeding is much better done from the surface in the shape of liquid-manure from the tank, diluted with clear water, or a sprinkling of some artificial manure when the trees are in active growth, and especially during the time the fruits are swelling. The greatest care is necessary with this fruit under glass, not to excite

pinching out the point beyond. If the foliage of the old plant is likely to shade the little plants, it will do no harm if a few of the leaves are pinched off. Afford the pots water twice a day when the weather is dry, and examine them occasionally and see that the little plants are taking root and not slipping away from under the peg. As soon as the roots can be seen at the bottom of the pot, cut the runners from the mother plant and stand in an open sunny position. There will be no need to shade or shade them in the least if the pots are filled with roots, but keep them well sprinkled with the syringe or a rose can, when they will scarcely feel the check. Repot into $\frac{5}{8}$ -inch pots before many days have elapsed, using a compost turfy loam and also about 1 quart of bone meal, soot, and wood-ashes respectively to 4 bushels, thoroughly mixing all together before using, and potting carefully with a potting stick, allowing nearly an inch for watering. Clean pots only should be used, and see that the little plants are fairly moist beforehand. After potting stand the plants on mesh bottom in the full sun. Give each one care to develop its foliage, so that sun and air can reach the crowns, without which thorough ripening is well nigh impossible. Examine the

PLANTS AND FLOWERS.

INDOOR PLANTS.

**A FINE GREENHOUSE RHODODEN-
DRON.**

THE Rhododendron Countess of Haddington, flowers of which we figure to-day, is the result of a cross between R. Dalhousie and R. ciliatum. The flowers on first opening are pale pink, but as they age become almost white. It differs materially from either of its parents, R. Dalhousie being straggling in growth, and R. ciliatum forming a low bush, while Countess of Haddington is of a bold, free growing character. One great advantage of this useful Rhododendron is that it may be flowered freely in small pots.

**PROPAGATING MALMAISON
CARNATIONS.**

PROPAGATION by layering is still the best course to pursue; it is the safest, as it is also the quickest. Two year old plants will make capital stock for propagation in this way, simply because the growths are longer, thus

shading being employed at such times as a matter of course. This latter should be removed as soon as the sun declines, and then air may be given, or if not windy the lights can be left off entirely until the following morning, so as to have the full benefit of the dew. Being layered in the fibre, but little watering will be needed. By adopting this plan the layers will be fit for potting in a month or five weeks' time, and this will allow a good interval for the young plants to become well established before winter sets in. This fact is all important in the future well-being of the plants. Late propagation, with a consequently late period before sufficient roots have been formed to carry the plants safely through the winter, means that a closer course of treatment has to be adopted. This is not at all congenial to the Malmaison or any other Carnation, for it must not be lost sight of that it is a hardy hardier plant and not a tender greenhouse one in any sense of the term. Anything approaching a close or stuffy atmosphere during the autumn and winter is decidedly injurious to the plants, as indeed it is at all times. It is of no use to attempt to make up in this way for time lost in layering. The

YEARLING PLANTS, if not wanted for propagation, should at once receive a shift into one size larger pots. In doing this do not hesitate to make use of about half and half good peat and turfy loam. If the loam be at all close and wanting in fibre, then employ more peat. Firm potting is essential, less watering being afterwards required. Slopping the plants frequently with water will cause them to go off at the base. Should any wireworm or other grub trouble the plants at any time, dust them over at once lightly with soot, leaving it to be watered in. This not only acts as a check, but as a preventive also, besides which it is also a manure in which Carnations delight. These plants should have all the light and air that can be given them, but be screened from easterly winds and from the intense heat of the sun during the day in very hot situations. This can be easily managed with ordinary shading. Plunging the pots in a dry time is a good course to pursue; it saves watering, too much of which is not beneficial at any time. During a wet period, on the other hand, the plants would be better not plunged, being merely stood upon a bed of coal ashes or upon bricks, so as to prevent worms from entering the pots. Just sufficient staking should be afforded after potting to prevent the shoots from breaking down; in doing this do not crowd the growths together, but rather draw them out. In the case of the young layers it will sometimes happen that an adventitious flower-spike will push up; rather than stop this encourage it, for one good flower upon a dwarf plant is a pretty sight during the winter months.

Flowers of Rhododendron Countess of Haddington. From a photograph by F. Mason-Good, Winchfield.

NOTES AND REPLIES.

Fuchsia buds failing to open.—I should be much obliged if you could tell me the reason of the enclosed buds of Fuchsia failing to open? The plant is looking very healthy, as do also the buds up to a certain stage, when they crack all round. The plant is in a box in a greenhouse, and has lately had some manure-water.—(MISS) HOPE K. BRACK.

[An excess of stimulants, with possibly rather too much water at the roots, is the reason of your Fuchsia behaving as you describe. If you discontinue the manure-water and give plenty of air your Fuchsia will in all probability soon recover.]

Spots on Pelargonium leaves.—I send some leaf of Zonia for your opinion as to cause and prevention of spots on the leaves. Last autumn these plants and others were overrun with small caterpillars, and as they are very choice sorts I dread another visitation.—CONSTANT READER.

[Judging by the leaves sent, we should say your Zonal Pelargoniums have had insufficient ventilation, for a free circulation of air in all stages is necessary to their well-doing. An excess of stimulants, too, will often lead to a disease (which may be compared to eczema) attacking the foliage, and this can be remedied by potting in good, sweet soil, withholding stimulants of all kinds till the pots are full of young, active roots. The caterpillars of last autumn have nothing to do with the diseased state of the leaves now, and should they put in an appearance later on, hand-picking is the only remedy. The larvae of the white Cabbage

plants twice daily, and water when necessary; dryness at the root must not be permitted at any time, and should red-spider attack them syringe with soapy water, with a little sulphur or lime mixed with it. All runners and weeds must be constantly removed and the plants turned round a few times during summer.—J. M. E.

Selecting Strawberry-runners.—

This is an important consideration. Those only should be employed that are stout and healthy, with a good round, plump bud in the centre; and they must be from fruit-bearing plants. When runners are taken at random from unfruitful plants, the progeny generally proves unfruitful also. It is of the utmost advantage, in order to obtain the runners quickly and to get them soon into their fruiting quarters, that they be layered into small pots about 4 inches or 5 inches in diameter, filled with rich loamy soil, and mixed with a little rotten dung. While they remain in the pots they must not be allowed to suffer from want of water. They will make rapid progress in this rich compost; as soon as they are fairly rooted they can be cut away from the parent plants, and as soon as convenient afterwards they should be finally planted out before the pots become matted with roots, and if the weather is at all dry well watered until they become established.

admitting of more effectual layering than in the case of yearling plants; besides which these latter will make fine plants for the earlier flowering next season. A good method to pursue is that of either planting out the old stools or plunging them in a frame. For instance, a frame that has been cleared of either early Potatoes or Carrots, and still is lying idle, will do well for the purpose. First level the soil and add a little fresh around the old ball if necessary as the planting is being done. Then give it a thorough good watering, and after that surface the soil all over with Cocoa fibre to a depth of about 3 inches, this also being watered. The layering should then take place in the usual way, the layers being pegged into the Cocoa-fibre. This material is a first-rate rooting medium, keeping a regular moisture around the layers, encouraging thereby a speedy root-growth.

After the layering is completed the fibre should be made firm and a sprinkling of silver-sand be added as a surfacing, with another watering as a finish. The lights should then be placed over them, but do not keep them closed so as to cause a too damp atmosphere. Such a condition will only tend to engender fungoid growth and cause green-fly. Close if needful during the daytime, more especially when an easterly wind is blowing or the sun very bright and warm. This latter advice may seem an anomaly, but it works out well,

lutterfly are very destructive to Pelargonium-leaves, as also are those of two or three nocturnal kinds of moths.]

Zonal Pelargoniums in winter.—The bright colours of these flowers are never more appreciated than during the dull autumn and winter. But to be successful one must grow the plants specially for that object. To let them flower all the summer and then expect them to give a display later is to court failure. The present is a good time to begin either by rooting cuttings or by obtaining young plants already rooted. Pot these into 3-inch pots, and stand them out-of-doors. In due time give them a shift into 5-inch or 6-inch pots, and use any ordinary potting soil. By ordinary potting soil I mean that free from mixtures of manures, which have a tendency to produce a gross growth. Pot firmly and allow the plants plenty of room to induce a short, stocky growth. Plenty of water is important during summer, removing also all bloom-buds. This latter may be done up to September, when the plants should be placed under glass. As the pots are by this time well filled with roots, feeding with stimulants is beneficial in producing fine trusses of bloom. Do not, however, feed the plants before. I would rather they have a starved appearance during the summer than large green, soft leaves. It may be well to mention the importance of standing the pots on a hard bottom so that worms may not get through the drainage and disturb the soil.—S.

Indian Azaleas.—Those that are now gone past or out of flower should at once have the few remaining blossoms (if any) and all the seed vessels picked off. The sooner this is done, the better will it be for the after growth to be secured and ripened in good time, for even in spite of the syringe thrips will increase rapidly at this season. The best remedy will be two fumigations at the least if this can be arranged for, otherwise a strong solution of soft soap and Tobacco juice should be used to syringe them with. More often than not this plant pest does the most harm to Azaleas after an exhaustive flowering period; it behoves us, therefore, to be on the watch against them. Young plants that are making a vigorous growth may be pinched with advantage; there is plenty of time for a second growth to form and then to set for flower. This plan is not adopted nearly enough; if it were, we should not see so many straggling plants as they get older; whilst in other respects, as the forming of a good base for a future specimen in equalising the growths it is a distinct advantage. Early forced plants will now have completed their growth under favourable conditions. Where this is the case, no time should be lost in hardening them off, so that in a few weeks in places where the plants can be stood outside they may be fully exposed.

ROSES.

BEFORE THE ROSES COME.

The first blaze of spring flowers is well over before the season of Roses and the summer garden flowers begins. The Wallflowers, Primroses, Tulips, and other bulbs during April and May make a fine show, helped as they are by the fruit blossom and the dwarf plants of the Arabis, Alyssum, and Aubrietia, in no way more effective than as broad edgings to borders, trimmed into form as soon as the flowering season is over, and left to run for the rest of the year. This gives a look of freedom and wildness to a garden, yet within bounds. But by June these things are over or quite past their best. It is between their period and that of the Roses at the end of June that so many gardens get dull. To fill this interval, the most effective plants—plants to produce an effect of colour generally rather than of beauty of the individual blossom alone—are Pyrethrum and Lupinus. For lasting, there is probably no outdoor flower to equal the Pyrethrum, if only its habit were more tidy. A heavy shower and a little wind, however, and the top-heavy flowers are all on the ground. The best way to manage the plant is to surround the clump with dwarf Pea-sticks, about 18 inches high, with perhaps a loose tie of raffia. If this is done while the plant is compact, just before the flower stems begin to

run up, the result is usually quite a natural-looking clump when in blossom. The Lupinus, when well grown, are stately plants, with fine foliage and handsome spikes of purple-blue or white, and they last over a long season. Like everything else, they will repay rich treatment. Rockets, single and double, too, are good. The mauve tinted white, the usual colours of the so-called double white, is very delicate and useful when well placed. An annual shift and rich treatment quite transform the character of this plant. The varieties of the German Iris, though lasting but a short time each, give a good succession, and if planted in a mixed clump give flowers over some time. Oriental Poppies undoubtedly give brilliant colour, but the space allowed them should be restricted if any consideration is given to appearances at other seasons. Pionies of the double crimson kind are usually failing by this season, but some of the other forms overlap the Rose season when they are hardly wanted. If a right selection is made, however, they are far too good to omit. They group conveniently with the shrubs, of which the Rhododendron and the Guelder Rose are, of course, invaluable. Other less showy but valuable plants for the same season are Perennial Carnulowers, of which the white is the best, the other colours looking rather weedy (these need supporting early), Campanula glomerata, with its fine violet flowers well out before the other Campanulas begin, and the Columbinas.

Among the dwarf trailing plants there are the white-flowered Mossy Saxifrage, beautiful either in or out of bloom; Cerastium, with its grey foliage and white flowers; Helianthemums—for dry soils—in various colours, of which the pale pink grows and flowers the most rampantly; and Woodruff, with its beautiful leafage and small, lily scented blossoms. All these dwarf plants trail about and look after themselves, so perhaps it is as well, as with Aralis, to put them in order once a year, as soon as the flowering season is over. There are also—too useful to be left out—the Forget-me-not and London Pride, though they almost belong to the earlier spring season, and the Tufted Pansies, which seem to belong equally to all seasons of the year. While many of these things are still at their best, the Delphiniums and the Pinks will be beginning to open, and from that time the season of Roses and all the flowers that make a summer is not many days distant.

R. B.

OWN-ROOT ROSES ECONOMICALLY PRODUCED.

ANY method of raising a stock of own-root Roses that ensures a good percentage of rooted cuttings of all varieties would naturally appeal to those who are interested in this branch of Rose culture. The method I recommend is simple in the extreme. It is merely a plan whereby advantage is taken of the summer's sun to obtain a quick callusing of the cuttings inserted. When a cutting is provided with healthy foliage and is practically in full growth it readily produces roots, and provided the proper condition of ripeness is observed there is no reason why every variety should not be produced as freely from a cutting as it may be by budding or grafting. Naturally, smaller plants are the outcome at first, but ere long the cutting will outstrip the budded plant. First, then, a frame should be placed in a sunny position. A very convenient size would be about 30 inches wide and the same in length. Several such frames should be placed in a line together, or may be in front of each other, provided the sun be not impeded. A depth of about 9 inches is a good one. This would allow of 3 inches of crocks, 2 inches of loam, sifted through $\frac{1}{2}$ -inch sieve, and then 3 inches of sharp silver-sand on top of the loam. Press the sand firmly, and give a good watering. It is now ready for the cuttings, the

selection of which is most important. The very best wood should be inserted, and none is better than the growths that produce fine blossoms. After the flower has developed about two days the wood is in a fit condition to be made into cuttings. I prefer two eyes for each cutting—that is, two leaf-stalks. The lower one is retained in its entirety, and the

upper one has the end leaflet pinched off. Cut the end of the cutting just below the eye with a sharp knife. The cuttings may now be inserted in the sand to a depth of 1 inch. They may be inserted thickly, but where frames are plentiful I would advise that the cuttings be planted an inch apart and 2 inches between the rows. When inserted the cuttings will appear like a thick layer of leaves. It is the proper treatment of the foliage that makes this method so successful. This consists in sprinkling with a fine rose can every hour from 9 a.m. to about 4 p.m., and is continued on each bright day for about ten days. On no account must the sand become dry, if possible avoid a soddened condition. The lights should be shaded with whitening, but to prevent it being washed off by rain some size and boiled oil should be added. At the end of ten or fourteen days, should the weather have been bright, young growths will appear from the top eyes. As the foliage shows signs of decay remove carefully. The frame should be frequently examined for such decayed leaves. The lights must be kept perfectly close until the new growths appear, then a chink of air may be given. By lifting one of the cuttings at the end of about four weeks, roots will probably be found some $\frac{1}{2}$ inch in length; if so, the cuttings are then ready for

putting off into 2-inch pots or frames, using a compost of sandy loam. One small crock will be ample in each pot. Other frames must be provided to take the potted up cuttings, and they should be brought as near the glass as possible. Keep close for a day or two, then give a little air, and shade from bright sun during first ten days. In a week or two the rooted cuttings will be ready for a shift into next size of pot. Keep all flowers pinched off the first year, and endeavor to harden the wood by exposure, as a soft growth always winters badly. By the fall, plants produced in July will be in 48-sized pots, and will be quite sturdy little specimens, but scarcely fitted to be planted out, so that it is necessary to hold them for another year in a well shaded frame or house. I may say all Roses will root readily after the manner described. It is new kinds are wanted for cuttings, dwarf pot-grown plants would be the best, and if the most is desired to be made of these single-eyed cuttings may be used. Ros.

NOTES AND REPLIES

Rose Beauty of Waltham.—Forty years ago this fine Hybrid Perpetual was introduced, and it remains to-day one of the most reliable of Roses. Its colour is a lovely bright light red, sometimes termed cherry red. The flowers are delightfully sweet, and of most perfect imbricated form. It is a free bloomer and also a good autumnal, and in vigour all that can be desired. The variety makes an excellent standard, the head spreading and not too dense. It is rather surprising few Roses have been raised from Beauty of Waltham, a this type of Rose could be increased with much advantage to our collection.—Ros.

New Rose Lady Roberts.—This charming variety has been seen recently in excellent form, and it is undoubtedly one of the finest additions of late years. It is said to be a seedling from the well-known Tea-scented Rose Anna Olivier. The new variety has a more dense buff shade of colour. In shape it has the full, as well as high-pointed, centre. It will be safe to say that this Rose will be much valued for exhibition, and it will also be among the easily-grown ones, as, like that of the parent, the growth is free.—H. S.

Effect of stock on the colour of Roses.—The other day I noted a striking instance of the difference the stock can make in the colour of the blooms in the case of *Maréchal Niel* Rose. In a greenhouse planted with this variety all except one plant were budded on the multiflora Rose as the stock. On marking how light in colour were the blooms, I came across one plant the flowers of which were some shades deeper in tint, and found that in this instance a Brier was the foster parent. As all of the trees are treated alike one can come to no other conclusion than that the stock makes the difference; although, in other respects, the multiflora stock seems in every way suitable for the *Maréchal Niel*.—S.

OUTDOOR PLANTS

WOOD ANEMONE (A. NEMOROSA).

In spring this native plant adorns our woods and also those of nearly all Europe and Asia, but it is so abundant in the British Isles that there is little need to plead for its culture. The form known as *A. n. major*, which we figure to-day, was collected in Ireland about seven years ago. It is a great improvement on the type, the flowers being quite twice the size, the plant also being a stronger grower, and also equally free flowering.

NOTES ON HARDY FLOWERS.

MORISIA HYPOCÆA.—This somewhat scarce alpine is a native of Sardinia. I am not acquainted with the conditions under which it is found growing in its native habitat, but I imagine that it will be found on hillsides, probably among dwarf herbage and in rather light stony soil. In any case it evidently requires good drainage, enjoys the full sun and a free circulation of air. With me it thrives very well on rockwork in gritty loam, but increases slowly. It is quite a diminutive plant with divided pale green foliage and tiny yellow flowers which are very freely produced. It is a bright, attractive little plant, and is

twenty good heads of bloom. A good soaking of water occasionally in great heat or drought will maintain vigorous health, and this little alpine, being so distinct and pretty, is well worth the extra labour that watering entails.

GENTIANA VERNA.—As growers of hardy flowers are aware, it is a matter of some difficulty to induce permanent vigour in this *Gentiana*. In the generality of gardens newly-imported plants do fairly well for a season or two, but they do not increase in size, and eventually dwindle away. This I believe to be in a great measure due to climatic influences, for it is no easy enough matter to give the right kind of soil, but the confined atmosphere of a garden is so different from that which this plant enjoys on the breezy hillsides, where it grows naturally, that unless artificial means are resorted to permanent vitality cannot be ensured. It is under the scorching sun of July and August that this little *Gentian* is apt to suffer so acutely, the slender wiry growths being apparently unable to resist the fierce heat and parching atmosphere that are apt to prevail at that time of year. They appear to become over-hardened and eventually shrivel, so that the energies of the plants are in a measure paralysed. Many of the current season's growths die away, the decorative worth of this lovely little alpine being permanently impaired. One way of

when fit to handle, and shade for a few days, keeping as cool as possible. Transfer them to 3-inch and 4-inch pots before they have a chance to get crowded, using a little fine mortar-rubble with the compost, which should be loam 2 bushels, leaf-soil $\frac{1}{2}$ of a bushel, passed through an inch sieve, and a peck of well-decayed cow-manure rubbed through a $\frac{1}{2}$ -inch sieve. Put firmly and stand in a frame, where they can remain until frost sets in, when remove to a greenhouse shelf. Shift into 5-inch and 6-inch pots as they become ready, and early in March move them into 8-inch or 10-inch pots, in which size they will flower, using the soil a bit rougher at each potting. Do not overwater during the dark days of winter, and only use a weak stimulant once a week when established in their last shift. The foliage is very sweet-scented when touched, which can soon be detected in a house. When in full beauty during July and August they are much admired, being so graceful in habit. I have used them to advantage in the flower garden, plunging the pot in the soil or on the turf. A sheltered place is necessary, or the fine pendulous shoots get broken, and thus spoil the appearance of the plant. To me the glasshouse seems the best place for the *Humea*, giving it a light, airy position. *H. elegans purpurea* and *H. e. alba* have purple and white flowers respectively. The plant is no good after going out of flower, a new stock being raised annually from seed.

J. M. R.

[Many years ago in a garden in Morayshire this plant was largely used as a centre piece for beds in the flower garden, and always did well. In some cases it was plunged pot and all, and in others it was planted out, but in both cases the results were equal. The only thing needful was to see that it was securely staked to prevent its being broken down. The soil in the garden referred to was a very light, sandy loam, which just suited it. — Ed.]

FUCHSIAS FOR OUTDOOR BLOOMING.

Most people who are fond of flowers have a special regard for Fuchsias. When one comes to consider Fuchsias in the light of outdoor-blooming plants, we are right when we say that to a great number of gardeners they are comparative strangers. Those even who grow them for indoor blooming do not to any very great extent "plant them out." It cannot be denied, however, that Fuchsias are as easily grown out-of-doors as the over-much patronised *Pelargonium* or the yellow *Calceolaria*, will bloom quite as abundantly, and, as at this time one may transfer them to the open, a consideration of their claims is asked. Anyone who has troubled about the British coast, as I have done, or who has visited the Isle of Man, must have been struck with Fuchsias grown under conditions utterly foreign to those who have been accustomed to view them only as "pot-plants." In those places they attain huge proportions—are even used as hedges, as they are in other parts of the south. *F. Ricurtoni* and *globosa* are examples of this, being grown in the mild climate out-of-doors the year round. Fuchsias for the flower garden with other small plants, for planting in window-boxes or baskets, or for growing in ornamental vases, may now be obtained for a modest sum, and in various colours, so as to present at blooming time a delightful contrast; moreover, one may rely on them flowering quite as freely as any other outdoor plant. Those who have not propagated any this spring may, as I have said, purchase young plants for a reasonable figure—in fact, at much less cost than *Pelargoniums*. I append a list of varieties that I have found most suitable for outdoor work, and would say that if they are purchased in pots it will be found that they bloom earlier if the pots are plunged in the borders:—

SINGLES.—Flocon de Neige, sepals bright crimson, corolla white, veined blue; Sedan, rosy red; President, sepals deep red, corolla salmon.

A fine form of the Wood Anemone (*Anemone nemorosa major*) in Messrs. Barr's nursery at Surbiton.

worthy of a place among choice rock plants. It does not appear to be one of those things that can be easily increased by division, but can probably be raised from seed, though I have not yet tried this method of increase.

SAXIFRAGA AFICILATA.—When in the enjoyment of favourable conditions this *Saxifraga* has a remarkably fresh and bright appearance all the season through. Another point in its favour is that it blooms very early in spring, when flowers in the open air are comparatively scarce. Like many members of the family, it suffers much in periods of parching hot weather, and it is therefore wise to place it in the rock-garden, making the soil very firm round the root. In the case of this *Saxifraga* I find it very helpful to embed small stones or, better still, pieces of chalk round the roots, and in the case of established plants a top-dressing of loam and leaf-mould, applied in autumn and worked in among the young growths, will help to maintain vigour. In the north of England and in districts where the rainfall is above the average, this species does much better than where it is liable to be subjected to periods of severe drought, which in a great measure destroy the rich verdure that characterises this *Saxifraga* in its normal condition, and thus cause it to miss flowering. It is very provoking to see specimens a foot or more across with only two or three small flower trusses, when there should be from twelve to

neutralising the effects of very hot sun is to annually top-dress about the beginning of July, using fine material composed of loam and leaf-soil, with a sprinkling of lime or powdered chalk, and working it well in among the young growths. This protects them against the desiccating effects of the hot summer sun, and induces the formation of new roots from the crown. If an occasional soaking of water can be given, the young growths will remain fresh and plump, and will form healthy flower buds. J. C., *Ryffest.*

HUMEA ELRGANS.

This is an effective plant when well grown, and to do it justice ten to twelve months must be given before plants of much value can be had. Towards the end of June is a suitable time for sowing, first preparing a 6-inch pot or a pan by filling nearly to the top with a mixture of loam and leaf-soil put through a fine-meshed sieve, adding just a little sand to keep the compost sweet. Water the soil before sowing, letting it drain for a couple of hours, then scatter the seed quite evenly over the surface, and but lightly cover, as the seed is very small. Place a piece of glass over the top of the pan or pot, and stand in a cool, shady place until the seedlings appear, when insure to light and air, giving water with judgment, as they so soon get wrong. Prick them into similar pans

corolla orange-scarlet; Countess of Aberdeen, sepals and corolla pure white; Excelsior, sepals carmine and reflexed, corolla lilac-mauve; Earl of Beaconsfield, sepals and corolla orange-red; John Gibbons, tube and sepals dark crimson, corolla dark blue.

DOUBLES.—Phenomenal, sepals red, corolla blue, enormous flowers; Frau Emma Topfer, sepals red, reflexed, corolla rosy-blush; Molesworth, tube and sepals rich rose, corolla white; President F. Guntbier, sepals red, corolla violet; Fortuna, sepals crimson-red, corolla white; Beauty of Exeter, salmon-scarlet self.

For ornamental vases, where plants and flowers of a hanging habit are needed, few better subjects could be employed than Fuchsias. W. F. D.

NOTES AND REPLIES.

Torch Lilies (Tritomas).—T. Uvaria is the best known probably of the genus, and when once established gives little trouble. Tritomas need a deep soil and manured from time to time, and are best adapted for well-drained borders, as on cold, heavy soils with a winter like the last they not infrequently die off. Having regard to this, it is wise to afford the roots some little protection with light, warm material, such as straw litter, leaves, or Bracken. —LEAMINGST.

Oriental Poppies.—I think more would grow the Oriental Poppies if they knew how comparatively easy they are to grow and how hardy they are. As with other varieties of Poppies, seed of the Oriental Poppy is very small, and should, therefore, be sown in boxes in a cold frame now for next year's display, and planted out later where they are wanted. They need little attention when once established, and may be counted upon to bloom well every year. Mine have been in their present quarters several seasons, and never fail to flower freely. —LEAMINGST.

Clematis Beauty of Worcester falling.—This plant, three years old now, has only flowered once, and has had but the one flower. Last year the whole plant withered in one night. This was thought to be due to great heat or wireworm. The plant was moved to a more sheltered situation, and has appeared again in healthy state, only to wither. What is the cause? —E. V. R.

{Very probably your plant was grafted, in which case the Clematis often goes off in the way you say. This is by some attributed to disease, doubtless brought about by the pernicious forcing adopted in its infancy. We should advise you to cut the plant down, and if the roots are right it may probably break again.}

Spanish Irises.—There are few Irises so easy to cultivate, certainly none that take up so little room, as the Spanish, and whose delicate and beautiful blossoms are with us now. Particularly adapted for table decoration, in consequence of their graceful appearance, they should be grown by all who value cut flowers, and the bulbs being inexpensive one may plant them liberally and confidently anticipate a bountiful supply of blooms. If the bulbs are planted in groups in the borders, or rather thinly in a bed by themselves, one may sow between Mignonette, which comes in nice for succession. One rather pretty arrangement is to plant alternately with Iceland Poppies, another equally desirable blossom for vases. —DERBY.

Staking Dahlias.—When old undivided roots are replanted, as is sometimes done, it matters little when stout stakes are affixed to the plants; but in the case of hard divided roots or of those which have been raised from cuttings (the common method of propagation), it is wise to get the stakes fixed soon after the planting is done, as then in driving the stake into the soil no harm is done to the fleshy roots. Some growers, after the holes for the reception of the plants have been prepared, drive a stake into the centre of each one at once, and thus prevent the possibility of harm being done at all. But it is not always convenient to adopt that course. In pointing the stakes it is well to have no sharp angles or edge, but to trim the points round and smooth, also have them well driven home, and thus render them secure. The tying up of the main stem and branches should be done rather loosely, as the wood of Dahlias necessarily swells very much in the autumn. —GARDENING ILLUSTRATED BY

Lawn weeds.—We have recently seen a lawn greatly infested with Plantain and other coarse weeds, on which efforts to kill these pests had been made by dropping lawn-sand, as it is called, on to them. The effect was objectionable, as myriads of them looked like dirty patches, and it was but too evident that whilst some of the leafage was killed, the root, stem, and lower leaves were still alive. Had the time spent in thus dressing each individual weed been utilised in cutting each one out, the result would have been satisfactory. Weed extracting of this nature can be done constantly, except when the turf is hard frozen, but when the process is persistently followed up the result is that in time every coarse weed disappears. If in heat and drought deep-rooting weeds hold on whilst the Grass dies, in wet seasons such as the present they make very coarse growth. But if they are extracted now the Grass will soon cover the bare places thus created, and in a short time they are obliterated. —A. D.

Forget-me-nots.—Though devoid of scent there is, nevertheless, a charm about these spring flowers. Forget-me-nots last fresh for a considerable time in cool dwelling rooms. *Myosotis dissitiflora* is a general favourite because of its hardiness, early flowering, and depth of colour. This, too, is good for pots, and may be forwarded by some weeks in a greenhouse temperature. A striking but later variety is *M. alpestris Victoria*. This has a denser panicle of flower, dwarfer growth, and, if anything, is more conspicuous in a mass than the first named. The past winter has proved the hardiness of many subjects. This kind survived the ordeal, and in my case out-distanced *M. dissitiflora* in point of hardiness. Another and miniature kind is *M. alpestris gracilis*. This, too, was equally hardy, and in its early season resembles very much in colour and compactness the summer *Lobelia*. As an edging to spring beds or grouped alone it has a pleasing effect, and is sure to arrest attention. —W.

Single Cactus Dahlias.—Where it is possible, these should be planted on a border which has a raised terrace at the back. The terrace saves the plants from many a gust of wind, and, better still, it shows the flowers off to advantage, especially if the plants be a mixed lot. I prefer raising plants every year from seed, getting it from a reliable firm. The diversity of colour and the robustness of the plants commend this method to all. The soil for these Dahlias need not be rich, nor should it be too poor. Good garden soil which has been manured the previous year suits them admirably. They will require to be firmly tied to the stake, as, being of a branching habit, they soon get broken if attention is not given. A little liquid-manure should be given when the buds are well set, but care should be taken not to overdo it, as gross growth will be the result, and the blooming will be retarded. The same result happens when too much water is given them if the season is dry. The cut blooms are charming when arranged loosely in a vase or jar with a little of their own foliage. —D. G. McI., *Bridge of Weir, N. B.*

Lobelias from seeds and cuttings.—Lobelias are much in request as edgings to borders, etc., during the summer. In the early spring, if one could peep into most greenhouses one would find boxes of young stuff as evidence of this. It is often a point for discussion amongst gardeners as to which is really the best mode of raising plants—whether it is worth the trouble to save old ones during the winter, or to sow seed in the spring. Personally, I think there is something to be said in favour of both methods. Very often those who dig up old plants in October find that after keeping them in the house for a month or so they damp off. Thus the system is condemned and seed has to be sown. Is it wise to propagate from old spent-out plants? I think not. In my opinion it is the best to have prepared in August boxes of sandy loam into which cuttings can be dibbled; these will root readily at that time, and by October have developed into bushy little plants, which will stand the winter in the greenhouse, not damp off so readily as plants lifted from the borders, and by February will be full of young shoots ready for the propagating-pit. Where this cannot be carried

out, then I would sow seed in heat in February. One may not always rely on seed, as it not infrequently happens that some of the plants when they come to bloom are lighter in colour than others. This is got over where a stock of autumn-raised cuttings is kept, from which it is comparatively easy to raise a large number of plants for the borders, and I always find that plants raised from cuttings flower the earlier. —WOODBASTWICK.

Polyanthuses.—Although these are looked upon as hardy, severe winters sometimes make havoc amongst them. Where, however, they can be planted at the foot of a warm wall, the little protection thus afforded will often tide them over the severest winter. Some of mine in beds that lay under the snow for a long time this winter were found to have rotted away, but those under the wall are at the time of writing showing for bloom. Now is the best time to sow seed, and plants raised will blossom next year. Polyanthus seed is very slow in germinating, and one is liable to get impatient about it, but it invariably comes. Seed should be placed in boxes in a cold-frame, and the young plants got into the borders in the autumn. —LEAMINGST.

Plants for stone elder mill.—I have just moved into a sunny position an old stone elder mill, about 3 feet or 9 feet in diameter, with a solid block of stone in the middle and a large trough round it, about 15 inches deep. I am anxious to cover it with plants and creepers. It is in two pieces, and by not quite joining the two halves and sloping the earth towards the crack, it would be drained. Will you kindly advise me as to the plants I think could grow in the trough? It is not possible to plant anything in the ground near the elder mill, as bed of marl comes to the surface there. Would Rock Rose, alpine plants, alpine Roses, *Daphne*, *Cotoneaster*, and *Clematis* be likely to thrive? The spot is sheltered by walls on three sides and open to the west. —MARJORIE E. CURIE.

{There are many things that should not only do quite well, but prove suitable and picturesque also. If you could place other rough stones on the central block with a view to making a cone-like centre of an informal character, then we would suggest the planting of *Cotoneaster microphylla* or *C. Laelandi*, in such a way that these would mass together in the centre portion, the object of the added stones being merely to support the plants, instead of these producing quite a flat area. Some rough and old stones would be best, to be in keeping with the millstone. Oryon may plant such a *Clematis* as *C. montana*, *C. Viticella*, or *C. Jackmani*, the older kinds preferably. In the trough, that should be nearly filled with good soil, you could plant such things as alpine *Phloxes*, or any of the dwarf *Phlox setacea* varieties, with *Ajugas*, *Veronica prostrata*, *Vinca*, various *Aubrietias*, and such-like, to hang over the sides, together with *Campanula garganica*, *C. muralis*, and *C. pusilla* in variety. All these are dwarf-growing and trailing, or nearly so. Of other things suitable for centre of the trough, we may mention *Columbines*, *Rosa alpina*, and *R. a. pyrenaica*, or, in place of either of these, the copper and yellow Austrian *Briers* would succeed well. These, with *Lychnis Viscaria* fl. pl., *L. Haageana*, *Arnebia echinoides*, *Fritillarias*, or Crown Imperials, *Statice latifolia*, *Physalis* *Franchetti*, *Plumbago* *Larpenae*, would furnish it well with old-fashioned flowers for the most part, and give an interesting variety also.}

Misleading names.—At the flower show at Holland House the other day we saw what we see so often done at shows of late—i.e., many *Anemones* shown under the name of St. Brigid's *Anemone*, which is misleading and wrong as a name for a class. They are simply well-grown seedlings of the plant grown in English gardens for ages under the name of Poppy *Anemone*, or Crown *Anemone* (*A. coronaria*). We have no objection to anyone calling any one variety St. Brigid or any name he fancies, but to give a new general name to a class of well-known and very old flowers should not be done or encouraged. It is wrong, because it leads people to fancy that they are dealing with a new group of flowers, and adds to the already too numerous names by which we are confused. The trick succeeds so well in sales that it will probably be followed in other instances. Real novelties are different and deserve distinguishing names. Pedigree *Roses* was another class of misleading names, as they were in no sense more pedigree than any other seedling

THE GARDEN CLEMATIS.

ONE of the most useful and beautiful climbers is the Clematis, and few pictures are more familiar in gardens than the violet-purple coloured *C. Jackmani* that wreathes many a pillar, post, and rustic doorway with its free growth and countless flowers. As there are several distinct sections of the Clematis, it will be well to refer to them under their separate headings and briefly touch upon their cultivation. There is nothing troublesome in growing this climber, and the freedom of Jackman's Clematis shows the vigour and hardiness of the plant even when associated with sturdier things that seem determined to choke it. Some of the prettiest effects in gardens are the result of

lessly will simply result in pruning away the next season's flowers. This is sometimes done, and the plants complained of as shy flowering. A different course may be followed, however, with the Jackmani and Viticella types, which usually bear large, variously coloured flowers in summer and autumn on the young shoots, which should be therefore encouraged. Cut back the plants when their beauty is destroyed by frost to within a few inches of the soil, and give a mulching of manure. This is a short review of the culture of plants which are of free growth, hardy, and may be grown in various positions in the garden, while they give a profusion of bloom of various shapes and colour over a long season. The Jackmani type is the most common, except such a variety as *montana*, and besides

(white, tinged with cream) are also popular kinds, while such kinds as *Fair Rosamond*, *Miss Crawshaw* (here figured), *Lord Londesborough*, *Mrs. G. Jackman*, and *Miss Bateman* are excellent. Two other types remain, and these are *florida* and *lanuginosa*. Of the former, one of the finest is *Duchess of Edinburgh*, a pure white, double flower, sweetly scented, and very chaste when the plant is in full bloom. Another full and bold flower is *Countess of Lovelace*, while *Fortunei*, *John Gould Veitch*, and *Lucie Lemoine* are worth having. The *lanuginosa* class is larger, and embraces some very choice flowers, as *alba magna* (white), and the sky-blue coloured *Blue Gem*, *Henri* (creamy-white), *lanuginosa candida* (grey-white), *Gem* (lavender-blue), *Louis Van Houtte* (bluish-purple), *Olto Froebel* (one of the very large-flowered kinds, with blooms of a greenish-white tone), *W. Kennett* (lavender), *Princess of Wales* (bluish-mauve), and *purpurea elegans* (violet-purple).

These are a selection of a few of the best in their several sections, and in disposing them in gardens I may remark that the common way of nailing the plants to a wall is not the most happy, if we want the full characteristic grace and elegance of the flowering shoots. We do not care for the varieties that bear very large, saucer-shaped blooms, but rather for those of smaller size, which are more in keeping with the character of the group. The first remains that, familiar as the Clematis is, it is principally the smaller class of gardens in which they are planted, not the large places that have many odd and bare corners, walls, pillars, and posts that such charming things would wreath in growth and flower. The Clematis, in one or other of its many varieties, would fill the gaps, and give pleasure by the boldness, freedom, and beauty of the variously-coloured flowers, which range from white to the deepest purple.

FERNS.

TREATMENT OF FERNS DURING THE SUMMER.

FERNS, as a rule, are well attended to during the early spring months as regards potting, watering, shading, etc., but the same amount of care is not always bestowed upon them throughout the summer. As the season advances and the earlier growths mature the plants must not be neglected; they rather require looking after even more closely than in the spring.

INSECTS, which in the early part of the year were not plentiful or that had been cleared off either by the removal of the old fronds or by other methods, will now be again giving trouble if not well looked after. Both thrip and scale will cause considerable annoyance if they escape notice until the plants are seriously affected with them. This work, on the other hand, if taken in time is easily kept under; not so, however, when in the ascendancy, the plants being frequently disfigured for the rest of the season, more particularly in the case of thrip. Where the oldest fronds are badly affected it is better by far to remove them at once, provided they can be spared; the cleaning in many cases of such is a waste of time. The under fronds will be those most likely to be attacked; these in most cases can be spared if seen to in time so as not to cause the removal of too large a quantity. For the thrips nothing surpasses a good syringing or dipping in a weak solution of soft soap and Tobacco water, or where possible fumigating two or three times. Either remedy should be given in time so as to avoid repeated applications.

OVERCROWDING the plants is another mistake. This may possibly result from a previous luxuriant growth or by reason of having a larger stock than can be conveniently accommodated. It is well to have the plants thriving as it is to have them in good numbers, but when it comes to crowding the plants there are drawbacks that point to plants of less size or fewer in numbers. A deal may be done towards remedying this by shifting the plants to other quarters. These Ferns, for instance, which are wintered and grown in the spring in the open and that are known to be tolerably hardy can be kept for some months in a cooler and drier atmosphere with advantage both to

Clematis Miss Crawshaw. From a photograph by G. A. Champion.

growing this climber with Ivy, the rich green foliage bringing out the intense depth of the flowers. A light loamy soil is best for all the Clematises, and the growth is stronger and the display of bloom more profuse if a little lime is mixed with the loam. There is one thing to guard against—i.e., an over-saturated soil, and it is thus necessary to have a well drained material to promote vigour, which must be maintained by a good dressing every year of manure, or on a heavy soil leaf-mould.

PRUNING.—In the case of the types represented by the lovely *C. montana*, that sheets many a garden wall and cottage with white flowers in spring, *florida*, *patens*, and *lanuginosa*, cut out in February or March weak or overcrowding growth, laying in the strong and well-timbered one-year-old shoots. To cut care

the type that everyone knows we have a white form, its early flowers, however, appearing pale mauve in colour, but those subsequently produced are white, as indicated by the name; *Alexandra*, reddish-violet, the well-known *velutina purpurea*, *tunbridgensis*, mauve-blue; *rubella*, claret; *Gipsy Queen*, very deep purple; and *ingulfica*, purple barred with red, are the finest, whilst those in the *Viticella* group which should have recognition are *Thomas Moore*, violet with white stamens; *Viticella rubro-grandiflora*, claret-red; *Lady Bovill*, blue-grey; and *Mrs. James Bateman*, lavender. One of the great classes is the "patens," those varieties that bear large flowers in the spring of various shades. *Standishii* (blue-purple) is one of the most charming. The *Queen* (lavender) and *Veitchii*

themselves and others remaining in warmth. Again, other Ferns grown as a rule in a temperate house can be accommodated in a cool-house and others in frames and pits even; anywhere, in fact, that is at all suitable rather than allow overcrowding, with its attendant evils, to ensue. In this removal to other houses there are many advantages, the plants becoming hardier and more enduring in growth, whilst additional material is also afforded for the conservatory or show house when flowering subjects are neither so much required nor any too plentiful.

WATERING, too, calls for increased attention now, the pots being (or, at least, should be) well filled with roots. Ferns at any time do not look well if in pots or pans of excessive size, nor are they any the better for overpotting. It is far better to have the plants well rooted, so that they will take a liberal supply of water without that fear of softening the soil that is ultimately the case when overpotted. There is a wide difference in Ferns as to the quantity of water they will absorb, but in no case is a dry course of treatment now to be recommended. Gymnogrammas with healthy roots take a large supply. When these Ferns are neglected and the fronds begin to curl, it is a difficult matter to bring them round. Nephrolepis, too, take a liberal quantity. These Ferns do not show symptoms of distress so soon as many when in reality they are suffering, the result being seen a few weeks afterwards in the pinnae turning yellow and dropping off. In no case is it advisable to let Ferns droop before they are watered; some may come round again and not feel the effects, but the majority do so. The conditions of the house or fernery as to atmospheric moisture have an immediate bearing upon the plants in this respect. In a dry, airy house the plants will require almost twice the amount of water at the roots that others of the same kind would do in a moist atmosphere, yet if well attended to the former would thrive as well. This results from the roots in the former instance having more work to do, less absorption taking place through the fronds than under more congenial conditions. Where Ferns are found to dry up rapidly, it is a good plan to stand the pots in pans of water. Maiden-hair Ferns, for instance, which are well rooted may be safely stood in saucers filled with water. Where it is not desirable to actually allow the pots to stand in water, it is a good plan to let them stand over it and upon bricks or rough drainage. D.

TREES AND SHRUBS.

MAGNOLIAS.

BEAUTIFUL as are many of the flowering trees that adorn our gardens and pleasure grounds, there are none that can rival for size of blossom or for effective display some of the Magnolias. No more exquisite sight can be imagined than a fine tree of the Yulan (*Magnolia conspicua*), some 30 feet in height, in full bloom against a background of flixes. The blossoms are produced early in April while the branches are still bare of leaves, and, every spray being covered with the pure white flowers, the tree looks like a suspended snowdrift, thrown into high relief by its dark setting. Another spring-blooming deciduous Japanese Magnolia is *M. obovata*, of rather dwarf habit, bearing flowers white within and purple on the outside. *M. o. discolor*, or purpurea, is a form of the last, with larger flowers of deeper tint. *M. Soulangeana*, almost as well known as *M. conspicua*, is a chance hybrid between that species and *M. obovata*, and bears white flowers with a pink flush on the outer side of the petals. *M. Lenei*, with flowers of a deeper hue than those of *M. Soulangeana*, is a hybrid between *M. conspicua* and *M. purpurea*. It has the decided advantage of usually bearing a second crop of blossoms in the autumn. *M. Alexandrina*, with very similar flowers to the last-named, is the earliest bloomer of the Japanese hybrids, of which *M. Osaka* has deep purple-maroon flowers. *M. stellata* or *Halleana* is a charming shrub, flowering in March before the leaves appear. It bears small starry flowers about 3 inches in diameter, which are pure white when they expand, but afterwards assume a pinkish tinge. *M. Watsoni*, a later introduction, is very beautiful, but, unfortunately,

are cup-shaped, 6 inches in diameter, pure white in colour, with deep rose-coloured stamens. *M. parviflora* is very similar, but has smaller flowers; both flower in May and June. *M. grandiflora* is, perhaps, the best-known Magnolia in this country, and is generally trained against house walls. In the south-west, however, there are many standard specimens, some of which have attained a large size. The Exmouth variety bears the finest flowers. In the neighbourhood of Torquay there is a standard tree of this Magnolia about 25 feet in height and 30 feet in diameter, which bears hundreds of its great, ivory-white, scented chalcids in the season. Generally commencing to bloom towards the middle or end of June, it flowers continuously until October or November. The individual flowers are often fully 8 inches in diameter, and the petals are of greater substance than those of any other Magnolia. *M. macrophylla* is a splendid tree, but is little known in this country. There is, however, a fine specimen, 40 feet in height, at Claremont. It is deciduous, and bears immense white flowers nearly a foot in diameter, with its handsome leaves, bright

pointed "Baron Ed. de Rothschild." It was a Rhododendron as we consider them, not at all resembling an Azalea, a large bush, and very striking amongst the usual whites and pinks. L. R.

Cutting down Laurels, etc.—I have in a grove adjoining the house a good many old Laurel-trees and some other evergreens, which have long, bare, and twisted stems. I have been advised by a visitor that to cut these down, close to or near the ground, would make the most showy young growth, which would greatly improve the look of the grove. The questions are: 1st, Is this most probable? 2nd, Should the Laurels be cut close to the ground, or at about what height? 3rd, At what time of the year should the cutting take place? Information is also asked as to the most advisable time of year to plant evergreens from enclosed garden ground into grove. In this case I have in a garden Escallonia planted from cuttings, and now five or six years old. At what time would it be best to remove these into the plantation, which it is proposed to ornament with them?—K. G. H.

(Old Laurels will, as a rule, break out freely if cut back hard, not close to the ground, but leave about 18 inches of the old stumps, so as to be from these (not from the roots) that the new shoots are pushed forth. The best time of the year to carry out this operation is in the month of April, as they have then a long growing season before them. The Escallonias may be

Magnolia buds.

green above and silvery beneath, are from 15 inches to 2 feet in length and 6 inches in breadth. *M. Fraseri* is another deciduous species, bearing pale yellow, aromatic-scented flowers, 6 inches in diameter. *M. Umbelliflora*, from the Sikkim Himalayas, bears rosy-crimson flowers, 8 inches in diameter. It is only hardy in the warmest districts in the south-west. Other species are *M. acuminata*, *M. cordata*, *M. glauca*, *M. hypoleuca*, *M. Kuhnii*, and *M. tripetala*.

The blossoms of Magnolias are without peers for indoor decoration. *M. conspicua* and its hybrids, *M. Soulangeana*, *M. Lenei*, and *M. Alexandrina*, are equally acceptable in the house, as are the massive blooms of *M. grandiflora*, the white cups of *M. Watsoni*, the pale yellow flowers of *M. Fraseri*, and the giant blossoms of *M. macrophylla*. S. W. F.

NOTES AND REPLIES.

A yellow Rhododendron.—I see in *GARDENING ILLUSTRATED*, of June 21st, "E. A. R. W." asks for the name of a yellow Rhododendron. At the flower show in Paris, May 21st and following days, there was a beautiful orange Rhododendron shown by Moser, of Versailles. He called it Azalea

removed at the end of October or in November, but as they have stood five or six years from the cuttings without being shifted it is very probable some of them will die. In nurseries where plants are grown for sale they are removed generally every year—or, at all events, every two years—in order to keep the roots dense and compact. Take care to plant firmly, and should the weather be at all dry give a good watering, as this tends to settle everything in its place.]

Magnolia falling.—I have taken in your valuable paper, *GARDENING ILLUSTRATED*, for some years, and have read with interest many of your answers to enquiries respecting the culture and growth of plants and the cause of failure, and I shall feel very grateful if you will give me your opinion as to the decay of the enclosed specimen of a Magnolia, which up to the spring of this year has grown beautifully and been perfectly healthy. It was planted on the southern side of my house about eight years since in a clay subsoil. It has grown nearly 12 feet high and broad in proportion. The year before last there were two or three very fair blossoms on it; last year there were several very fine, large, healthy ones. The plant was through the winter well, and there were blossoms beginning in April last; the end of the month the leaves began to die and turn brown in the centre of the tree. After a short time my gardener cut all the dead part out, leaving the other healthy and well; but very shortly one led after another became brown, and the whole tree went. I had the tree left till this morning, hoping that it would break out again, but it is so thoroughly dead and is so unproductive that I have now had it dug up. The roots

the gardener may, are healthy, but all the stems coming from them are dying or dead. You will, I hope, forgive my troubling you with this long letter, and if you can tell me what you think the cause can be I shall be so much obliged to you. On the other part of the wall I have a white Banksian Rose, planted between four or five years since. It has grown immensely, being between 30 feet and 40 feet high; the foliage is thick and beautiful. Last year it bore two or three very small flowers; this year there is not a sign of a bud. It has been properly trained, but not pruned.—ELIZA M. BARTON.

[No doubt the roots of the Magnolia had gone down into the cold clay subsoil and become waterlogged. One thing the Magnolia must have is good drainage, and this very probably is what your plant feels the loss of in such a soil as you have. The Rose evidently wants the exhausted wood thinned out, the growth being too thick for the wood to ripen properly, hence the failure to bloom.]

GARDEN PESTS AND FRIENDS.

Madonna Lilies diseased.—My Madonna Lilies are more diseased this year than I ever saw them; so are many of the other Lilies. Will you tell me what to do with the bulbs and when? The plants have been syringed with an insecticide several times. What causes the disease? Hollyhock disease, too, is dreadful this year.—YVO VILK.

[Lifting the bulbs and shaking them up in a bag of sulphur has sometimes proved a remedy, while, in other cases, lifting and baking in the sun, afterwards replanting in fresh quarters, have also proved efficacious. It is, however, very difficult to suggest any remedy for this pest, which is really a fungus.]

Insects on Apple-trees (J. Baster).—The insect infesting your Apple-tree is the Apple aphid (Aphis mali). During the winter—that is, any time between the fall of the leaf and the first signs of the buds opening in the spring—the trees should be sprayed with a caustic alkali wash, and in the spring, as soon as any signs of the aphid can be seen, the leaves should be sprayed with a solution of paraffin emulsion. These insects breed with such astonishing rapidity that it is very essential to kill the first that appear. Any shoots that are badly attacked should be cut off and burnt at once. This insect, though nearly related to the American blight, is quite a distinct species, and its habits are very different.—G. S. S.

Snake millipedes.—I enclose two specimens of a small garden pest, which is extremely common this year. It abounds both in the greenhouse and outside, and has destroyed many Scarlet Runner seedlings by eating through the stem as soon as they appear. I find them easily trapped in pieces of Potato, but shall be glad to hear of another cure, and also the name of the pest.—CARR.

[The two specimens of a small garden pest which you find very common this year are snake millipedes, commonly known as flattened snake millipede or galle worm; their scientific name is Polydesmus complanatus. They are most destructive pests, and will feed on the roots of most plants, preferring those that are somewhat succulent. I know of no better way of destroying these millipedes than trapping them with slices of Potato as you have done, but you might use Turnips, Mangold, or Carrots in the same manner. After an infested crop the ground should be followed and well dressed with gas-lime.—G. S. S.]

Plant bugs.—I enclose an insect resembling both a beetle and butterfly in certain particulars, and shall be glad to learn its name and a little of its life history.—CLAR.

[The insect that you suggest resembles in some particulars both a butterfly and a beetle is one of the "plant-bugs," and belongs to the family Pentatomidae. The plant-bugs can hardly be said to be "garden pests," as it is seldom that they occur in sufficient numbers to be the cause of any appreciable injury to plants, at the same time they are occasionally. They mostly feed on the juices of plants, which they obtain by piercing the leaves or young shoots of plants with the probosces or beaks with which their mouths are furnished. Several species feed on other insects, and some, including members of the family to which the specimen you sent belongs, suck the juices of either plants or caterpillars, apparently without showing much preference for an animal or vegetable diet. If these insects are very numerous on your plants and you wish to destroy them, I should shake the plants over an open umbrella or a butterfly net, and then syringe or spray the plants with a solution of

paraffin emulsion or some similar insecticide containing soft-soap, of which there are several kinds in the market, and though they are more expensive to use than paraffin emulsion, the trouble of making the emulsion is saved, and if only a small quantity is wanted the difference in price is hardly worth considering.—G. S. S.]

VEGETABLES.

SAVING BROCCOLI SEEDS.

MANY are inclined, when among a bed of Broccoli there happens to be an unusually good head, to allow this to go to seed with the prospect of getting a good stock for future sowing. The object is a very good one when carefully carried out. An instance occurs to my mind of a gardener who once did this, having among a breadth of Late Queen and Model some uncommonly fine Broccolis. In his effort to save his own seeds he neglected to protect the flowering head from the bees which were numerous in the neighbourhood. The result was a disappointment, for the

trouble of enclosing individual plants as a precaution is not taken, and yet they do not suffer the disappointment already noted. In these cases probably the district is not frequented by bees. At the same time, apart from bees, there is a risk of growing seed when the sowing is of so doubtful a nature.

W. S.

NOTES AND REPLIES.

Handlights in the garden.—I often think when looking round gardens that we overlook the usefulness of some of the simple appliances in our haste to try modern innovations. Since the introduction of cheap moveable frames, handlights appear to have lost favour. This is to be regretted, seeing that these can often be used where frames cannot. I prefer handlights for protecting vegetables, as they are far more convenient, seeing they can be placed over anything that is not too tall, and they will bring it on rapidly in spring. All through last winter and spring I have been more than ever impressed with their value for protecting Parsley. I always

Magnolia Fraseri in the Azalea Garden at Kew. (See page 258.)

following year after the sowing of the home-saved seeds his Broccoli, which was promising enough up to a certain point, turned out to be a kind of moulge—neither a Cauli-bage nor a Broccoli—nor could it be used as a substitute for either. Fortunately all the eggs, so to speak, were not placed into one basket, or the result would have been even worse than it was. Should any reader of GARDENING ILLUSTRATED desire to save his own seed of any special selection the foregoing should be a lesson, especially if bees have access to the garden. The hive may not be in the garden, for it is well known bees travel long distances in search of food and honey flowers, and they have a marked partiality for the Brassica tribe. Some muslin or other fine meshed netting ought before there is an open flower to be fixed over the plant so that there are no apertures for the bees to take advantage of. The same care would be needed in the case of several varieties being seeded, or they would become so much intercrossed that no reliance could be placed on the stock of seeds thus procured. It is true one sometimes meets with instances, among cottagers in particular, where seed is saved annually, and where, too,

sow a little Parsley seed with my spring Onions, and allow a few plants to remain singly and grow up amongst the Onions. When the Onions are harvested, spring Cabbages are planted, all the large leafage of the Parsley being cut close off, and by winter there is a very nice crop. The land being good and the plants standing singly, the Parsley makes fine growth. Before frosts set in I put a handlight over each of the best roots, and it is astonishing the amount of nice Parsley I get through the winter and spring. Early Lettices and Endive may be treated in the same way, and, when not wanted in spring, handlights are useful for pricking out things under, and are excellent for rooting many cuttings in.—F. A. C.

Asparagus on the French system.—In your issue of the 11th inst., in "The Coming Week's Work" for June 18th, mention is made of growing Asparagus on the French system. Would you be good enough to let me know how this is done?—T. F. C.

[What is termed the French system simply means planting in well prepared huml in trenches at wide intervals. Many English growers who are working on these lines do not give so much room as is allowed on the continent, but are sowing with the rows 3 feet apart

and 18 inches between the plants, very good heads have been obtained. Let the plants have room to do their best, and there will be more profit and more permanence.—E. HOBNAV.]

GARDEN WORK.

Conservatory.—One well-grown plant will give more satisfaction than a dozen weedy things that have been spoiled by overcrowding. No person of taste can look upon a lot of pot plants crowded together with any feeling of comfort or satisfaction. It may be necessary in some places to crowd a little in winter, but even then it would be better if one had the courage and resolution to clear out some of the old plants at the approach of winter, to do justice to those which are left. The permanent things in the horders increase in size from year to year, and require more room even if judiciously pruned. There is no excuse now for overcrowding, because most greenhouse plants for the next three months will be better outside than under glass; but the majority of plants which flower in summer will be better in our climate under glass. I am, of course, referring to tender plants only. There is no doubt the shelter of a roof does improve the flowers when they burst into blossom, but at this season the lights should, to a certain extent, be open night and day. The soft, humid air of the night, when constantly in circulation, is beneficial to all plants under glass, and it is very seldom we close the lights of our plant houses, except it may be during a gale of wind. Thus, though the plants which have completed their growth and those which are preparing for winter are better outside, the chief part of the flowering plants will come finer and better when sheltered from the weather and shaded from hot sunshine. The usual time for repotting specimen plants is as soon as they begin to grow, and though this is well enough as a general rule, it will not meet all cases. Many of the fast growing things may require more than one shift in a year, and I would rather do this than adopt what was known at one time as the one-shift system. There is often danger in large shifts of the soil getting soured by injudicious watering. In shifting on Cyclamens and other winter-flowering plants, do not crowd. Very often the plants are placed close together, with the view of opening out later, but if this opening out is delayed the plants receive permanent injury. Again, heavy shadings are not required—only just enough to break the sun's rays—and on mild, warm nights the lights may be drawn off to let the night dews fall on the foliage. The open air at this season, now that the weather is more settled, cleanses and hardens the growth.

Stove.—Be very careful about the syringing water. Unless rain water can be obtained it will be better to discontinue syringing the plants and obtain the necessary humidity in the atmosphere by damping the floors and stages. Basket plants are a great attraction where there is head-room. The *Torenia*s, especially *T. asiatica*, make nice basket plants. *Russelia juncea* is a good companion. Both are of easy culture and graceful habit, and both are old-fashioned things that have pretty well disappeared from the stove. Among fragrant plants, *Pergularia odoratissima* is a desirable thing to have. It is a fast-growing climber, and the roots should be kept under control. We have had it planted in a small bricked pit in loam and peat, where it flowered freely and filled the house, especially at night, with its fragrance. The flowers of a peculiar greenish-yellow colour are, except for their fragrance, not suitable for cutting, according to present ideas. Still, it is a desirable plant to have in a good-sized stove. We have discontinued fires for the time being, but are always ready to light a fire if there comes a change in the weather. Still, as a rule, we can do without fires in July and August. More ventilation can be given, and less water thrown about. This will hasten the plants and prepare them for removal to the conservatory or elsewhere for a time.

Cucumbers.—There is generally plenty of Cucumbers in frames now, and where there is only one house for Cucumbers the frame supply gives a chance of clearing out the

house and preparing for a fresh start for autumn and winter. Cleanliness is very important. If possible, the house should be painted, or, at any rate, if painting is not required the woodwork should be scrubbed with soap and water, the glass washed, and the walls lime-washed. The beds also should be cleared, so that all harbour for insects should be removed. It will soon be necessary to sow seeds for planting out in September. Telegraph is a good winter variety. Do not plant in very light soil. The plants bear better and are more permanent when there is a fair amount of body in the soil. Bone-meal is always useful. The best way to prepare soil for Cucumbers is to place the loam and what manure is used in a ridge-shaped heap some months before required for use. The same class of material will do for other things besides Cucumbers.

Work among Pines.—This is the time when successions are placed in fruiting pots and suckers receive a shift. Pines require a good turfy loam, not too light and suitably enriched. Bone-meal, at the rate of a 6-inch potful to a bushel of soil, is a suitable manure. Soot, also, may be added in small quantities. As regards other manure, the best time to mix that with the loam is when the loam is cut and stacked—a layer of loam or turf with a thinner layer of manure. This should be done six months before required for use, and then it becomes blended, and is ready for use when chopped down. Firm potting is necessary, and at each shift the plants should be dropped a little deeper in the pots, removing a leaf or two if necessary, so that roots may form higher up the stem. It always benefits the plants to replunge them in a stirred up and replenished bed; growing plants require more room from time to time. We need hardly say that after repotting, until the roots are working in the new soil, very careful watering is necessary, and the syringe should be used with judgment. In hot weather a light shade is necessary. Night temperature, 65 degs. to 70 degs., the last set of figures for the fruiting house, air to be given at 80 degs. to 85 degs. Close early enough in the afternoon for the thermometer to rise in a saturated atmosphere to 90 degs. or 95 degs.

Window garden.—The window garden should be treated on the same lines as the conservatory; only those plants kept inside which are effective. Others will be better outside, either in shade or sunshine, according to their needs. The routine work, such as watering, syringing, etc., should never be relaxed if the plants are to be kept in health. This is the time to give weak stimulants to plants which have consumed most of the food in the pots.

Outdoor garden.—One of the brightest objects in the garden now is a mass of Paul's Carmine Pillar Rose. It is not a fiery shade of colour like the scarlet Geranium, but a pleasant shade of carmine which does not unduly tire one's vision. Other and quieter tones are a mass of *Dictamnus Fraxinella*. This, without being bright, is interesting and curious, and it is one of the plants which is best without disturbance at least for several years. Top-dressings are good for it, as they are for *Pæonies* and other things that one can leave unmoved for a long time if their wants are well attended to, and their wants are simplicity itself—first, a thorough preparation of the site, and then an annual top-dressing. There is abundant occupation for the industrious among insects and weeds. Roses on walls will require syringing with something to destroy green-fly. Of course, this ought to be taken in hand at the time the first fly is seen and carried on persistently, and, when the victory is won, the plants will still retain their freshness. As a rule, when insects attack a plant mischief is done before the flies are dislodged, because valuable time is lost before the attack is begun. Weeds are less harmful than insects, because one can clear them off and convert them into manure; but insects have no redeeming feature. Late-sown annuals should be freely thinned. Give liquid manure to Sweet Peas. Mulch Hollyhocks and Phloxes with good manure. Phloxes are lovely border plants, but are not lasting enough for cutting, and are, besides, too massive. For cutting we want long-stalked flowers, light in build, and clear in colour.

Fruit garden.—Where Strawberries are planted for the purpose of producing runners only the first season, all flowers will have been pinched off and the runners encouraged. This it will be quite safe to do if the runners were taken from a prolific stock. The cause of what is termed blindness in Strawberries is a somewhat difficult one to trace in each particular instance. We know that badly-ripened plants when placed in heat may go blind or the blossoms may refuse to set, but we have to absolute proof that blindness is permanent. When plants are set out in very rich, loose ground, the chances are the growth will be disorganised and the plants will not bear fruit, and the wisest course is to pull all such plants up at sight. Careful cultivators are not troubled much with blind plants when good runners are selected. The summer pruning of wall and other trained trees may soon be taken in hand, beginning first with those trees much crowded with growth. There is room for discrimination in their treatment, and as the season is a backward one we need not be in a hurry. The evil of leaving the summer pruning till growth is finished is that, if persisted in, it must be followed by root pruning, but the whole business of fruit growing requires very careful individual study.

Vegetable garden.—There is always a certain amount of sowing and planting to do, but after the middle of July, even in sheltered gardens, Peas will not pay to sow, though there is plenty of glass a sowing of a dwarf early kind may be made in a frame or pit at the end of the month, leaving the lights off till later in the season. Of course, such crops offer another chance of getting a late dish or two, but they do not pay. I do not think late sown Peas do pay unless the season is a favourable one; but we have to take our chance in such matters. On difficult soils one has to rely on Spinach substitutes, and the best of these are Spinach Beet and New Zealand Spinach. The former, if sown in April or even later, will now be producing large leaves of a succulent character. A further sowing may be made now. In some districts this is used with Parsley and other herbs for stuffing meat, and is much appreciated. In late districts a good sowing of Cabbages should be made about the middle of July, and a small second sowing about the 25th of the month. In early districts make the first sowing about the 22nd, and the second first week in August. If one only sows a small packet of seeds, it is best to divide it and make two sowings, with an interval of ten or twelve days between. Sowing Lettuces and Endives for autumn and winter salads is very important. We begin to include the black-seeded Bath Cos now, and make several sowings from this till the end of September. The last sowing is left in the seed bed all winter. Endives should be sown and planted in quantity now, as the plants will not bolt. One can scarcely do wrong in sowing Turnips freely now. The Chirk Castle Blackstone is the hardest Turnip I know, and the flavour is excellent, though the hulbs do not grow to a large size. Continue to plant out Leeks and Celery. If Leeks cannot be planted in manured trenches, plant with a large peg, make holes deep, and leave the stems free. E. HOBNAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 14th.—Made a last sowing of Peas, an early kind being selected. So far as is possible, we mulch all Peas, and, if the manure gives out, something else is used. We believe in mulching anything that requires moisture. The Chrysanthemums have all been arranged in rows on coal-ash beds, with the tops of the stakes fastened to wires capable of resisting winds. At present we have not had much trouble with insects, and we have seen no rust.

July 15th.—Cut back early-flowering Fuchsias to get cuttings. We always strike Fuchsia cuttings early in August for the early-flowering batch, and, by cutting back now, plenty of young shoots is produced. Sowed Herbaceous Calceolarias. These are sown in pots in cool-frame, covered with squares of glass, and are grown cool all through till they flower. The first batch of Cinerarias has been pricked into boxes, 2 inches apart, in a cool frame.

July 16th.—As fast as the early Potatoes are lifted, the ground is prepared for cropping again. A part will be planted with Strawberries, and a part sown with late Turnips early next month. We are securing Strawberry-runners as speedily as possible for forcing and planting outside. Royal Sovereign will be grown largely for forcing, but it flowers rather too early outside. Early blossoms get cut by frost.

July 17th.—Sowed Brown Cos Lettuce. This is still one of the best autumn and winter Lettuces. We also grow Tom Thumb. It turns in quickly, and does not run so soon as the large kinds. Another look round has been given to Peach wall to tack in young shoots. The finishing touch has been given to fruit thinning. We have not done any summer pruning yet as the growth is backward; but it will not be delayed much longer.

July 18th.—Made a first sowing of Tuberges. Shifted on Begonias, chiefly Gloire de Lorraine, into 5-inch pots. Moved several specimen Bougainvilleas to conservatory. We are layering Strawberries into small pots as fast as possible. Made a last sowing of No Plus Ultra French Beans on South border. Shall sow later in pit for late use. Finished potting Tree-Carnations for winter flowering. The plants are now on coal-sheds. Mulched Tomatoes with manure. Shifted on Aralias into 3-inch pots.

July 19th.—Made up several Mushroom beds in shady spot on north side of building. Thinned shoots of Figs on south wall, and tied on to trellis. Earthed up late Potatoes. Liquid-manure is given to early Celery. Wrapped paper round to commence blanching. Nets have been placed over ripening fruits. Thinned the young wood of Red and White Currants. Insects were making an appearance on several bushes, and these have been dealt with. Made a last sowing of early Horn Carrots for drawing young.

POULTRY.

Death of hen (E. T. F.).—There is no doubt that liver disease was the cause of this bird's death, and it would be advisable to reduce the diet of your poultry both in quantity and quality, during the summer at least, or you may lose many more fowls from this complaint. It is advisable to add a good portion of Pollard or Sharps to the Barley-meal, as the meal alone is of too fattening a nature at this season of the year. This disease is hereditary, but it can also be induced by feeding on too rich foods. The best treatment of fowls showing symptoms of this disease is to give some aperient medicine, followed by a couple of grains of calomel every other day for a week or ten days. This can be given in the soft food. The homoeopathic tincture of Podophyllum is also a most useful remedy for this complaint. Dumbfles, cut small and given in abundance, together with a good supply of sharp grit, will also prove beneficial.—S. S. G.

BIRDS.

Death of Nonpareil (Zitella).—We can only repeat that the cause of the death of so many of your birds is from their being kept in a conservatory, in which position the direct rays of the sun upon them through the glass would bring about heat apoplexy. It is to be feared that the death of the inmates of your aviary will continue unless ample shade is afforded.—S. S. G.

Bullfinch with swollen claw (M. A. Matthers).—When your bird "got hung up in his cage," the joint of the claw now swollen, most probably became dislocated. You should, by careful manipulation, endeavour to return the misplaced bone to its socket, and then put the bird into a small cage without perches, and with the floor covered with Moss or some other soft material. Leave it in a quiet position where it will not be disturbed, giving it a sufficient supply of food and water within easy reach. In a few days you will in all probability find that your Bullfinch has regained the use of its leg. The red swelling may be an active ulcer brought on through the damage to the foot, and would require a soothing mode of treatment, and to be dressed with some cooling application, such as zinc ointment or spermaceti, while means must be taken to prevent the bird pecking or scratching the affected part. Let the diet be of a cooling nature (scalded

Rape-seed is the best food for these birds), giving twigs of some fruit tree as green food.—S. S. G.

Death of foreign birds (Zitella).—A conservatory is not a good place in which to construct an aviary unless the roof can be covered to obviate the direct action of the sun, as in such a position birds are subject to heat apoplexy. When so attacked they are found putting at the bottom of the cage or aviary in a paralysed condition, and if the attack has been a severe one, a speedy death follows. The same thing often happens when a cage is hung in the full glare of the sun. All that can be done in a case of apoplexy or sunstroke is to immediately remove the sufferer into a cool position, giving a little lukewarm water to drink, putting its feet into water at blood heat, and, in the case of larger birds, a little castor-oil will sometimes prove beneficial; but it is seldom that recovery is effected. I should certainly advise you to remove your birds from the conservatory, unless some means can be devised for shading from the direct rays of the sun.—S. S. G.

LAW AND CUSTOM.

Notice to quit.—If a tenant gives a quarter's notice now, he can legally remain in possession until September 29th next, or should he give up possession on or before September 20th next.—W. W.

(If the tenancy began on September 29th, or, having begun on some one of the other regular quarter days, is determinable by a quarter's notice, the tenant may, of course, keep possession until September 29th, although the notice was given on or before June 24th.—K. C. T.)

The rating of a market garden.—Eighteen months ago I took of a gentleman his kitchen garden, comprising half an acre of land, at the yearly rental of £12 10s. The garden has on it a vineyard, and some glass-houses, polling-sheds, etc., and is divided by a highway from the private grounds of the landlord. I grow Tomatoes, Cucumbers, bedding plants, etc., for sale, but the garden is not rated as agricultural land. My landlord occupies about 6 acres of land as lawn and private grounds, which are all rated as agricultural land. Should not my garden be rated as agricultural land also?—MARGARET GIBBERNA.

[If your statement be accurate, and there are no qualifying circumstances omitted, your garden should be rated in two parts. The glass-houses and other buildings should be valued separately from the rest of the garden, and should be rated in the same way as other buildings, while the remainder of the garden should be rated as agricultural land. The sum of the gross estimated rentals of the glass-houses and of the remainder of the garden should be £12 10s. If this be not so, you should give the assessment committee and the overseers written notice that you object to the valuation list, and you should appear before the assessment committee in due course in support of your objection. The lawns, flower-gardens, and other pleasure-grounds of your landlord should clearly be rated in the same way as buildings for the purposes of the poor rate.—K. C. T.]

A tenant's claim for compensation.—In 1901 I took a farm for 10 years under an ordinary farming lease, having power to cultivate 25 acres in the ordinary three or four course rotation, with permission to sell all produce; the remainder of the farm (over 100 acres) to be permanent Grass, no mention being made in lease of compensation for improvements. Independently of this written agreement, I got verbal permission from the landlord and the agent to cultivate the arable land as I thought fit and to develop a market garden, the landlord buying the fruit-trees for this purpose, in addition to which I have planted some 2,000 fruit-bushes and other garden produce. It is now proposed by the landlord to take (with my consent) some of the Grass land from my farm and make out a new lease. What form of clause should I endeavour to get inserted in the new lease to give me security for my improvements, bushes, etc., and, failing getting a new lease with such a clause inserted, what value is there for me getting compensation at the end of my existing lease for the improvements I have already made?—YORK.

[The mere verbal permission to cultivate the arable land as you choose and to develop a market garden will not give you any claim to compensation for your improvements on the expiration of your lease, and you can claim no compensation under the Agricultural Holdings Act unless you are under the Market Gardeners' Compensation Acts. You should get your landlord to insert in the new lease permission to cultivate the holding or any part of it as a market garden, and a clause to the effect that on the expiration of the lease the landlord shall pay to you the value of the fruit-trees and fruit-bushes planted by you, and the value of any improvement caused by the planting of such vegetable crops as continue to be productive for two or more years.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 17, Finsbury-lane, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Insects on a Cactus (C. R. R.).—The Cactus is attacked with mealy-bug. Lay the plant on its side and well syringe off all you can; then wash it with strong soap-suds and Tobacco-water, taking care that none of this reaches the roots. Afterwards look daily for the insects, and kill every one that makes its appearance.

Leucophyllum Brownii (B. W.).—This is a plant of extremely easy culture. It is best wintered in a cool greenhouse or frost-proof frame, and is easily propagated at any time during the summer. It makes an extremely neat and effective edging to flower beds during the summer season, and is much employed in carpet bedding.

Plants for a fernery (Fern Lover).—Of flowering plants few will thrive well in the partial shade which prevails in a fernery; but we think you might successfully grow several kinds of Dracaenas, *Aspidistra lutea variegata*, *Nertera depressa*, *Saxifraga sarmentosa*, *Urtica dioica* plants, the Cape Sundews, and fine-leaved Begonias.

Creeping Speedwell (Veronica repens) (D.).—This is a dense, close-growing creeper, covering the soil as it proceeds with a perfect soft carpet of bright green foliage, and it only needs a little occasional trimming to keep it in place. It seems to thrive well on soil that is moderately dry, and it very rapidly covers the ground. Anyone in want of a good carpet plant should try this Veronica.

Delphiniums from seed, etc. (P. S. D.).—Yes, the Delphiniums are easily raised in great variety from seed. If the flower-stems are cut down promptly after blooming the plants flower again in autumn. Rich soil or a place in the rhododendron border is not even necessary for them, though they are well worth both. They will be freely without attention or staking, either in strabuttins or boxes, and also well in open situations.

Bamboos for the conservatory, etc. (S. H. S.).—When well grown in pots the smaller Bamboos make admirable plants for the conservatory or greenhouse, or for standing in rooms; they may be used with advantage. Sprays of their glossy foliage are also among the best material which can be used in large vases of cut flowers. The kinds most favoured for the purpose in view are *Bambusa nana*, *B. mitis*, the *Trine B. nigra*, and *B. arundinacea*.

Unhealthy Marguerites (Marguerite).—The leaves are badly attacked with the grub of the Marguerite Daisy-fly (*Phytomyza affinis*). The best plan is to pluck each portion of the leaf where the grub is seen at work between the thumb and finger, and thus destroy it. Also some of the worst leaves had better be picked off and burnt. The pinching of the leaves must be followed up regularly, and the plants should not be crowded, but should have plenty of water, with some liquid-manure occasionally, and abundance of air.

Green-fly and caterpillars on Roses (F. C. B.).—If you allude to the grubs that infest the Rose buds when opening, we cannot hold out any hope of their recovery, as you overstate them by hand-picking. The tree must be gone over every day, and the grubs picked off and destroyed. Green-fly may be killed by dissolving 4 oz. of soft-soap in 1 gallon of water, straining it and syringing with this for some two or three days running, and well washing with clean water after the fly is destroyed. Colonies of caterpillars that prey upon the foliage may be destroyed by syringing with the same.

Double Zinnias (S. C.).—These plants require a deep, loamy soil, and if other conditions are suitable they will bloom freely from July until the first cut them down in autumn. There is now a very fine collection to be had, the flowers of many being as large as those of the China Aster, perfect in form, and varying in colour. For cutting they are so valuable, for, in addition to supplying so many colours, they last for a long time in water. In order to grow Zinnias well a warm situation and abundance of water are necessary.

Globe Amaranthus (Gomphrena) (A. R. S.).—These very pretty and useful warm greenhouse or tender annuals with over-lifting flowers of various shades of colour. Sow the seed in the spring—April—in pots or boxes of light soil, prick off the seedlings when large enough to handle, and afterwards pot on singly as required. Grow in a gentle heat, such as that of a hotbed frame, and remove to the greenhouse when coming into bloom during the summer. Equal parts of loam, peat, and leaf-mould, with plenty of sharp silver-sand added, will grow them well. The pots should be well drained.

Course of Grass on lawn (Z. H.).—The course running Grass on your lawn, sample of which is sent, is *Agrostis canina* (L.) Nees, and is a creeping perennial. It is most likely that pieces of the roots of this

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

"A GLIMPSE AT THE 'FLOWERS OF THE SPRING.'"

THERE is no prettier sight in springtime than a grassy bank with the early flowers showing their varied colours on this green carpet—great patches of the common single Snowdrop, varieties of the Dutch Crocus, which are lovely, deep yellow, purple, white, lilac, and white with lilac stripes. The early Crocus, *C. imperati*, I grow in the flower borders with the large-flowering Snowdrop *Elweii*. They look very well together, and come into bloom at the same time—the end of January. The grassy slope also affords a good home for some dwarf Daffodils, *Irish nans* (all yellow), common Lent Lily (*Pseudo-Narcissus*), that grows wild in many woods in England, both north and south. It sows itself and increases rapidly on my "bank." The Winter Aconite is best placed at the edge of a wood or shrubbery. The *Erythroniums* (*Dog's-tooth Violet*), their pretty green leaves spotted with brown, and flowers of a soft pink, are useful in the Grass. There is also a good white variety. Common yellow Primroses, and some of the white and lilac varieties, all single, help to adorn the Grass, and I must not omit to mention the sweet-scented Cowslip, both yellow and red tipped, and large colonies of *Aemonea spennia*, of dazzling blue, with here and there a white one. Later on the taller varieties of Daffodils, such as *princeps* and *Stella*, make their appearance. The rosy hue of the dwarf *Cyclamen Coum*, and great masses of *Cyclamen hederifolium*, which bloom in the autumn, but show well in spring, look well. This grassy bank has but a very shallow depth of earth, not more than 3 inches or 4 inches, the subsoil being shingly limestone, but it has the advantage of no long, luxuriant Grass overgrowing to smother the flowers. The bulbs have to be planted with a little good potting mould in each hole. In the borders the Snowflake (*Leucojum vernum*) is one of the early flowers, and, later, the tall *Leucojum aestivum* follows its namesake in about three weeks. Lenten Roses, planted along the border of a shrubbery, are beautiful in February and March, pure white, Apple-blossom, and deep purple being perhaps the prettiest. I have had in my garden as many as fifty blooms on one plant. They make excellent flowers for table decoration at a time when flowers are scarce, but the stems must be split up to make them last in water. They can be easily raised from seed sown as soon as ripe, but take three or four years before blooming. The stately heads of Crown Imperials (*Fritillaria imperialis*) look best on a height at the top of the grassy bank, and when the sun shines through the deep red or orange bells the effect is charming. Should you have a rather moist spot in your garden, the smaller *Fritillaria Meleagris* and *F. M. alba* will flourish there and look well with their

drooping bells or chequered flowers. There are also two other varieties—the yellow *Moggridgei* and *pallidiflora*; but I found them delicate, and they died off after a year or so. There are many kinds of hardy *Anemonea*, such as the double white *Wood Anemone* (*Anemone nemorosa alba fl. pleno*). A. *Robinsoniana* (most lovely), and the single yellow *A. ranunculoides* (this latter I have only grown in the border), that can be easily grown and naturalised in the Grass. The early Greek variety, *A. blanda*, comes into bloom at the same time as the *Winter Aconite*, and does best on a sunny border or along a south wall in rich, sandy loam. *Anemone fulgens*, the dazzling scarlet of which is well known along the Riviera, does best, I think, in well-sheltered beds, as it seems to die out if planted in the Grass. The different colonies of *Anemone coronaria* are most charming, and look very well in the beds of the spring garden. It is best to keep up the stock by sowing some every year, and pricking out the young plants in the autumn. The fair and sweet *Scillas* must be given a place. They are all charming, from the little early *biifolia* and *sibirica*, which look well just inside the green Box edging. The white var., too, is good. Then, later, you can have the *campanulata* var. or *S. nutans*, *nutans curvula* being the *Bluebell* of the English woods. There are several varieties of the white and also some mauve, such as *campanulata lilacina* and *rubra*. The early wild Tulip (*Tulipa sylvestris*), sometimes called *Duck's-bill*, the shape of the flower rather reminding one of that bird's beak, and the splendid *Oculus-solis*, deep red with black eye, very early, and therefore named *præcox* in some catalogues, are also very pretty. *Trillium grandiflorum* (the American Wood Lily) is suitable for the edge of a wood, and is very pretty. Those I have come from Canada. I am rather fond of the little grassy-leaved *Iris tuberosa*, with its green and black velvet-like flowers. It is called "*La Vedova*" in Italy, where it grows wild. I have found it growing wild in Devonshire, but I think it must have escaped from some garden.

I must mention two or three other bulbs, even at the risk of wearying my readers. *Muscari botryoides* (the Star Hyacinth) and its white variety are very pretty, and *Chionodoxa Lucilie* and *sardensis* are a great acquisition to a garden. The old-fashioned *Ornithogalum nutans* (*Star of Bethlehem*) is a pretty flower and quite hardy. Should this peep at my spring garden help any beginner in his work, I shall be only too pleased that I have noted down my small experiences.

Belleek Manor.

M. S. K. G.

SWEET PEAS—NO ADVANTAGE IN EARLY SOWING.

The present season has shown that there is little or no advantage in sowing early in the hope of obtaining an early supply of blossoms. In the early days of February I sowed my first batch, and in a temperate usually observed in a cool greenhouse the seeds quickly germinated, and the young seedlings also quickly

went ahead. In a little while the plants, which were in 5-inch pots, five to six in each pot, were placed on shelves near to the glass roof of an unheated glass-house. Here sturdy growth was developed, and the hardening off in cold-frames subsequently was easy. The first batch was placed in their flowering quarters during the latter part of March and early April. Although the cutting winds and frosts gave trouble for some weeks subsequent to the planting out, with the first experience of more genial weather their appearance quickly changed for the better, and in a comparatively short time each clump was represented by growths of an exceptionally strong and vigorous character, engendering well for a superb display a little later. These same plants are now from 5 feet 6 inches to 8 feet in height, and until July 3rd it was not possible to gather anything like a decent bunch of blossoms. The second batch of seed was sown a month later than the earlier one, and the resulting seedlings were accorded exactly similar treatment to that given to the first batch of plants. Sturdiness and progress in growth were all along aimed at. This second lot of plants was planted out in clumps in well-tilled soil, and their growth, although not quite so strong and sturdy as that of their earlier rivals, is very satisfactory indeed. In this instance the height of the plants is some 12 inches less than that of those in the first batch. The third sowing was made in late March and early April—some two months later than the earliest lot—and, although the resulting plants appeared to make but little progress at first, they were excellent when planted out in early May. Three feet or rather more is allowed between each clump of Sweet Peas when they are planted, and about 3 feet or 4 feet between the rows. This, I find, is ample space to allow. Referring again to the last batch of this year's seedling plants, their height, as may readily be imagined, is considerably less than that of either of those which preceded it. As a matter of feet, they do not exceed 2½ feet in height, and I shall be much surprised if they ever attain to the splendid proportions of the first two lots. As a rule, the earliest batch of plants comes into flower during the earlier days of June, and this has been the case when the first sowing has been much later than that observed in the present season. As was mentioned earlier in this note, I could not gather a really good bunch of flowers until the 3rd of July—almost a month later than usual. The strange part of the whole matter is, there was no difference in the time at which the respective batches of plants came into flower. The first, second, and third sowings gave exactly the same results. No one batch was earlier than the other. After all the elaborate preparations and the extra early work, to say the least of it, it is very disappointing. There may yet be an advantage, but time will tell.

The failure to produce an early crop of Sweet Peas must be attributed entirely to the vagaries of our English climate, and against these we have no remedy. The hot weather we are now experiencing has necessitated watering. Each clump is watered at least

twice a week, first with half a gallon of clear water, and an hour later with half a gallon of manure water.

D. B. CRANE.

IRISES.

Wishing to have a selection of Iris in my garden (not the large blue Flag). I thought, if not troubling you too much, you would kindly give me the names of the different sorts? Also would you please say if the yellow Iris, which is now in bloom on the banks of the river, will grow in a garden?

—FRANK WILSON.

[The genus Iris is so extensive that we hardly know what you require by a selection of these plants, omitting "the large blue Flag." If by this term you only require the typical Iris germanica to be left out, the selecting is an easy matter. If, however, you would omit all the Flag Irises, the case is not so clear. We will, therefore, assume the former, and, if wrong, must ask you to repeat your question, with fuller particulars. We may say, however, that the Flag Irises, so called, are made up of a large number of cross-bred kinds that for years past have been raised from a large number of species, though notably from such as squalens, variegata, amona, aphylla, germanica, etc. It is the numerous cross-bred forms of all these types that are collectively known as germanica or Flag Irises, and it is these of which we give you a collection, omitting the large blue that is generally regarded as typical germanica. To make the selection of general service to those requiring a set of these beautiful flowers, we give them in their sections.

In the common germanica or early-flowering group, alba, Kharput, atro-purpurea, and Purple King are the best. In the aphylla set we take Gazelle and Mme. Chereau as the finest, the latter a finely pencilled flower. In amona, Mrs. H. Darwin, a wonderfully free kind, Thorbeck, Victorine, and Duc de Nemours. In the pallida section, which is, perhaps, the boldest of all, we place pallida and pallida dalmatica at the head; to these we add Imogene, Queen of May, Mme. Pacquette, and Walmer. In the squalens section, containing the shades of bronze, copper, crimson, etc., we take Arnold's, Dr. Bernice, Jacquimiana, Judith, and A. F. Barron. In the variegata group, in which the erect petals are of yellow and allied shades, we take Darius, Hector, Honorable, aurea, Adonis, Abou Hassan, Enchantress, and Gracchus.

In addition to these are many handsome kinds that should not be absent from any garden, such, for example, as I. albicans or Princess of Wales, flavescens, aurea (a tall species, not allied to a plant of the same name in the variegata set), I. orientalis, I. sibirica orientalis, etc. Then, in the Spanish and English bulbous Irises there is a wealth of beauty not easily matched. These bulbous kinds can only be planted in early autumn, whereas the above kinds may be planted for several months in the year, and, indeed, could be now replanted if given every attention after. The yellow Water Iris (I. Pseudo-acorus) may be grown in the garden in any quite wet position, and frequently in rather heavy soils.]

AURICULAS AND POLYANTHUSES.

Now that these hardy spring flowers have done blooming it is wise, if it is desired to increase any of the plants, to lift them, first picking out the flower stems, then dividing the plants into single crowns with a portion of root attached to each, and at once dibbling them out into fresh, well-manured soil under a north wall or where it is shaded during the day. The soil is now so moist that new roots will soon be formed and good growth follow. Plants thus treated, if cared for during hot weather by giving them an occasional watering, will flower well the following spring if transplanted with balls of soil in November. But it is desirable to take as much trouble as possible

really good varieties, as both plants can be so easily raised from seed. I have invariably found spring dividing and replanting give better results than doing it in the autumn, as whilst new roots are always formed in the spring, none are formed in the autumn, hence then the plants are dependent on their old roots. These will, if transplanted with balls of soil attached in the autumn, soon become established in the soil, and carry fine heads in the spring. Where annual seed saving from a few specially selected and marked plants is practised it is well to gather off all seed-stems from other plants, as seed bearing is somewhat exhaustive. Those carrying seed will greatly benefit if they occasionally have during hot, dry weather a soaking of water, and that may be followed by putting a thin dressing of old pot-soil round each plant. In each case the pods carrying seed should be not only allowed to become brown, but even to partially burst, as in such case the seeds are thoroughly matured. The entire truss of seed-pods may then be gathered and be laid out on paper to ripen. Sow the Auricula seed in shallow pans or boxes in August, and keep in a frame for the winter, but the Polyanthus seed may be sown also then outdoors for the plants to stand the winter.

A. D.

A FINE TREE PEONY.

My sister (aged 12) and I (aged 10) are sending you this photograph of our Tree Peony for your paper. It grows on the south side of our house in the gravel, and is very lovely. It

Old Tree-Peony by doorway. From a photograph sent by Mrs. Lowndes, Little Comberton Rectory, Peshore.

must be very old, as when our great grandfather lived here he was very fond of it, and used to have the women out of the village up when it was out in blossom every year, and make them count the number of blossoms, and to the one who counted them right he gave a prize. This year we counted 172 blossoms and buds. We are sorry to take the photograph before more blossoms were out, but we are going to school to-morrow.

W. L.

TUFTED PANSIES.

SOME GOOD YELLOW SORTS.

SINCE the introduction of rayless Tufted Pansies some few years ago there has been a wonderful advance in those of a yellow colour. Charming as are the older rayed sorts, as represented by Lord Elcho, Bullion, and a few others still in commerce, they cannot compare with the rayless varieties of recent introduction. It must be admitted that of the large number of new sorts added each year to the list of those already in commerce one here and there will not fulfil all that is expected of it. In this way, therefore, those of sterling worth remain in cultivation, and of such sorts there is now a goodly list. Various raisers have done much in recent years to improve these flowers. Good varieties in this colour which have come under my observation are:—

SUNSHINE.—A large, handsome rayless flower of splendid substance, and of a deep yellow colour. The habit is not so good as in many others, but its constitution is robust.

KLONDYKE.—Like all Dr. Stuart's novelties, the habit of this plant is all that can be desired. It is tufted and compact, and develops

its blossoms on erect foot-stalks well above the foliage. The flowers are of good size.

Mrs. E. A. CADE.—This is an ideal sort for the flower garden, blooming freely on stout, erect foot-stalks, and possessing an ideal tufted habit of growth. Its constitution is robust, the smallest pieces quickly developing into pretty plants. Grouped in dozens, this variety makes a most effective display, its bright yellow blossoms, with an orange eye, and of circular shape, possessing plenty of substance.

NELLIE RIBING.—In this variety we have another splendid Tufted Pansy. Both early and late in the season the blossoms are slightly rayed, but in the warmer weather they are quite rayless.

MELAMPUS.—Although this variety was introduced in 1830, it is comparatively unknown. Its habit of growth is perfect, and each flower stands up erect.

PENSEE D'OR.—This is one of the best of the late Dr. Stuart's gems. When in good form the plant, which is not so robust as one would like, is literally covered with dainty and somewhat fragile-looking blossoms of the richest golden-yellow. The colour is beautifully clear and rich, and the footstalks are rather slender. In its colour, it may be safely stated, it is one of the best of its kind.

KITTY HAY.—Although one of the earliest of the rayless yellow sorts, this is still one of the most effective kinds we have. On one occasion, when quite a large number of yellow sorts was planted in beds consecutively, the brilliancy of this variety was most pronounced.

ABOLLY POPE.—This, another of the earlier-raised rayless yellows, has taken some years to become known, and now it is being largely used. At Waterlow Park this variety is being freely planted, and already its large, handsome golden-yellow blossoms are making a welcome display.

PEMBROKE.—This variety has been more instrumental in popularising the rayless Tufted Pansies than any other. Its habit is not so dwarf and compact as one would like to see, yet it is a beautiful plant when plenty of space is accorded it. It is very free blooming, and each flower is borne on a long, erect footstalk.

SYDNEY.—The blooms of this plant are identical in form with those of Pembroke. It is said to be a seedling between the variety mentioned and A. J. Rowberry. The colour, in this instance, is a distinct shade of bright yellow. In growth it is also similar to Pembroke.

D. B. CRANE.

CHINA ASTERS.

To see China Asters at their best they should be planted in beds, or in large masses on borders, as in the illustration. It is useless to expect this, or any other similar plant, to produce a good effect in the garden when planted singly, or in twos or threes, as is frequently done. Straight lines or rows of them are even worse, but, unfortunately, very common in gardens. This kind of planting cannot be too strongly condemned, since it produces formality, which should be rigidly excluded from the garden. Besides planting them in masses from 1 yard to 2 yards or more in diameter on the mixed border and margins of shrubberies, they may also be grouped among Roses on beds or borders. This method of planting China Asters should be more common in gardens, for they do much towards brightening the beds and borders at a time when colour in them, so far as Rose-blossoms are concerned, is at a discount.

CULTURE.—China Asters require a rich, deep soil. It should be heavily manured and deeply dug the autumn previous to planting, and then, if otherwise judiciously managed, a very fine effect will be produced. Grown on poor soil, the plants generally present a miserable, starved appearance, looking but little better than a mass of weeds. The best Asters I ever saw were growing on a newly-made Vine-border, with which enormous quantities of bone-meal and half-inch bones had been incorporated. The plants were remarkably vigorous and the flowers unusually fine, but, of course, the practice of growing them on Vine-borders is not to be recommended. Another point that requires close attention is the raising of the plants from seed. There is no doubt the majority of growers sow the seed too soon, the result being weakened plants and consequently poor

blooms. Seed sown in well-pulverised soil on a south border in April will give much better results than that which is sown in heat in March. If considered necessary, and it is a good plan to adopt in late localities, the seed may be sown in fine soil and covered with a handlight, or in shallow boxes, and placed in unheated frames. In either case it should be sown thinly, and thus the labour of transplanting averted. Of course, to prolong the season of flower, it is advisable to make one or two sowings—say, from the end of March till the last week in April. In this case a little heat is beneficial for the first batch. When raised thus under glass, however, the plants should have a plentiful supply of air, so that they may be from the first hardy and sturdy. In this practically lies the secret of Aster cultivation. If ready, the plants may be transferred to their flowering quarters any time after the second week in May. As to

VARIETIES, these are numerous and sufficiently varied to suit the tastes of the most fastidious. There are among the taller-growing kinds the Chrysanthemum-flowered, the Peony-flowered, and the quilled Asters, all useful in their way, but scarcely so good for garden decoration as some of the dwarf and more compact varieties. For growing in beds

bulbs must not be disturbed. If growing in a loose, friable soil, let them stay there until by their leafage they show that the soil is exhausted. They are so very cheap that it pays well to plant every year, and so make sure of their flowering—i.e., if good, strong bulbs are purchased.)

Pyrethrums.—A cutting away of spent foliage and blossoms at once will ensure Pyrethrums blooming again in the autumn, more especially if, as new growth proceeds, the plants are given liquid manure. Although double sorts are very beautiful and free blooming, one cannot overlook the fact that every year the taste for single varieties is increasing, and this is not surprising when one remembers how light and graceful they are, and altogether better adapted for cutting. Reine Blanche, pure white; Gorgo, carmine; Ayrshire, crimson; Jubilee, crimson-scarlet; Mary Anderson, flesh; Warrior, purple; Alsica, white; Othroleuca, sulphur-yellow; and Behnke, bright rose, edged white, are some of this deservedly popular section. Pyrethrums grow rapidly when planted in good loam into which has been dug rotted dung, and are a feature in many a border. The fact, however, seems to be lost sight of that useful blossoms may be gathered in the autumn if after flowering in June and

their colours are rich and varied. Those who have never grown them should sow seed now. —WOODBASTWICK.

Iris pallida.—Will you kindly advise me what treatment to give to a plant of *Iris pallida* that has been in one place about ten years? It looks perfectly healthy, but seldom throws up more than one flower spike. Ought it to be manured or re-planted?—M. J. V.

[You ought to divide the clump into single crowns and move to fresh quarters, which should be deeply dug and well manured. The best time to move Irises is just as flowering is over, and, if well attended to during the summer in the way of water, many of the crowns that have been moved will throw up bloom in May and June of next year. Your soil is exhausted, hence the failure to bloom.]

Rockets.—As with other garden flowers, the season has been a late one so far as Rockets are concerned, and June was well advanced ere they bloomed. I am old-fashioned enough to still cling to these blossoms that thirty years ago were considered indispensable in the borders, and, though time has brought about many changes, the white Rocket is yet highly esteemed by many. The double white variety of *Hesperis matronalis* is compact in growth, may always be depended upon to flower, and, when understood, is not difficult to manage. I have

China Asters in the border. From a photograph sent by Mrs. F. C. Watson, Great Stoughton Vicarage, St. Neots

one are better than the dwarf Victoria and the smaller forms of the Chrysanthemum-flowered. Many of the pompon kinds are also effective when seen in masses, though I like better the recently-introduced Comet. This is one of the finest Asters in cultivation, and can scarcely be too extensively planted. It is rather a tall grower, but the blooms are charming, being of a white and light pink shade, and closely resembling those of a Japanese Chrysanthemum. It is invaluable for cutting as well as for making a good display in the flower garden. No matter what varieties are used, the practice of mixing the colours should be discontinued. By this method the China Asters will be seen at a disadvantage. Masses or groups of one colour in each are much more effective in borders than three or four plants and of as many shades. The same applies to them when grown in beds. No one ever thinks of mixing various colours of Pelargoniums in one bed, and therefore why should Asters be seen in a mixed medley of colour? Planted in groups of one colour only, the China Aster is one of the most showy flowers in the garden in late summer. T.

NOTES AND REPLIES

Spanish Irises.—What is the best thing to do with Spanish Irises after flowering? Will the bulbs flower again next year?—E. M. M.
[The new roots of this Iris begin to move before the flower stalk has withered, and the

July the old foliage is cut away to make room for new growth. Dividing the roots in the spring is the mode of propagation most in favour, and is, perhaps, the readiest, but Pyrethrums may be raised from seed with little trouble, and the time for sowing is the present, on a warm border out-of-doors, subsequently pricking them off and planting in autumn. One of the greatest mistakes that can be made with them is to leave plants to themselves for years without dividing. They not only monopolise too much of the space in the borders and thereby liable to swamp other things, but become weak in growth, the flowers puny, especially those proceeding from the centre of the clumps which fail to get sufficient nutriment. Divisions at stated periods should be made, as it is only by so doing that one is able to procure good blooms.—TOWNSMAN.

Pentstemons.—Some Pentstemons, rich in colour and flowering freely, which I saw recently were propagated last August from cuttings and kept in a cold frame all winter. As is known, they may also be raised from seed, and if sown now and afforded some slight winter protection will furnish plants for another season. Too many forget these charming old flowers, and instead of encouraging biennials are content to grow the same beds of annuals year by year. I always recommend Pentstemons because they are not liable to any particular disease, may be grown with the merest winter covering, flower abundantly and

heard some people complain of their inability to keep Rockets beyond the second season, but the one thing needful is to see that they are annually taken up and replanted in fresh soil, trimming them and taking away any old portions, planting the new crowns in fresh quarters, and, as stated, in new material which should be fairly well manured. All the failures I have met with have been amongst plants that were left to themselves, and have, as one grower put it to me, "cankered." That is why in some gardens one may find newly-imported plants flowering. Autumn is a convenient time to split them up. The single sorts, both "whitish" and purple, though not nearly so compact as the double, are very sweet, and some in bloom in my own garden have been much admired. Seed may now be sown for another year's flowering. The single sorts are perfectly hardy, and will stand unprotected the severest winter.—LEAVERST.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Miss Mabel Gaisford, The Grove, Dunboyne, for *Scilla campanulata* in the rock garden; 2, Mr. Geo. E. Low, Dublin, for *Schizopetalou* in the rock garden.

RES. OF ILLINOIS AT
URBANA-CHAMPAIGN

INDOOR PLANTS.

HERBACEOUS CALCEOLARIAS.

By the time the latest plants have passed out of flower the gardener must think about sowing seed for next year's display. Various dates as to the time the seed should be sown are given by different growers, some saying towards the end of July or even the middle of August is soon enough. I like my seed to be sown before the month of June is out, seeing the plants require a long season of growth, and are not likely to get too large if given quite cool treatment, as they should have from the time the seed is sown until the plants are thrown away. Coddling in any shape or form is detrimental to the Calceolaria and a sure forerunner of aphid, the greatest enemy the plant has.

SOWING THE SEED.—The seed is best sown in pans, which must be clean and well drained and filled to within an inch of the top with fairly fine loam and leaf-soil, with a little sand, after placing a little rough leaf soil or Moss over the corks. Make the surface of the soil even, and water a few hours previous to sowing, using a fine rose on the can for the work. If the pans are stood in a frame kept close and dark, it is seldom any water is required until the seedlings are through the soil, germination taking from a fortnight to three weeks. Do not cover the seed with soil, as it is so very minute the merest sprinkling of fine silver-sand will suffice; in fact, unless in experienced hands, it is wisest not to put any, but as soon as the seed has germinated sprinkle a pinch through the finest sieve. Remove the covering immediately the little plants appear, and tilt the lights a bit for a few days, carefully watering, or damp will set in and the plants soon disappear. Also keep an eye that no slugs are about, as they very soon devour the seedlings.

POTTING.—As soon as large enough to handle, and they require the greatest care just then not to bruise them, prick them out into pans of light soil 2½ inches to 3 inches asunder, water in, and shade from the sun at all times during the summer. By the time the foliage meets they should be placed in 3-inch or 4-inch pots, carefully lifting with a label, and taking care not to break the foliage in the operation. At this potting the soil need not be rich. To 2 bushels good loam add three parts of a bushel of leaf-mould and sand (coarse silver or river) to keep it porous. For the final potting rather over a peck of well-decayed cow-dung will make with the above a good compost. After potting place the plants on a cool north border under a frame or in a brick pit in a similar aspect. Shade for a few days and keep close, but give abundance of air when once growth has started again. In this position the shade can be dispensed with earlier in the afternoon, and the plants should be dewed overhead two or three times daily, and constantly examined for aphid, shifting them into a house and fumigating at once if Tobacco-powder will not destroy them. At the next potting 5-inch and 6-inch pots are large enough, and these should carry them on until spring. Keep the plants in the pits or frames until hard weather sets in, as they thrive much better here than on shelves.

INDOOR TREATMENT.—When brought indoors, place in as light a position as possible and within a foot of the glass-roof, using no artificial heat unless really necessary. The house should be fumigated about every ten days, as it is much better to keep aphid away than to try and eradicate it when once it has got a footing. Dew the plants overhead about 10 a.m. on fine mornings, as they dislike a dry atmosphere. Towards the end of February shift the plants into 7-inch and 8-inch pots, potting fairly firm and guarding against too free a use of the water-pot, only giving a supply when really on the dry side, or the plants will soon get sickly, and no coddling will bring them round. Speaking generally, by the middle of March the plants can again be placed in pits or frames if carefully matted at night, and, while a few degrees of frost do them no harm perhaps, they are certainly no better for it. When you find the roots working around the side of the pot, a weekly application of weak manure-water may be given, but avoid strong doses at all times. Secure the growths to neat stakes by means

and place in the conservatory or greenhouse as soon as the blooms begin to open, keeping a dry atmosphere overhead now, or the flowers soon spot and decay. Though it takes nearly a year from the time the seed is sown to have the plants in bloom, a batch of Calceolarias, well grown and nicely flowered, is admired by everyone, the varied markings and colourings arresting attention. J. M. B.

SPIRÆA JAPONICA MULTIFLORA COMPACTA.

In this, which is very compact in growth, the flowers are produced in denser plumes than in the type, their colour similar to that of the ordinary form so familiar to all. It is certainly worth growing for its distinctness, and is just as easily forced as the ordinary *S. japonica*.

HEATING A LEAN-TO.

(REPLY TO "BELFAST.")

In respect to the boiler, you had best effect a sort of compromise by half sinking it. There is no advantage in having the pipes quite near the floor. At the same time it is not desirable that the pipes should be so near the staging as to cause constant drying up of the plant-thereon, and in turn necessitating much excessive watering. Therefore, if on entering the house your top or flow pipe is 1 foot high, you will, by giving each pipe a ½-inch rise in its length of 9 feet, get to the other end without much trouble. But you must ever bear this in mind, that the more the boiler is under its work, so much easier is the working and so much quicker the circulation. Quick or rapid circulation in such case is responsible for keep-

Spiræa japonica multiflora compacta. From a photograph sent by Mr. W. Johnson, Trafford Hall, Chester.

Some admire it, but in my opinion it is not equal to the ordinary kind, forming, as it does, a much denser mass of bloom, and consequently, when at its best, it is wanting in the lightness and elegance of the type. There is little doubt that it originated from the golden-veined variety, which, except in the marking of the leaves, is a counterpart of the other. The golden-veined variety is an old inhabitant of our gardens, and is during the first part of the season very pretty, for by the time the flower-spikes are fully developed the leaves are far greener than when they at first expand.

T.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, which will be mailed to you.

ing up a better heat, the water getting back to the boiler but little reduced in temperature, whereas in a slow or sluggish working the water may be nearly cold on returning to the boiler. Indeed, this quick rise into the chief or first flow pipe, and the subsequent rapid rise, are among the chief factors of satisfactory heating. It is where the water gains or receives but little impetus from boiler to pipe, and where there is no corresponding fall of the return pipe, that much sluggishness of action and general unsatisfactoriness ensue. If, therefore, you have an idea for working the flow pipe off the boiler nearly at dead level, we say, don't, but so sink your boiler that a 6-inch rise is afforded either at the boiler itself by means of a bend or swan-neck connection or the like, or as soon as the house is entered. It will be easier to attend to these details now than to have the trouble later. With the pipes fairly high, as suggested, it is

possible you may keep up to 45 degs. with the one flow and one return on one side, but it would be easier done, say, with two 3-inch pipes on top running parallel as flow pipes, discharging into one 3-inch return below them. The radiating surface from a single 3 inch pipe is not great, and it would mean, if you maintain the heat, not only much attention to the fire, but also that the pipes of necessity would be heated up to an excessively high, and heat, the latter the plague of the amateur plant grower, and also the forerunner of hosts of shortcomings in the plants and of the appearing of not a few insect pests. Therefore, a few pipes overheated are quite opposed to success generally. The pipes can readily be disconnected, though you may have to sacrifice a portion here and there where cutting becomes a necessity. In the new work we suggest the use of rubber rings as not only more economical in point of actual cost in time, etc., but their use renders very easy any future alterations.

THE STAR CINERARIA (CINERARIA STELLATA).

To those who have partially tired of the perfection of form (so called) of the florists' type of Cineraria has been afforded no small amount of pleasure in the introduction of the star-like varieties. The florist, no doubt, who adheres rigidly to the rotund form of blossom, with its almost mathematical shape, will not view with any special interest this more recent introduction, but look upon it with disfavour. Without attempting to detract from the merits of the florists' type as now grown, it must be stated that this new development of the Cineraria has very much to recommend it. To many it will come as a welcome relief, affording fresh variety to a charming class of spring-flowering subjects. As conservatory plants they are specially to be recommended, being more easily associated with other and taller subjects than the florists' Cineraria. Already there is a pleasing variety of colour. When cut, these Star Cinerarias have much in their favour, being better for arranging in many ways than the others are by reason of the length of stem; whereas, from the point of effect also an advantage is gained by the less density of the corymbose heads of flowers. The cultivation needed is nearly the same as for the usual run of Cinerarias. Whilst smile to a certain extent is beneficial, too much will be harmful. Overpotting, again, should be guarded against, also overcrowding.

NOTES AND REPLIES.

Hemanthus Katharinae.—I herewith send you a photograph of a plant that I should be pleased if you would kindly give me the botanical name, cultural details, etc. It is beautiful mixed with other plants in my greenhouse. I have taken GARDENING for some years, and find it excellent for reference. I am 81 years of age, and still am able to look after my greenhouse and part of my garden, my gardener doing the rougher work.—CHAS. GOOD.

[The plant represented in the photograph is *Hemanthus Katharinae*, a native of Natal, from whence it was first sent to Kew in 1877. The genus *Hemanthus* is an extensive one, all the members of which occur in the southern half of Africa, some of them which are natives of Cape Colony succeeding with greenhouse treatment; but for those from the Congo district a stove is necessary for their successful culture. Some of the species are difficult to grow, while, on the other hand, many of them readily conform to ordinary treatment. One of the most amenable to cultivation is *H. Katharinae*, which will thrive either in a greenhouse or under warmer conditions. The soil best suited for this *Hemanthus* is two-thirds good yellow loam to one-third well-decayed manure, or, failing this, leaf-mould, with a liberal sprinkling of silver-sand. Repotting, if necessary, should be done as soon after flowering as possible, but it resents disturbance at the roots more than is absolutely necessary, and provided the drainage is good and the roots healthy, it may be kept in the pot

several years without repotting, but should be assisted during the growing season with an occasional dose of weak liquid-manure. After flowering encourage the plant to make healthy growth by giving it a good position in the greenhouse and keeping it properly watered, then, as autumn comes on, less water will be needed. During the latter part of the summer it should be well inured to sunshine in order to thoroughly ripen the bulb. Throughout the winter scarcely any water will be needed, but with the return of spring the supply must be increased. Then the leaves and flower spike will in time develop. In winter the temperature of the structure in which it is kept should be allowed to fall but little if at all below 50 degs., though if the soil is very dry 35 degs.

over when new growth has fairly shown itself, for at this time of the year, when so many stand them out-of-doors, one is tempted to give them insufficient water. It is the greatest mistake to administer mere surface-sprinklings, as all subjects potted for the most part in peat, like Azaleas, should be thoroughly saturated when watering is needed at all. Keeping them in a partly shaded aspect will minimize considerably the labour involved in watering, and assist the plants also.—W. F.

Hiding an edging in greenhouse.—Will you be so kind as to tell me what you consider would be the best and most practical (2) most quick-growing, (3) and hardiest species or trailing plant to train along and over the little wooden ornamental edging to the stages of my conservatory? The edging is 5 inches high, it looks very neat as a finish to the stages or shelves, and hides the

The Star Cineraria (*C. stellata*). From a photograph sent by Messrs. Wehl & Bois, Stourbridge.

may not cause any ill effects. Other reliable species that may be grown in a greenhouse are the Blood-flower (*Hemanthus coccineus*), with bright red flowers usually at their best in August, and *H. albidus*, in which the blossoms are white.]

Azaleas.—It depends largely upon the summer treatment of Azaleas as to their chances of blooming another year. More plants are starved in the summer than are killed by frost in winter. In many instances, instead of being kept in the greenhouse after they have done blooming to encourage young wood, they are sent straight away into cold-frames, where, owing to neglect in watering and a too radical change of atmospheric conditions, they either die off or fail to produce buds for another season. Nor is the danger

pots newly that stand behind it. At the same time, a friend has suggested that pretty a grass-creep would be trained upon and along it, and says *Asparagus Sprengeri* was most successful and rapidly growing thus used in a small conservatory she had one to do with. I have an *Asparagus Sprengeri* in a hanging-basket, but I cannot say time has gone rapidly, and, at the same time, the branches stand up rather stiffly. I shall be much obliged for your advice.—A WATERER.

[Your best plan will be to grow *Isoplexis gracilis*, *Panicum variegatum*, *Helianthus* or such as *Campanula isophylla* and *D. l. Mayi* in pots, standing the pots behind the wooden edging and allowing the plants to hang over. In this way a fine effect ought to be produced.]

An unhealthy Camellia (*C. K.*)—You do not say how the *Camellia* has been treated as to its roots. Probably the soil in the centre of the ball of roots is dry, and, if so, that would account for the failure. Examine the roots, and, if dry, place the pot in a cask or large tub of water for a few hours, until all the earth has been thoroughly moistened. The pots should be well drained, and the plants pressed down firmly around the roots in the repotting.

ROSE NIPHETOS IN THE OPEN AIR.

I see in a recent issue "Woodbastwick" asks us to the experience of others with Niphetos, and another just below speaks of the failure of Climbing Niphetos in a cold greenhouse. They may like to know that here, on a cold part of the Wiltshire Downs, 400 feet above the sea, I have had a Climbing Niphetos for eight years on the south wall of my house in full and lovely bloom every year, with the great white bell-like flowers hanging down among a mass of other creepers. It rises up to the roof, and I thought after the bitter cold of the whole year, from January to June, I should have few blooms, but directly the heat began the buds opened among the tangle of Clematis montana and Honey-suckle, and now it is beautiful to see the pure white large blooms mixed with W. A. Richardson covering the higher part of the house, while below I have Safrano, l'eshunt Hybrid, Climbing Capt. Christy, l'elme Forester (also up to the roof), General Jaqueminot and the old Pink China, all on a background of Ampelopsis Veitchi and Ivy, and I think the Roses rather like the shade of the leaves and the shelter. Reine Marie Henriette also does grandly on my stone porch. The soil here is all chalk, and I often wonder the Roses do so well with such shallow earth above, but where Ivy and creepers help to impoverish. I often give some gallons of seullery sewage on the south border during the dry season. — *GEORGINA H. OSBORNE, Salisbury.*

— "Woodbastwick" asks if anyone can report well of Niphetos as an outdoor Rose. I live in E. Devon, and had a Niphetos Rose against the north wall of my house, which reached to the upper windows, and last summer it was a mass of enormous flowers. The tree was unfortunately killed, and last winter I put a very small plant of the same kind of Rose in its place. It has grown very well, and had a dozen or more good blooms this summer. — *TALBOT.*

— I see in this week's issue of GARDENING your correspondent "Woodbastwick's" enquiry about the Niphetos Rose flowering out-of-doors. It may interest him to know that in my garden in Bovey Tracey, South Devon, I have a Niphetos Rose which has been flowering freely for the last three weeks. It is growing up the outside of the house, and is a good height. The house wall faces due south. The Rose is unprotected, except by the side of house and window angle. I have lived here for more than six years, and I think each year the Rose has flowered well. I wish I had a good photograph to send to show you how well the Rose has grown, but I enclose a had little "print" which may give you some idea. — *E. M. ANDERSON, Pimley, Bovey Tracey, S. Devon.*

— Having seen "Woodbastwick's" note in GARDENING ILLUSTRATED for July 5, re "Niphetos as an Outdoor Rose," I write to say that I have seen this Rose blooming in profusion this year at Ilitcham Rectory, Suffolk, on the south-west wall of the house, also on the high wall of the kitchen garden, south aspect (a very warm corner). The blooms on both trees were mostly $3\frac{1}{2}$ inches across, all pure white, with strong stems. Hundreds of blooms have been cut, and this is about all the pruning they get, except cutting out the old wood. I have never seen such perfect blooms of the Niphetos before, not even in a greenhouse. I only wish I could have enclosed a photograph of one or other of the trees. The one on the house was planted four years ago in a border about 2 feet wide, with Climbing Lamarque and the Crimson Rambler quite near it. No particular care has been taken as to soil, etc., as this part of East Anglia is noted for good Roses. The soil suits them so well, the famous Rose nurseries at Colchester being within twenty miles of us. — *HOPE COCKBURN, The Cottage, Brideston, Ipswich.*

— In your "Notes and replies" in GARDENING ILLUSTRATED of July 5, "Woodbastwick" asks if any person has been successful with a Niphetos Rose in the open after the terrible spring we have had this year. I have

in the open a Niphetos planted three years ago last October. Last year I had quantities of beautiful blooms off it, and it grew to about 7 feet high, and I trained it on fan-shaped wires. In the autumn I protect it as I do the other Teas—viz., 6 inches of rotted manure round the roots. It suffered very much this spring, and I had to cut away a lot of dead wood; but now it is recovering very fast, and has seven beautiful huds on it, and it is throwing up beautifully healthy new shoots. The soil is very poor, and I am at least 500 feet above sea level. I have also been very successful with a Maréchal Niel against the house. I have gathered about thirty beautiful blossoms off it this year, and it looks extremely healthy. Oddly enough, delicate Teas do better with me than those marked "hardy." Will you be kind enough to answer the enclosed list of questions in an early number of your valuable paper, to which all true flower gardeners look forward with pleasure to receiving each week? — *BROOMCLIFFE, Llandiloes, N. Wales.*

ROSES FOR EXHIBITION.

(REPLY TO "WOODBASTWICK.")

THERE is a growing desire for exhibiting Roses, and we are very pleased to note it, as it must tend to good cultivation, although it should not deter us from planting the many beautiful garden Roses that yield, perhaps, the greatest amount of pleasure to the grower. We hope to have an article very shortly dealing with all that appertains to the cultivation of the Rose for exhibition. In answer to your queries, we should say if you are prepared to wait two years, it would be highly desirable to plant some well selected stocks in your prepared beds and bud them there, but by so doing you would lose a season. For our part we should rather plant the beds this autumn with good one-year-old plants from a reliable source, and plant some stocks in a reserve garden to provide good blooms of such kinds as are best on maiden plants. If you adopt the practice of severely cutting away all old wood and rely upon the young wood for your blooms, you will be able to exhibit on an equal footing with your rival who grows a number of maiden plants, and in some seasons, such as the present, you would have a better chance, as it is mainly from cut-backs that exhibitors are showing, the maidens being very late this year. One well ripened growth upon each plant is preferable to a number of small shoots. This one growth will produce two or three other growths, each carrying a bloom, and this is quite sufficient for one plant to bring to perfection. It is for this reason that exhibitors will plant their bushes close together, rarely placing them more than 18 inches apart. You say your new ground is especially suitable for Teas and Hybrid Teas. By this we presume the soil is inclined to be light. You would do well to grow a good number of the best Hybrid Teas, and you cannot discard the Hybrid Perpetuals; indeed, they should predominate. In the collection of 72 varieties that gained the champion prize at the National Rose Show this year 38 were Hybrid Perpetuals and 22 were Hybrid Teas. What we should strongly urge you to do would be to grow about 50 good kinds, and have as many of each as you have room for, 10 to 20 of each being none too many. We should also recommend you to peruse the little pamphlet on planting Roses issued recently by the National Rose Society. It can be obtained from the Hon. Secretary, Mr. E. Mawley, Rosebank, Berkhamsted, Herts, for seven stamps.

NOTES AND REPLIES.

Yellow Roses for light soil.—Will you kindly tell me what are the best yellow Tea Roses for growing in a very light soil 600 feet above sea level? I find Tea Roses do better than H.P.s.—*BROOMCLIFFE.*

[The following kinds are all good growers, and should succeed well with you if the soil is carefully prepared by deeply digging and freely manuring it with well decayed cow-manure. Procure the plants on the Brier if you cannot obtain them on their own roots. The varieties we advise are as follows, taking them in their order of merit: Rêve d'Or, Céline Forester, Duchesse d'Auerstadt, Solfaterra, Billiard and Barré, Belle Lyonnaise, E. Veyrat Hermanos, Climbing Perle des Jardins. We also think

you would be able to grow the charming little Cluster Rose Claire Jacquier, and also Gardénia, a most beautiful canary-yellow bud. Why not try a Maréchal Niel? Select a really nice sunny corner, and plant a well-rooted half or dwarf standard. If the soil is light, Tea Roses should flourish admirably, but, of course, they want more liquid-manure than Roses in heavier and more retentive soils.]

Rose W. A. Richardson in a light soil.—What is the best mode of growing W. A. Richardson Rose in a light soil? The aspect is S.W. to S.E.—*BROOMCLIFFE.*

[We have found this Rose succeed best in a strong, clayey loam of good depth, and plants should be either on the seedling Brier or hedge Brier. You would, of course, need to make special preparation for a plant of this Rose, as your soil is so light. If you dug out a hole, 3 feet wide and 3 feet deep, and filled this with a similar amount of clayey loam, with which some well-decayed cow-dung is incorporated, you would find no difficulty in the successful culture of this lovely Rose. As a rule, such clayey loam is obtainable in almost any neighbourhood, and the local nurseryman would doubtless procure it for you. Failing this, a liberal amount of cow-manure incorporated with the present soil, adding some turf that perhaps you can obtain, would answer nearly as well, especially if the Rose has copious waterings of liquid cow-manure from end of May until blossoms show colour. This and similar Roses when planted against hot walls should be carefully watched and afforded plenty of moisture at the root. Unless a really vigorous growth is produced, good quality blossoms cannot be expected.]

Rose Niphetos in a pot.—Would you kindly tell me what is the matter with my Rose Niphetos? It is in a large pot, and was repotted last year. It throws out fresh shoots and buds, and, except that a few leaves have a tendency to curl up, looks healthy; but the buds drop off before opening—one or two of them when opened were found to be decayed inside. There is no green fly on the leaves, and I cannot think what is wrong with it. There is a nice profusion of green leaves. I am sending you a bud, though this one does not look decayed inside as the others did that fell off. I took this off, thinking it would have gone like the rest; but it does not seem to have commenced decaying yet. Last year two Roses dropped off in the same way, but they had begun to unfold. The year they drop when quite small and green, I keep the tree in a very sunny window facing south.—*NURSERIES.*

[This beautiful Rose is not at all a suitable kind to grow as a window plant; in fact, few, if any, of the true Teas can be cultivated in this way. Some of the sturdier Hybrid Teas would doubtless succeed better. From your account of the buds decaying we should say that the roots are kept too wet, resulting, possibly, from insufficiency of drainage, or it may be you have given the plant too large a pot. When Roses are grown under adverse conditions, as, for instance, in rooms or windows, it is always desirable to keep the pot rather small and endeavour to have it full of roots. Such plants do not require repotting very frequently. Every second or third year would suffice. If possible, we should advise you to plant out this Rose into the garden at once. It would recover far better than if you keep it in the pot. Dig out a hole 2 feet wide and 2 feet deep. Return most of the soil, leaving a hole a little larger than the ball of earth. Save removing the crocks, you must not disturb the ball at all. After setting in the hole, tread the soil firmly round the plant. A position sheltered from north and east would suit the variety best.]

A new Polyantha Rose.—One can imagine a mass of the beautiful little novelty, Schneewitchen, to resemble a miniature snow storm, the flowers being produced in such rich profusion. It is a seedling from Aglaia crossed with a seedling, the parentage of this latter being Parquerette and the Tea Rose Souvenir de Mme. Lévet. The new comer has the charming creamy-yellow buds of Aglaia, and every tiny bud is as perfectly formed as the Tea Rose just mentioned. The fine clusters when expanded are in effect white, although on close examination one detects a suffusion of palest yellow. The fragrance is that of the Musk Roses. Although this Rose owns Aglaia for parentage on one side, it inherits none of the shy-blooming propensity that this latter exhibits in its early stages. I believe Schneewitchen will be in great demand for massing in quantity, and as a pot Rose it must also be a favourite.—*ROSA.*

FRUIT.

MULBERRY TREES.

We are so exercised by the names of all sorts of new things—conifers, shrubs, Japanese and American—that very often some of the best things are forgotten, and among them the Mulberry, which there does not seem to be the same habit of planting as in old times. Old Mulberry-trees, like old men and women, die, and we do not often see them renewed, nor is it common to see good stocks of them in nurseries. This should not be, for a more beautiful and fertile tree does not exist for the warmer parts of our country, and the fruit, if well saved, is delicious. Among the most beautiful Mulberry-trees we have seen of late are those standing in the kitchen garden at

suddenly cutting away half of the shoots and leaves; this gives the trees such a rude check that it takes half the season for them to recover from it. As different kinds of trees need somewhat different treatment, I will briefly allude to the needs of the most important classes of fruit-trees grown in our gardens—viz.:

APRICOTS.—These are about the most precocious of all our wall-trained trees, both in regard to flowering and wood growth; consequently, need attention early in the season, as they bear fruit freely on spurs. They are usually trained in the fan shape, as this allows of any failing branch (to which the Apricot is especially liable) being removed, and the tree reformed without much difficulty; but it is advisable to have a good lot of young intermediate branches laid in between the main limbs, as they not only bear the finest fruits, but are especially valuable for converting into

shade the fruit to no good purpose. Gooseberries, if trained, need the young growth shortening back to four leaves.

CHERRIES of all the sweet, dessert kinds crop freely on spurs, and are mostly trained on the fan system. The Morello, that bears its finest fruit on the preceding year's wood, must have plenty of the current year's growth retained; but it need not be nailed in or tied until later in the season.

PEACHES AND NECTARINES require, and will pay for, a good deal of attention in the early part of the summer, for once get them started into a clean healthy growth, and little more will be needed; but neglect them for ever so short a period so that the leaves get curled up, blistered, and full of fly, and there will be a season's work to get them clean again, and then without the possibility of thoroughly ripening the current year's wood, and on this the success

Old Mulberry-trees at Glynde Place, Sussex. From a photograph by G. A. Champion.

Glynde in Sussex, which are certainly the most picturesque and tallest we have seen for many a day. We show them in their early spring aspect, when the leaves are just in the budding stage, and one could hardly see a more beautiful group for the centre of a garden.

SUMMER PRUNING OF FRUIT-TREES.

(REPLY TO "G. H. C.")

SUMMER pruning cannot be done all at once if the well-being of the trees is studied, but must be carried out by degrees through the entire growing season, according to the vigour of each tree. No hard-and-fast rules can be laid down. The operator himself must judge as to each tree's special needs, but the worst kind of pruning, and that which cannot be too strongly condemned, is that of letting the trees grow into a tangled mass of breastwood, and then

main branches when any old ones are removed. Pinching back the foreright shoots requires frequent attention.

APPLES need attention directly they have set their fruit, for, if fine fruits are desired, the branches must be thinned out to one or two of the most promising; and the foreright shoots that are not needed for extending the tree should be pinched in when they have made half-a-dozen leaves.

BUSH FRUITS, although not usually summer-pruned, are greatly benefited by it, especially Red and White Currants, that should have the leading shoots cut back to about six leaves, as this not only concentrates the vigour and ensures the thorough ripening of the buds at the base of the current year's wood, but allows the fruit to put on a much richer colour. Raspberries should have all the surplus young canes that spring up at the base removed at once, as they only rob the fruiting shoots and

of Peach culture depends. Directly there is leaf-growth enough to see, look over the trees almost every day, and every leaf that curls up should be picked off at once, and if any trace of black-fly is visible dust with Tobacco-powder, and as soon as the fruit is set ply the syringe or garden-engine freely on them. Disbud by degrees, removing a few of the most prominent shoots that are not required at each time the trees are examined, until only the shoots required for laying in are left. Do not crowd the young wood—it is only a waste of force to lay in two shoots where there is only space for one. Mulch the roots and water freely if dry weather prevails.

PLUMS are almost invariably trained on the fan system, and the principal attention they require is to pinch in the points of the foreright shoots at about six leaves from the base, only leaving the leaders on those required to fill up gaps at full length. Should there be

any shoots getting bare of short fruitful spurs it will be well to train in another at the base, so that the old branch may be removed at the next winter's pruning.

VINES on walls are much neglected; they should be disbudded the same as those under glass, and directly the bunches are visible pinch out the point of the shoot, one joint beyond the bunch, only allowing shoots to extend that are needed for new fruiting canes.

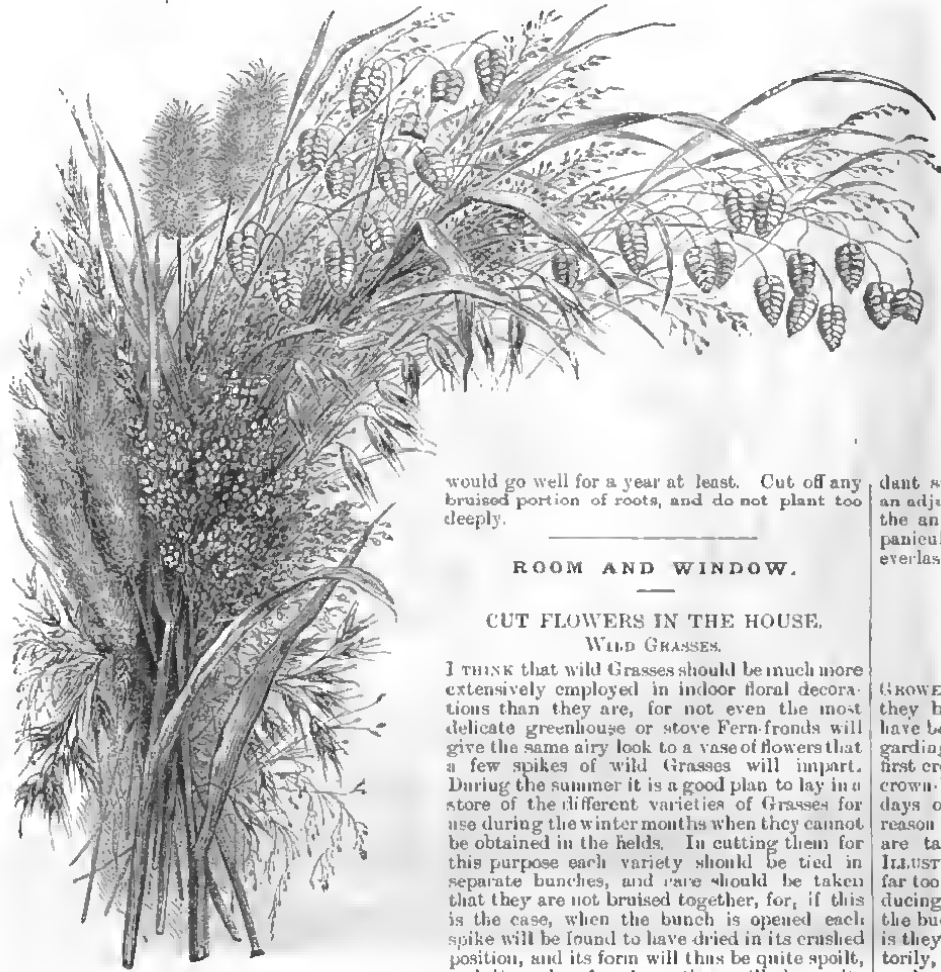

NOTES AND REPLIES.

Lifting Peach-trees and making border (S. J. A.).—It is not safe to commence the lifting of Peach-trees until November, unless those entrusted with the work are men of experience. Some gardeners carry out lifting in October, but, at some-times this is a sunny month, much harm may

using, is the most important item. Lime grit, preferably that obtained from old, demolished buildings, is a necessary addition to the soil. A little burnt ballast or refuse from a garden smother, together with the lime, will suffice, if the soil is of good character, to form a suitable Peach-border. Grossness is an evil to be avoided in Peach-trees, and which is sure to follow in an over-rich border. It is better to feed in after-time, when there is a declining vigour apparent. One important point is firmness of the soil. This cannot be overdone, provided the soil is on the dry side. Raming and treading as the soil is filled in promote short-jointed growth. A great extent of border is not necessary at the outset, and it may be more advantageous to extend the supply of new soil periodically as the roots extend outward. So long as there is ample width for the existing roots to be laid in, all

the green of the other Grasses, flowers, and foliage employed in its decoration. For a trumpet vase the graceful drooping Oat-Grass is best adapted. The common Horse-tail is also not to be passed over, as it, like the Grasses, forms a valuable addition to floral decoration, and may be found growing in moist places in country lanes, or sandbanks by the sea. The accompanying illustration shows some of the best of the Wild Grasses for the purpose of room decoration.

It is chiefly those who recognise the advantage Grasses are in connection with table decoration who grow them. The amateur, who at times is at a loss for some light, fragrant material as an adjunct to his vase of cut flowers, forgets the beauty there is in ornamental Grasses. One has only to try the effect of a few sprays of *Eragrostis elegans* or *Avena sterilis* in a vase of Iceland Poppies, or *Braux maxima*, or *Lagurus ovatus* among Sweet Peas, to be convinced of their utility. The commonest Grasses of the field when rightly used are an aid in many cases to cut flowers, and there are few gardens where those mentioned will not succeed.—TOWNSMAN.

Some Grasses suitable for arranging with cut flowers.

would go well for a year at least. Cut off any bruised portion of roots, and do not plant too deeply.

ROOM AND WINDOW.

CUT FLOWERS IN THE HOUSE.

WILD GRASSES.

I think that wild Grasses should be much more extensively employed in indoor floral decorations than they are, for not even the most delicate greenhouse or stove Fern-fronds will give the same airy look to a vase of flowers that a few spikes of wild Grasses will impart. During the summer it is a good plan to lay in a store of the different varieties of Grasses for use during the winter months when they cannot be obtained in the fields. In cutting them for this purpose each variety should be tied in separate bunches, and care should be taken that they are not bruised together, for, if this is the case, when the bunch is opened each spike will be found to have dried in its crushed position, and its form will thus be quite spoiled, and its value for decoration will be quite destroyed. All Grasses should be dried in an upright position, particularly those of a drooping character. Oats, while still green, are very pretty in large arrangements, especially ears of the Black Oat, which I have but very seldom seen used; this Oat forms a charming contrast to ordinary Grasses and Sedges, and I have constantly used it myself when I have been able to obtain it. The great value of Grasses is, that in addition to giving a light appearance to a vase, a large plume of handsome Grasses and Sedges enables one to dispense with many flowers. To some this may be no object, but to many it must be a matter of consideration. My attention has been directed to the usefulness of the bloom of the Ribbon Grass for mingling with flowers, and I can bear testimony to its utility for this purpose. The bloom has a silver-like lustre in some stages of its growth, whilst in others it assumes a rosy-pink tint, which is equally pretty. In the trumpet of a March vase, which has been dressed with pink and white flowers, a few spikes of the Ribbon Grass bloom help to carry up the colour with charming effect into

Gypsophilas in the house.

Gypsophila elegans is an annual that ought to be cultivated by all who delight in cut flowers for home decoration, as the miniature white blossoms are very beautiful when arranged with vases of Irises, Poppies, Sweet Peas, and, indeed, with almost any flowers. It may be sown even now in the borders with a certainty of coming in useful in about a month's time. Those who have not hitherto grown the perennial form, *Gypsophila paniculata*, should not forget to procure plants this autumn, as, when once established, it provides one with an abundant supply of foamy flowers, invaluable as an adjunct to a vase of blossoms, and well the annual form. The blooms of *Gypsophila paniculata* keep for months when cut, being everlasting.—LEAUCREST.

CHRYSANTHEMUMS.

SEASONABLE HINTS.

GROWERS of large blooms, no matter whether they be wanted for exhibition or otherwise, have been anxious during the last few days regarding the question of the development of the first crown-buds on their plants. If the first crown-buds were developed during the closing days of June or early July, there is every reason for being pleased with the course events are taking. Many readers of GARDENING ILLUSTRATED may not be aware that it is yet far too early to think of retaining buds for producing exhibition blooms in November. When the buds retained at this time the probability is they would ultimately fail to open satisfactorily, and would also come with hard centres or else develop into hen-and-chicken buds. A their best the resulting flowers would most likely be quite out of character, and their colour very poor and washy. For this reason the first crown-buds which have so far developed should be pinched out, and the strongest individual shoot of those surrounding the bud be grown on with all possible vigour. These same shoots will quickly attain desirable proportions, and by the third week in August or near to that time the long-looked-for second crown-buds should make their appearance. Buds developing at the period just mentioned as a rule give very handsome flowers. They open kindly, and the colour is good, and the flowers are also large and of good form. This now brings us to a period in the history of some Chrysanthemum plants where no first crown-bud has developed, and there may be those who are in doubt how to proceed under the circumstances. Plants which have not yet developed the first crown-bud should have the points of their shoots pinched out without a day's delay. This manipulation of the shoot will induce them to break out into fresh growths in the axils of the leaves immediately

be done should the trees not be in a good state at the roots, and not carefully nursed afterwards. In November the leaves are falling naturally, which is a period when some deciduous trees form new roots, and by moving them at that time they become somewhat established and ready for starting strongly into growth in spring. A semi-circular trench should be dug at a distance governed by the age of the tree and extent of roots of the tree, these being preserved as much as possible from injury. The digging fork is the better implement for this work. A distance of from 2½ feet to 3 feet from the stem should be allowed in opening a trench, and as deeply as roots are found. As soon as these are well raised, protect them with a covering of some kind to exclude air and to keep them moist to prevent their extremities shrivelling. The border need only be of simple construction: good loamy turf of a calcareous nature—put early so that the Grasses destroyed prior to

below where the pinching took place. In a little while select the strongest shoot on each stem, rubbing out all the weaker ones, growing on the one retained with all vigour. High culture is essential to success, and from this period until the flowers are fully opened care must be given to the plants. Keep the shoots carefully tied out, as every endeavour must be made to ripen the wood. Without this important factor in the culture of the Chrysanthemum it is impossible to attain success. Watering is another important item in successful culture, a few hours' neglect sometimes causing a failure. Manure-water need not be given until the pots are pretty well filled with roots. In all cases when watering it is well to go through the plants a second time. A single application of water is really very superficial, and in hot and trying weather its evil effects may be traced in the plants themselves. Always thoroughly moisten the ball of soil. Keep the surface soil free from weeds, as they may cause much inconvenience later. Keep green fly and black fly under by a dusting with Tobacco-powder occasionally. Water overhead with clear water from a fine-rosed can in the evening of hot days. E. G.

— Now that the warm weather has come in earnest growers of Chrysanthemums will have to keep the water-pot going at least twice a day, and where a number of plants is grown this means additional work. Taking everything into consideration, however, the extra labour expended well repays itself in the end in the shape of robust plants and plenty of bloom. With good attention, the growth of the plants is very rapid now, and the shoots, as they grow, must be tied to the stakes, or else grievous havoc will result should a gale of wind come unexpectedly. No plant should be stopped or pinched later than the third week in June, and encouragement should be given to promote healthy growth by giving a little scot water about once a fortnight, on no account letting the plants have any other stimulant, which at this season would do more harm than good by promoting rank, useless growth. I have always found it pay well whenever possible to give the plants plenty of room in their summer quarters. Top-dressing is very beneficial, but is not to be recommended, nor is it necessary when the plants are merely required for decoration. It is essential, however, from an exhibitor's point of view. —D. G. McI., B. of H., N. B.

Fixing "sports."—Many amateurs and others may have an opportunity when the season comes round of fixing a sport, and a simple means of doing so I will now describe. If a certain plant should throw a bloom of a different hue on one of its stems, and the said bloom be of good shape and form, preparation should be made to fix the sport. In order to do so, loose the stem from which the sport issues from the stake, cut off all the others close to the soil, reserving only this one. Prepare a shallow box about 3 feet long, put a layer of rough soil in the bottom for drainage, filling up with nice light sandy soil. Peg down thereon the sported stem, still keeping the roots intact in the pot, and finally scatter a little sharp sand over each joint, damping all down through a fine rose. The soil must be kept moderately moist and preferably in a little heat. Shoots will soon be encouraged to spring from the axils of the leaves, which should be taken off with a sharp knife when about 1½ inches long and inserted singly in thumb pots of sandy soil. They may be rooted now in gentle heat, and afterwards grown on in the usual manner. It is advisable to allow them to grow naturally from the beginning. When the sports bloom they often go back to the original colour, but should the sport come true it may be said to be fixed—for the time being, at any rate. I have seen instances of sports going back to their original colour after three years. If after such a period elapses and the sport continues true, and is thought to be an improvement on existing varieties, blooms should be sent to any of the meetings of our Chrysanthemum societies, along with description, height, habit, etc., when the sport will be judged on its merits. —D. G. McI., B. of H., N. B.

TREES AND SHRUBS.

THE MEDITERRANEAN HEATH.

ALL the hardy Heaths are very beautiful plants as grown on suitable soils, and this species (*E. mediterranea*) is one of the best and most showy. It is a native of western France, Spain, and the Mediterranean region, but is a free and luxuriant grower on non-lime containing soils elsewhere in Europe as a garden plant. A very distinct form of this plant is found wild in Ireland, in Galway and Mayo, in boggy heaths, but not elsewhere in Britain. The type plant, as shown in our illustration, attains a height of 6 feet to 8 feet, or even more in sheltered positions, flowering profusely in April and May. The Irish plant is more dwarf in habit, rarely exceeding 3 feet in height, and having a more virgate habit of growth, with more grey or glaucous leafage, and the flowering growths are shorter and the flowers paler in colour. The late Prof. Boswell Syme considered the Irish plant to be a distinct species, and called it *E. hibernica*, but

order succeed. They also grow on loamy soils on the granite and sandstone formations, in beds or borders enriched with leaf-mould and cow-manure, on a moist bottom. As grouped with other kinds near natural rocks they are very handsome. Other good kinds are *E. carnea*, white and reddish-purple; *E. stricta*, rose-coloured; *E. vagans*, white, or rose-purple forms; and *E. hybrida*, one of the earliest and best of the dwarf kinds, said to be a cross between *E. carnea* and *E. mediterranea*. The largest and most fragrant of all the Heaths is *E. arborea*, from Greece, where, as at Mount Athos, it grows 20 feet to 30 feet in height. In Co. Wicklow this Tree-Heath of Eastern Europe is often very sweet and beautiful, growing from 6 feet to 12 feet high, and in April, when covered with myriads of white, almond-scented flowers, it is a great attraction to the bees. The celebrated honey of Mount Hymettus is said to obtain its delicious flavour from this plant, just as the Heather honey of Scotland and the north of England is valued for a similar reason. Our illustration is from a photograph taken by Mr. Geo. Farmer,

Erika mediterranea in the Botanic Gardens, Glasnevin, Dublin.

Hooker calls it *E. mediterranea* v. *hibernica*. According to Moore, in the "Cybele Hibernica," it is very local, being found on boggy mountain heaths near the coast line in Mayo and Galway, flowering in April. It was discovered at Urrisbeg by Dr. J. T. Mackay in 1830, and since that date it has been found in other places by various collectors, as on the western declivity of Urrisbeg Mountain, near Roundstone, Connemara; on Mweelrea Mountain, at the mouth of Killery Harbour, Co. Mayo; at Mulraun, opposite Achill Island; on the north side of Clew Bay, at Curraun Achill, and Burreishool Lake, all along Achill Sound on the shore of the mainland opposite Achill Island, and thence near the shore as far as the north end of the Carrowmore Lake, in Ennis, the plant here being a dwarf variety, with flowers of a deeper purple than in the Urrisbeg plant.

Both the Mediterranean and the Irish forms of this beautiful Heath are very hardy and long-lived on sandy peat or light boggy soils, and thrive best in sheltered places wherever Rhododendron, hardy Azaleas, Pernettyas, and other lime-hating plants of the

in May last, in the Royal Botanical Gardens at Glasnevin, near Dublin. F. W. E.

Honeysuckle not flowering.—Will you kindly tell me what would be the best thing to do with a Honeysuckle that for the last three years has not flowered, but is covered with blight? It is quite ten years old, and used to be a mass of bloom very early in the spring. It is trained up part of the house, S.E. aspect. We have manured the roots and syringed at times. Had we better cut it down? —AUGUS THOMSON.

[You had best thin it well out, laying in as much of the young wood as you can, and then syringe freely with paraffin-emulsion.]

Ceanothus rigidus.—The number of outdoor shrubs with blue flowers is very limited, being principally confined to the different kinds of *Ceanothus*, and as this is the first of the genus to unfold its blossoms, it is for this reason valuable. This *Ceanothus* is not so hardy as some of the others, but is well worth the protection of a wall. It forms a neat, freely-branched bush, thickly clothed with small deep green leaves, while the flowers are of a deep purple-blue. This *Ceanothus* is a native of California, from whence it was introduced in 1843. It is often employed for covering under the shape of neat

bushes profusely bloomed, and in this way is widely removed in general appearance from the whole of its associates. All the different species of *Ceanothus* are very pretty shrubs, while the numerous garden varieties claiming parentage from *C. azureus* and *C. americanus* yield several distinct shades of colour.

VEGETABLES.

EARLY CABBAGES.

Now is the time to think of the next spring supply if this useful vegetable is required in quantity. To get an early supply, the time of sowing in most cases should depend upon the district and the soils in which the Cabbages are grown. In late districts the last week in July is none too early to sow. The chief point is getting sturdy plants that will stand the winter. To obtain these I advise pricking out as soon as the plants are large enough to handle. I have often seen large breadths of this favourite spring vegetable with scarcely a plant left at the end of February. I do not see how it can be otherwise when the plants are left crowded in a small seed-bed till, perhaps, late in October before planting-out takes place. If, by chance, a mild winter should favour them, they invariably succumb to the fierce blasts of our March winds, which we rarely ever escape. I should, therefore, advise two sowings, one at this date and another two or three weeks later. I find that the seedlings are much better when pricked out on land that has been manured for a previous crop, as it given fresh manure the growth is too quick for the winter plants. For spring growing quick growth is necessary, as the plants only remain a short time on the ground; but it is different when a short sturdy growth is required. The ground, before pricking off, should also be made rather firm. I think the best plants for early spring use are the small kinds. I have observed that these suffer much less than the larger varieties, and in private places I consider a large, coarse Cabbage of no use. Many gardeners have their own special varieties, and I certainly advise them to keep to them when they have secured a good early kind. Of late years several good kinds have been sent out, but some of them are old favourites under new names. Still, a step in the right direction has taken place, many of the large coarse kinds grown a few years ago having been discarded for the small compact varieties. *Ellam's Dwarf Early* is a good kind for sowing at this date, followed by a later sowing, in three weeks, of the old true *Nonpareil*, thus forming a succession. An excellent Cabbage to succeed the *Nonpareil* is the *Early Dutch Drumhead*. This is handsome and productive, and one of the best of the early round-headed Cabbages. When strong, sturdy plants are secured for planting in their permanent quarters early in September in ground deeply dug and the plants thickly planted, say, 12 inches apart from plant to plant, and 2 feet in the rows—I advise 2 feet, as it allows plenty of soil to form a ridge for protection against east winds—every other plant may be used very early in spring, and thus allow the remaining ones room. I do not advise too much manure, but prefer it deeply dug in, so that the plants can obtain assistance from it at the time most required—namely, when starting into growth in early spring. If on the surface, it only excites a premature growth likely to be destroyed by the first frost that comes. W.

A good Broccoli.—Where a large and continuous supply of Broccoli has to be maintained, it behoves those responsible to select suitable varieties. There has been this past winter such weather that only the hardiest of Broccoli could survive the ordeal. There have been, it must be said, worse winters, and effects more disastrous than in the past one, but there has been a great thinning down of the beds which, without a goodly number of plants and an assortment of hardy varieties, would have told seriously on the daily demands. One that has proved itself absolutely the most hardy is *Continuity*. This has survived almost to a plant, and, while it possesses this great resisting power against frost and cold, it is perhaps the purest coloured of the *Broccoli*.

young state it is almost as white as an early Cauliflower, the curl very compact, and this well protected by foliage. Many Broccolis, when matured, expose the flower to every morning frost and sun ray, making them liable to damage from both. Not so *Continuity*. Its name is derived apparently from the continuous nature of its supply, which extends over a long period. This can be strongly recommended for May cutting, and, if seeds are sown by the end of the month of May, there will be ample time. My present stock was planted on an old Strawberry bed, where, naturally, the soil was firm, a point of much importance in winter Broccoli culture.—R.

GARDEN PESTS AND FRIENDS.

The spotted ladybird.—Enclosed are specimens of insect which appears to feed on the aphid infesting Apple and Plum-trees. Would you kindly tell me the name, and if I am right in supposing it preys on the aphides?—N. OSUDA.

[The insects you sent are the grubs of the common two-spotted ladybird (*Coccinella bipunctata*). They feed, as you imagine, on the aphides infesting your fruit-trees, and destroy large numbers of them. Ladybirds and their grubs are most useful insects in gardens, and should be encouraged in every way.—G. S. S.]

Geranium leaves, fungus on.—I am sending some leaves of Geranium which seem affected by a blight or insect, and also two Begonia leaves which may be suffering similarly. The Geraniums are very tall ones for a wall, and have been out three weeks.—M. N.

[Your Geranium and Begonia leaves are attacked by a fungus belonging to the genus *Cercospora*. Pick off the leaves that are badly attacked and then spray the plants with Bordeaux mixture, and see that there is due ventilation and that the plants are not kept too damp. The spraying should be done every week or ten days while the disease continues to spread.—G. S. S.]

Romneya leaves, insects on.—I shall be much obliged if you will kindly tell me what is the name of the insect on the Romneya leaves enclosed, and the best means of destroying it without injuring the plants? Last year every flower was spoiled by these caterpillars, and a spraying of weak insecticide did more damage to the buds than to the insects.—H. A.

[The caterpillars on your Romneya leaves are those of a small moth belonging to the family *Geometridae*, but I cannot give you their name more definitely, as they are apparently in such a juvenile condition. The most certain way of destroying the caterpillars is picking them off by hand, but it is a tedious process. Spraying with a weak insecticide should not do harm. It should be applied with a syringe with a spray nozzle, and should not be used when the plant is in flower unless the blooms can in some way be protected. Watch the plant in the spring, and kill any moths that you see flying about or settling on it. The chrysalides are probably formed in the soil, in which case it would be well to remove about 1½ inches of the soil in the winter.—G. S. S.]

Fungus on Strawberry leaves (John Hobbs).—The substance on your Strawberry leaves is a fungus, one of the "slime fungi," known as *Spumaria alba*. This fungus will not injure your plants in any way, though when it decays it may spoil some of the fruit. It appears to be very common this year. These fungi are very curious. At a certain period of their existence they are in a somewhat jelly-like condition, and are then able to crawl along the moist earth and up anything they may come across. The jelly-like mass then assumes the form in which you found it, and is then practically a mass of spores. These spores when they reach the ground after a time burst, and a little gelatinous body is produced, which has the power of movement on and in moist earth. Frequently many of these join together, and form the jelly-like mass already mentioned. Pick off and burn as many of the masses of fungus as you can find.—G. S. S.

Green-fly.—What is the origin of green-fly, and what are its various stages? I have a new greenhouse, and I find them on Roses which, apparently, were clean when planted.—YEWCLIFF.

[Green-fly, like all other insects, undergoes certain transformations, but some of these are not so well marked as in the case of most insects. The females lay eggs in the autumn, which hatch in the spring. The insects that are produced are all, or nearly all, females.

These do not lay eggs, but produce live young ones, and at a most astonishing rate. I have watched one give birth to three within an hour, and these, when three days old, will begin to breed at the same rate, so that, though your Rose was apparently clean when planted, if it had only one green-fly on it or one egg, it might soon become covered. During the spring and autumn many of the green-fly become winged, which is evidently a provision of nature to enable the aphides to found new colonies on other plants, so as to ensure the preservation of the species. As a rule, the true sexes do not appear until the autumn, when the females lay eggs, that, as before mentioned, do not hatch until the following spring.—G. S. S.]

Insects on Apple-trees.—Will you kindly tell me what species of insect pest this is on the enclosed Apple leaves? There were a brilliant show of blossom, and promise of a very heavy fruit crop, then came the late frosts and high east winds of May last, and those insects appeared. Tell me whether they or the weather are responsible for the destruction of the fruit? The brown, shrivelled flowers still adhere to the trees, but drop at a touch. Should the trees be treated in any way to prevent, if possible, a recurrence of these pests next year.—MAREL.

[The leaves of your Apple tree are infested with the Apple aphid (*Aphis mali*). The blossoms are so dead and shrivelled that I cannot say what has injured them, but I should think the weather was probably responsible for the mischief. I should, if the size and position of the tree will admit, pick off all the dead flowers and the leaves that have been much injured, and then spray the tree with a solution of paraffin emulsion. When the leaves fall, collect and burn them. In the course of the winter give the tree a good spraying with a caustic alkali wash. Aphides of various kinds seem unusually abundant this year, which seems strange, as one would have thought that the cold, wet spring would have been detrimental to them.—G. S. S.]

Mildew on Roses.—What is the cause? I have a Rose planted outside the greenhouse with one branch outside and one branch inside the house; the foliage is mildewed in both cases, but more so inside. The Rose-tree planted inside the same house does not suffer from mildew.—YEWCLIFF.

[The spores of the mildew are probably floating everywhere in the air and settling on everything. Wherever a spore finds itself in a congenial situation it germinates and begins to grow, and the more suitable its position and surroundings the faster it increases; the less healthy a plant is, like human beings, the more liable it is to be attacked by disease. The Rose in your house is evidently in a more healthy condition than the one outside, and the mildew finds that out, or, rather, the spores do not germinate on the healthier plant. From the fact that both the outside and inside branches of the outdoor plant are mildewed shows that either the soil or the atmosphere in the latter case does not suit the Rose so well as, the same circumstances indoors; but perhaps both are not of the same kind, and it should always be remembered that some kinds of Roses are more liable to be attacked by mildew than others.—G. S. S.]

Insects on Black Currant-bushes.—The enclosed shoots are off my Black Currant-bushes, which, having dropped all their fruit, are now losing their leaves as well. Will you be kind enough to say what is the matter with them? There has been a great deal of Black Currant disease in the neighbourhood, and this spring all the buds on these trees which were affected were pulled off and burnt. Is this a further development of it, or something else?—R. A. ALLISON.

[Your Black Currant bushes are attacked by one of the aphides, probably *Myzus ribis*. I was unable to find any live ones, as they had all been killed by the grubs of the Two-spotted Ladybird and the grubs of one of the "Horseradish flies" belonging to the genus *Syrphus*, of which there were several specimens among the shoots. The former are small black or slate-coloured insects spotted with yellow, and about 3-10 of an inch in length, and are very active; the latter are yellowish plump grubs about ½ inch long, tapering very much towards the tail. A sharp look-out should be kept for these aphides in the spring, and as soon as any of them are noticed the under sides of the leaves should be sprayed with a solution of paraffin emulsion or some other insecticide in which there is a certain amount of soft soap. If the aphides are allowed to curl up the leaves before the spraying takes place it will be impossible to make the insecticide reach them.

The only thing then to do is to pick off the leaves and burn them. In the course of the winter it would be well to spray the bushes with a caustic alkali wash. This pest has nothing to do with the "Currant gall mite," which is the cause of the swollen buds. — G. S. S.]

GARDEN WORK.

Conservatory.—The early-flowering Pelargoniums which have been ripened by exposure outside may now be cut down and the cuttings put in. They will strike outside on a coal-ash-bed, dibbled firmly into sandy soil round the sides of 5 inch pots. *Hydangea paniculata grandiflora* is now finely in bloom in 6-inch pots. After flowering the plants may be plunged or planted out. To keep the plants compact rather than hard pruning is necessary when the plants are lifted again in autumn. The plants should be brought on quietly, not forced much. The Scarborough Lily is one of the brightest and most useful of the Amaryllis family. Being an evergreen, it does not require drying completely off, but after growth is finished less water will be required. The best way of giving the rest which is needful to produce many flower spikes is to turn the plants out into a cold-frame, with the lights off after the first week, giving water enough to keep the foliage fresh and green. By the end of September the flower-spikes will be showing, when they may be taken indoors. When I first grew this plant many years ago it was commonly treated as a stove plant, but it does better under cool treatment, with a couple of months' exposure in summer. Cuttings of *Salvia grandiflora* rooted now, pinched twice to make them bushy, and grown cool, will make nice plants in 5-inch and 6-inch pots. The early-struck plants may be shifted on into 3-inch and 8-inch pots. Older plants which have been cut back and planted out in an open, sunny position will make very large specimens. Double white Primulas that were mulched with Cocoa-fibre or Moss will now be in condition for cutting up. Start them in small pots in equal parts of loam, peat, and leaf-mould, with plenty of sharp sand to keep the soil open and sweet. Place in a frame and keep close and shaded for a time till roots are forming, and water when dry only. The peat in the compost will help to retain moisture, and much watering only sours the soil. The *Stachys* are a very useful family now. *S. profusa* and *S. Holfordii* are two of the most useful; both will make good specimens and come in useful at the summer exhibitions when well done. *Trachelium coeruleum* is a useful blue-flowered umbelliferous plant, easily raised from seeds and cuttings.

Stove.—Ventilate this house with more freedom now to ripen growth. The nights and days are as warm as they are likely to be, and soft, warm air circulating among stove plants will have a beneficial effect. By way of experiment we have in years gone by turned various stove plants outside, especially such hard-wooded plants as *Gardenias*, *Franciscas*, etc., for a couple of months with considerable advantage as regards flowers the next winter, and this treatment has a hardening, cleansing effect. The stove *Hibiscuses* are benefited from an outing for a month. The *Eucharis* family flowers all the better for a rest in a lower temperature, but should not be dried off altogether, as it is a true evergreen. We have completed our stock of *Poinsettias*, and the earliest rooted plants are in a cool-pit, lightly shaded from the hot sun in the middle of the day, with a notch of air on at the back. This ensures sturdy growth, and the leaves under such treatment will not fall prematurely. Liquid-manure may be given to plants which have filled the pots with roots, but it should be in a clear, weak state. There are bright bugs among the Clerodendrons, such as *C. fallax* and *squamata*, which might be added to the collection with advantage.

Orchard-house.—Use the syringa freely now, and see that the roots of the trees, whether grown in pots or planted out, are kept moist. This is the time when the red-spider makes its appearance if a tree has received a check from any cause, or if there is a deficiency

of moisture anywhere. Liquid-manure may be given freely now to the late varieties. Early sorts, even where no fire has been used, will be ripe or ripening, and a deluge of water at such times will spoil the flavour. To obtain flavour there must also be very free ventilation night and day. The night ventilation will be less in quantity, but the circulation must be kept up. If the potted trees are at all crowded, it will be possible to take out late Plums and plunge them outside, and the trees from which the fruit has been gathered, such as the Early Rivers' Nectarine, will be better outside.

The Rose-house.—If I were now building a house for Roses, the roof should be movable, and should now be taken off and the plants exposed to ripen the wood. One does not want many Roses under glass when there is plenty outside; besides, the plants under glass should be resting now for the work in winter. All plants in pots should be plunged outside, but not forgotten or neglected.

Late Melons in frame.—Keep the growth thin, and if top-dressing is required, use yellow loam, and mix a little bone-meal with it. The loam should be adhesive, not sandy. To do Melons well they must have a firm root run. Should canker make its appearance, attack it at once with quicklime, changing it from time to time as required until the disease is killed. The nights have been cold lately, and mats are still used, but must be removed early in the morning, and a crack of air given along the back. Melons require less water when planted in heavy loam, but enough should be given for healthy growth, and a stimulant should be included when the fruits are swelling. Sprinkle every bright day when closing.

Window gardening.—Cuttings of most of the plants grown in windows will strike now outside in a shady place, except Pelargoniums, which seem to enjoy the sunshine. Use rather small pots and sandy soil made firm, with a layer of sand on the top. The principal reason why so many fail with Heaths and Azaleas is, they are forgotten and neglected after flowering. This is the time when extra care should be given, especially as regards watering and damping the foliage. The plants now are better outside, but should not be left altogether to the mercy of the wind, or dependent upon showers for the water supply.

Outdoor garden.—The hoe should be used freely among growing plants. If it should be necessary to water, stir up the surface next morning with the hoe. This will check evaporation. The best time to water is in the evening, between 5 o'clock and 8 o'clock. Mulch all strong-rooting things, such as Hollyhocks, Dahlias, and Phloxes, with manure. Moss-litter manure is suitable for mulching, as it lies close and is not so untidy looking as straw-litter. Give liquid-manure to Tea and other Roses growing on elevated beds and borders. One of the finest masses of Tea Roses I saw last season was growing on a sloping bank facing south. The ground had been well prepared, and the plants were well nourished. It is the preparation of the ground in the first place and giving proper surface nourishment afterwards when the buds are visible that bring success. There is a dearth of blossoms among shrubs now in the dry eastern counties, where the soil is not suitable for the *Rhododendron* family, but there are compensations in the Rambler Roses and Honeysuckles when planted freely. Peonies, too, are lovely, and all the hardy flowers thrive when properly treated; but there is no manure so suitable for a dry district as that from the cow and the pig. Iceland Poppies are making a brave show now.

Fruit garden.—Raspberries look promising, and will pay for a mulch of manure. There are insects on Red Currants, which should be promptly dealt with by pruning back and thinning the summer shoots, following up with a wash of soft-soap, 2 oz. or so to the gallon, applied somewhat forcibly with the syringe. Follow up the spraying of fruit-trees with an insecticide. There are suitable things for washes without using arsenic, though the latter is safe enough in careful hands; but a Petroleum of Quassia wash will answer the same purpose. This has been a peculiar sea-

son as regards the weather. For many weeks we were pierced through with the east wind; now we are being roasted with a tropical sun, which is drinking up all the moisture from the soil, and when mulch is not used, and the hoe remains idle, things—even hardy fruits—must fall, and they are falling in considerable numbers in some gardens. Summer pruning of wall and other trees which are more or less trained may begin now. Do the top of the trees first, and leave from four to five perfect leaves on the spur. Where Plums are much infested with insects the summer pruning will clear off many, and some of the curled leaves may be removed also. Try the effect of Tobacco-powder on those trees with curled foliage; it is more penetrating than a wash.

Vegetable garden.—As the early Potatoes are cleared off, give a dressing of soot and superphosphate. Hoe it in deeply, and the land will come in for Turnips, Celery, or Strawberries. In the case of Celery the top-dressing and hoeing may be omitted; but Celeries, which does not require trenches, may be planted on the top-dressed ground in rows 2 feet apart. There is generally a demand for Globe Artichokes at this season and later, and to ensure well-developed heads the plants must be well nourished. To make sure of useful heads all the summer always have young plants coming on, and feed them with rich mulchings and liquid-manure. Sow Radishes on the north side of a wall. These north borders will be valuable now if this hot weather continues for Caulflower and salad plants. It will be wise to sow a good brown Cos Lettuce now with the green-leaved kinds. The brown-leaved kinds are hardy and reliable. Tom Thumb Cabbage Lettuce is an old favourite with many. A sprinkling of nitrate of soda will help the Onion crop. If Mushroom-beds are made up now, they should occupy a position in a shady spot on the north side of a building or wall. Mulch Tomatoes, and keep the main stems trained and free from side growths. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 21st.—Sowed Brown Cos and Tom Thumb Cabbage Lettuces. Shifted Cinerarias from the boxes where first pricked off to 3½-inch pots, the soil used being two-thirds best loam and one-third very old manure and sand. The pots were well drained. Thinned the young wood of Gooseberries and Red Currants to let in the sunshine. The bottom leaves of Tomatoes are thinned and shortened as the fruit colours, but plenty of foliage is left on to carry on the work of the plants. Sowed Eillam's Early Cabbage.

July 22nd.—The earliest Celery is being blanched with paper wrappings. This permits of water being given for some time longer. The final blanching will be done by earthing up, but the paper begins the forcing by excluding the light. We are busy securing Strawberry runners for forcing. Royal Sovereign is the favourite for early work. In addition to mulching Hollyhocks, Phloxes, Sweet Peas, and other things requiring it, as far as the supply of manure goes, liquid-manure is given.

July 23rd.—A little earth has been hoed down round Leeks planted in trenches, and liquid-manure is given occasionally. Hoeing and thinning Turnips. Late Peas have been mulched with good manure. We are now summer pruning wall-trees and espaliers, but not cutting very hard back. We want to let in air and sunshine without causing much late growth. In the case of trees which are making much growth upwards, the bottoms of the trees are left unpruned.

July 24th.—Removed the seed-pods from Canterbury Bells and Antirrhinums, both of which have been very bright in the borders. The last of the hard-wooded greenhouse plants have been placed outside. Scarborough Lilies have been placed in a cold-frame with the lights off. Cyclamens which are now in 5-inch pots are freely ventilated. On calm nights the lights are drawn off to harden and dwarf the

foliage. Made a last sowing of Bridesley and Horn Carrots.

July 23th.—Thinned the shoots of Dahlias, and, in addition to the central stake, four other stakes are placed round each plant to keep open and support the main shoots. Fruits of various kinds have been netted up to protect from birds, and a few bottles half filled with treacle and beer have been hung up on walls to attract stray wasps. Put in cuttings of choice Links under handlights in the shade.

July 24th.—A second look round has been given to choice dessert Pears to thin off a few more fruits where crowded. Butted a few standard Briers where the bark is ready. Faded flowers are removed from Roses frequently. The borders of conservatory in which climbers are growing are kept moist. Roses in pots which have done flowering have been plunged outside.

Wire hurdles for Peas.—The remarks of "Y." show both their advantages as well as their disadvantages, for it becomes patent to all gardeners that the wire hurdle possesses both. As "Y." says, the advantage comes in where Pea-sticks are difficult to procure, and which it often is near towns and in districts where there are no woods which have their undergrowth cut periodically. Even where there are woods there is often such a demand for Pea-sticks that the supply does not meet the demand. This, in fact, happened last year in my own case, and would each year, if a sufficient stock were not procured early in the season. There are an expense and a proportion of labour connected with sticks which are felt in spring time, but Peas seem to do better when they have stakes provided, and, though costly in the first instance, are useful after as firewood. The advantages of hurdles are that they will last almost a lifetime with careful use. They can be stored away when not in use in any dry place. It is better that they be kept dry, and, if possible, painted, as this not only gives them a better appearance, but prevents rust. They do not afford the Peas the same shelter and protection during early spring as do sticks, nor do they lend an aspect to the garden that can be claimed desirable; at the same time, where sticks are difficult to procure, these overcome the attendant worry once and for all.—W. S.

BIRDS.

Death of grey Parrot (E. Sic).—This bird died in a fit of epilepsy, to which Parrots are rather subject. This trouble is often brought about through the derangement of the digestive organs in consequence of unsuitable diet, while sudden alarm is a frequent cause in a bird predisposed to an attack. In his "Diseases of Cage Birds," Dr. Greene says the first thing to be done when a bird falls down in a fit of epilepsy is to put it in some soft, secure place where it will not injure itself during its convulsive struggles, but, if none be at hand, it is well to wrap it up in a towel and hold it carefully but firmly in the hand, care being taken to avoid the beak, as an epileptic Parrot may bite severely. Before the fit, and while the bird is in the preliminary stage of restlessness that often precedes the attack, a sedative may be administered with advantage, and impending fits may be diverted by a dose of from 1 grain to 5 grains of bromide of potassium, dissolved in a little syrup; and this may be continued once a day for a couple of days. Care must be taken to suitably regulate the diet, to see that the bird is not unnecessarily alarmed, and is not exposed to insidious surroundings.—S. S. G.

Canary ailing (Miss R. Grosvener).—The irritable condition of the skin, causing the bird to peck itself, may arise from indigestion or from the presence of insect parasites in the cage. You appear, however, to feed judiciously, although you may add a little Lettuce-see to the diet, this acting as a mild purgative helps to cool the system. You would also find a piece of cuttle-fish bone placed between the wires of the cage for the bird to peck at of great service in keeping it in health. A few drops of Parrish's chemical food daily in the drinking water would assist in the same way of

the feathers, as this excellent preparation contains all the elements necessary for the elaboration of new plumage. But you should first of all make sure that there are no insects in the cage. Should you find any indications of the presence of these pests, the cage must be scalded or baked, and then well painted internally with paraffin, while the bird should be dusted under the feathers with Pyrethrum-powder. A metal cage is much less liable to become infested by parasites than a wooden one. The presence of these pests may be ascertained if a white cloth be placed upon the cage at night and examined in the morning.—S. S. G.

LAW AND CUSTOM.

Giving up garden.—I am engaged at 15s. a week, with cottage and garden bound, but no contract for any particular notice to leave. I have received a month's notice to determine my service. My garden is well planted. When I leave, on the determination of my service, can I claim for the produce?—J. B.

[It is very doubtful whether you can claim under the Allotments and Cottage Gardens Compensation for Crops Act any compensation for the crops growing in your garden, but you may claim compensation for the labour of planting and for the cost of the seed, etc., and, if I were you, I should apply to the justices to determine the compensation under the above Act if your employer refuses to give you any.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in **GARDENING** free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of **GARDENING**, 17, Furnival Street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as **GARDENING** has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received many queries on this subject, but we are sorry to find that in many cases no trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Woodlice (Anziano).—Woodlice generally are found at the base of a wall or in other positions, and may be killed by pouring boiling water over them. They may also be trapped by laying bricks, tiles, or pieces of slate or boards near their haunts, which they will creep under and may then be destroyed.

Rose Dr. Rouges (Anon).—Many prefer this Rose to the ideal. Certainly the fine branches shown at the Temple recently were of a most attractive colour—rich red, shaded with copper-yellow. The form is quaint, sometimes pointed like a Cactus Dahlia. This Rose is well known as a half-climber, and, of course, succeeds well as a standard, as do all these half-climbers.

Raising Hardy Cyclamens (H. T.).—These are best raised from seed sown as soon as the seed is ripe in well drained pots or pans of light soil. Cover the soil after sowing with a little Moss to ensure uniform dampness, and place in a frame. As soon as the seedlings begin to appear gradually remove the Moss. When the first leaf is developed they should be transplanted about 1 inch apart to seed pans filled with light, rich soil, and encouraged to grow as long as possible, giving the shelter of a cold-frame, but always allowing abundance of air. When the leaves have fallen in the following summer they may be planted out or potted, as the case may be.

Zonal Pelargonium for winter (B. C. R.).—If you have any old plants of Vesuvius that have been recently cut back they will give the best results; failing these, good strong young plants will do. Repot them out once into 5-inch or 6-inch pots in good loamy soil, and when started into growth again plunge them out-of-doors in ash in a very sunny place. Give water moderately, and pick off all flower-buds as soon as they can be seen up to the end of September. Early in October (sooner if cold weather) take them indoors, and if placed in a sunny window of a warm room and freely watered with a little liquid-manure now and then they will bloom well for some time.

Planting Roses (Over 20 Years' Subscriber, Belfast).—The Roses may be planted as near the wall as you choose without, of course, disturbing the footings in any way. The item is not important in itself so long as the plants are trained against the wall. They are better than if a current of air be permitted along the back. You may, therefore, drive your wooden plugs nearly home, and with every advantage to the plants, so long as sufficient room is left for tying. In your selection of Roses for the

house, *Niphetos* is good and *Maréchal Niel* unique, though we would plant *Pere de Mars* in preference where a long supply is required. For your last one, *Reine Marie Henriette*, we should substitute *Bridesmaid*, an exquisitely-formed Rose, and beautiful in every way.

Rose Pink Roamer (F. L.).—This pretty Rose about which you inquire, is well named. It is indeed a roamer, making rapid growth in a season, and when planted so that it can run over roots and branches of dead trees, the lovely mass of blossom has no equal among Rambler Roses. The flowers are perfectly single, and of an intense crimson-pink in the younger stage, changing to paler pink, with clear white centre, as they develop. It possesses the true Dog Rose fragrance, but is not so powerfully endowed with scent as its rival, *Wichuriana rubra*. This latter is a Rose worth possessing. It has the light green foliage of *Crimson Rambler*, to which it owes its existence, the trusses of single flowers much resembling *Pink Roamer*, albeit, the Violet-like fragrance is almost as powerful as in the white *Banksian*.

Treatment of Fancy Pelargoniums (E. S.).—These plants, as they are now going out of flower, should be set out-of-doors for a rather less supply of water than usual, and should have a rather dry them off. In about a fortnight after being put in the open air they may be cut back, leaving three or four eyes beyond the old wood. Place them in a frame with plenty of air on, and keep just moist at the roots until they begin to grow freely, and when the young shoots are about 2 inches long they should be shaken out of the old soil and be repotted into small pots as the roots can be got into. Use a rather light, loamy compost, and put them again in the frame, keeping it close and slightly shaded from hot sun until the plants are rooting freely, when they may have all the sun and plenty of air.

Management of a Fern-case (C.).—One of the most important points to attend to is to secure in the first place thoroughly efficient drainage. To effect this place over the bottom of the case some 3 inches of crock broken brick, or any such material, on a layer of broken brick, for the purpose. On this drainage put some pieces of turf peat, so that the finer particles of the soil cannot well mingle with it. The compost itself should be the best peat, adding to it plenty of silver-sand and some fragments of sandstone or some clean pebbles. The soil, not being exposed to the influence of the exterior atmosphere, there will be no need for frequent waterings and which should at no time be of a heavy nature. The box of the case should be opened for an hour or two in the morning to allow of the air there being changed.

Plants for sunless windows (A. R. J.).—Ferns, Mosses, and other fine foliage plants will grow in the north windows, or, to come to details, try the following:—Ferns: *Asplenium marinum*, *Oxyria*, *Filix-mas cristata*, *Polystichum angulare cristatum*, *Scopolopodium vulgare multifidum*, *Adiantum pedatum*, *Cyrtium falcatum*, *Mosses: Selaginella Kraussiana*, *Grass: Isoplepis gracilis*, *Finch-leaved plants: Cyperus alternifolius*, *Bracea indivisa*, *Fartugium grande*, *Ficus elastica*, *Grevillea robusta*, *Coprosma Baueriana*, *Abutilon Thompsonii*. Many of the dwarfier forms of Cacti will do if kept dry, and moved into the sunshine for a month or two in the year to ripen their growth. All the *Mimulus* family will flower in the north windows, including *Harriet's Musk*.

Rose La France with hard buds (Miss Paris-shire).—We fear the main cause of the buds on this Rose failing to expand is owing to the plants being excessively manured, which has caused a very gross growth. *La France* expands very indifferently in the early summer, especially if we have a cold June, such as this year, and the artificial manure would tend rather to aggravate matters, for it merely enlarges what at all times is a very double Rose. We presume you are sure the variety is *La France*. There is a Rose which much resembles it, named *Danmark*, that is most hard to open, but this one has a different habit from that of *La France*, being produced by stiff stems, and the buds are borne more erect than those of *La France*. If the buds still show no signs of opening, we should advise you to cut all off and prune the growth back to the first promising wood bud. The second blossoms rarely give any trouble in expanding freely.

TREES AND SHRUBS.

Growth on Lime-tree leaves (A. Greening).—The growth on the leaves of your Lime-tree are galls, commonly known as *Nail galls*. They are formed by a very small mite (*Phytopus tilie*). The best way to destroy this pest is to gather the infested leaves and burn them.

Failure of Acacias (J. G. K.).—The Rose *Azalea* propagated both by grafting and budding, and there is no apparent reason why your grafts have all failed. As they have done so, your better way will be to bud the stocks, which the present rain should make ready for working. Cleift-grafting is the method generally followed for the increase of this *Rubus*.

Hardy Azaleas (A. Z.).—The hardy *Ghent* or *Japanese Azaleas* will do well out-of-doors planted in beds of peat or other good turfy soil. They may be lifted and potted for forcing in autumn. They do not require much pruning, though a straggling shoot may be removed when necessary. They will spring from cuttings of half-ripened wood; but they are best increased by layering.

FRUIT.

Strawberries failing (Strawberry).—The frost in May did incalculable damage in many gardens, and it had not appeared to have crippled the fruit where it did not destroy it altogether, and it is as a result become misshapen, and did not swell up properly. From the appearance of the leaves sent, your plants seem to have been attacked by mildew. Keep the plants clean, and they will probably do well next year. It is possible that they may be dry at the roots? If so, this would cause the fruits to fall to swell.

Summer-pruning Currants (C. J.).—This, although a good practice if judiciously, is liable to do more harm than good if carried to excess. The effect of cutting off nearly all the growth, as we have sometimes seen done, is anything but beneficial to the bushes. It would strongly advise, however, the stopping of the shoots early on trees trained on walls, as if this is left too long

the lower leaves drop off, and without good foliage the fruit never ripens well. On open banks in the open country...

Management of fruit-trees, etc. (Amateur Grower).—From the appearance of the leaves seen it is evident that the trees are swarming with fly (aphides), and for this they should be well and frequently washed...

Figs falling (A. Martyn).—Fig-trees only ripen their fruit in the open air when planted close to a warm south wall, and to the branches called in thinning so as to allow...

Treatment of a Peach-tree (E.).—It would be a good plan to give a thoroughly good soaking of water to the roots of the Peach-tree. Some weak, clear manure-water...

Treatment of Vines (V.).—The Vines should have been "dabbed" soon after they broke into leaf, in accordance with instructions frequently given in GARDENING ILLUSTRATED.

VEGETABLES.

Late-sown Parsley (V. A.).—Yes, where large quantities of Parsley are required at this season it is a good plan to make a late sowing...

Nitrate of soda for Asparagus (E. M. M.).—About 5 oz. of this is sufficient as a dressing to each square yard for Asparagus-beds, spread evenly and in a thin powdered state.

SHORT REPLIES.

G. Dutton.—The only thing you can do is to put your birds (so often mentioned in these pages) round the stem of the tree early in October. Pick off all the ripened fruit and burn it.—F. J. S.—You ought to put screens in the house now, and if opening too quickly for winter purpose, shade them.

uncommon. We have it at present in bloom in a London garden, and have had it sent for name on several occasions lately.—Dora H. Lunt.—Certainly not. A shallow rooting annual will do no harm, but strong rooting plants will cripple the Vines.—E. W.—Cut away all the young canes, leaving only five or six of the very strongest to produce the crop next year.—D. Shubbrook.—See reply to "E. A. R. W." re "Rising Rhododendrons from seed," in our issue of June 21, p. 219. Yes, it is honest, but you ought to get it analysed.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, Furnival Street, Holborn, London, E.C.

Names of plants. G. H. C.—Rose fallen to pieces. Rev. R. Stowell.—Kindly send again, and mix a number in each specimen. See our notices to correspondents.—L. H. R.—3, Philadelphus grandiflorus; 2, Philadelphus coronarius.—Huetulius.—We cannot undertake to name Roses, being unable to compare them in any way.—M. Harker.—We cannot name florist's flowers.—Janice Lower.—1, Habena bifida; 2, Habena viridis; 3, Ophrys aquile; 4, Ophrys maculata var.; 5, Histeria orata; 6, Ophrys pinnatifida; 7, Ophrys coarctata; 8, Not recognised, too small; may be a form of No. 4.—Jimmy Pip.—1, Ribus odoratus; 2, Delastria scutellaria; 1 and 2, Spiraea sorbifolia; 3, Thalictrum lucidum, probably. It is not possible accurately to name such things without foliage.—Tie.—Raphiolepis japonica (ovata).—Delta.—3, Anthericum Liliastrium.—F. L. Smith.—1, Campanula Medium; 2, Specimen insufficient; 3, Delphinium Belladonna; 4, Aquilegia canadensis, poor form.—Jack.—1, Schizanthus retusa var.; 2 and 3, We cannot undertake to name Roses.—A. E. G.—Masterwort (Astrantia major).—A. Lover of Roses.—We cannot undertake to name Roses.—C. J.—Polemonium Richardsonii.—Mrs. R. Eversley Jones.—1, Lychnis Viscaria fl. pl.—B. and S.—1, Linnaea borealis.—Barkham.—The Ramanas Rose (Rosa rugosa).—R. V. S.—1, Taxodium sempervirens; 2, Veronica longifolia subscissilis; 3 and 4, Forms of the Evergreen Oak (Quercus ilex).—W. Thos. Colson.—A. A. of the Peruvian Lily (Alstromeria). It is unfair to send only single pups without any foliage when you want us to name plants.—Fennel Piper.—1, Quite dried up; 2, Sidalcea candida; 3, Inula glandulosa; 4, Comanthus sp.—no flower remained. Your specimens with numbers rolled and tied up give much unnecessary trouble.—A. G. J. W.—So far as we can determine, the specimens belong to the "Star of Bethlehem," or Ornithogalum, a very extensive genus of hardy and hull-hardy bulbous plants, some of the hardy kinds being of a very weedy nature. It has certainly nothing to do with Asparagus, and we would not care to partake of such doubtful food.—Puzzled.—1, Wall Pellitory (Parietaria officinalis).—Lupitree.—1, Should like to see specimen with complete flowers; 2, Cephalaria tatarica.—A. B. N.—1, Geranium steircicum; 2, Geranium arvense; 3, Cephalaria tatarica; 4, Veronica longifolia subscissilis.—Miss Burr.—We cannot undertake to name Roses.—G. M. S.—1, Campanula capitata alba; 2, Ornithogalum pyramidale; 3, Aconitum ochroleucum; 4, Sedum pulchellum.—J. L. Reid.—Evidently Campanula persicifolia fl. pl., but hard to say from a single crushed bloom as you send.

What you get for your outlay. Is the important thing for you. Buying from us you get greatest value—the middle profits for yourself—and no risk or worry of the instalment system. Our famous Silver Lever Watches are ticking the time to millions. Guaranteed for 7 years a lifetime of service in them. The 'ACME' 25/- Sent post free by return, a receipt of your remittance 25/- together with the gift of a handsome Silver Albert. The full value is in the watch, the bonus is part of our system to encourage cash trading. Solid Silver Case, fine 3-plate movement, jewelled, fitted with dust and damp-proof removable cap; the latest patented improvements; these features are in our watches exclusively. If you want it on approval, send 5/- only, and the balance in 7 days if you are satisfied. If not, we return the money for the watch. Write To-day for Our Free Catalogue. 260 pages, 3,000 engravings of watches, clocks, chains, cutlery, &c. Full of money-saving information. Posted free to you. H. Samuel, Dept. 65, MARKET STREET, MANCHESTER.

WEST'S INSECTICIDE. Before wasting money on worthless imitations, test a FREE SAMPLE, and yourself decide on its merits. It will cost you nothing, and prove to you that WEST'S PATENT GARDEN SUNDRIES PLANTS PROTECT, MONEY SAVE, AND LABOUR EASE. WEST'S PATENT AERATED SPRAY SYRINGE The best and cheapest for all purposes. Cannot get out of order. Price 5/6 car. paid. Buy from the Manufacturer of all Horticultural Sundries—C. E. WEST, ROUNDHAY (SUFFICIENT ADDRESS). Catalogue, containing 50 large pages, with 100 illustrations, with hints on Horticulture, post free. No Trade terms possible off these low prices.

BOOKS FOR THE GARDEN.

THE ENGLISH FLOWER GARDEN. Design and Plants. With full descriptions of all the best plants, their culture and arrangement, beautifully and extensively illustrated with fine engravings. Medium bro. 12s.; post free, 12s. 6d.

* **THE ENGLISH FLOWER GARDEN**—two vols.—but bound as one volume—suitable for library or presentation. Price one guinea net. Henceforward the book may always be had in this form.

GREENHOUSE AND STOVE PLANTS. FLOWERING AND FINE-LEAVED PALMS, FERNS, and LYCOPODIUMS, with full details of the propagation and cultivation of 500 families of plants, embracing all the plants in cultivation. By THOMAS BALMER. From the post free, 12s. 6d.

* A few copies of the previous edition of Greenhouse and Stove Plants (not illustrated) are offered at 5s. net, post free.

THE WILD GARDEN; OR, THE NATURALIZATION AND NATURAL GROUPING OF HARDY PLANTS, with a chapter on the Garden of British Wild Flowers. Fourth Edition, with wood engravings by the author, by A. J. B. BAKER, revised and enlarged. Demy 8vo. bound boards, price 12s.

* **THE WILD GARDEN,** special edition, printed a hand press on finest hand-made paper, well bound in cloth, one guinea net.

VILLA GARDENING. A handbook embracing all gardening in all its branches, with eighteen chapters specially devoted to Ornamental Gardening. By E. ROBERTS. Price 5s.; post free, 5s. 6d.

A DICTIONARY OF ENGLISH NAMES OF PLANTS, in two Parts—English-Latin and Latin-English. By Wm. MITCHELL. 12s.; post free, 12s. 6d. A work of reference which extends over a large field, including cultivated native and foreign plants, trees and shrubs—Times, July 25, 1885.

TOWN GARDENING. A Handbook of Trees, Shrubs, and Plants suitable for Town (Urban) and the garden, window, or greenhouse. Price 1s.; post free, 1s. 3d.

FRUIT CULTURE FOR PROFIT. A Handbook giving full information for the culture of fruit for profit. Price 1s.; post free, 1s. 3d.

GOD'S ACRE BEAUTIFUL; OR, THE CREMATORIES OF THE FUTURE. Third Edition. With illustrations. 1s. 6d.; post free, 8s. Published in a cheap form, and with additions under the name CREAMATORIES AND UEN BURIAL. 1s.; post free, 1s. 3d.

LONDON MARKET GARDENS. Showing the manner in which flowers, fruit, and vegetables are grown for market. By C. W. SHAW. Price 1s.; post free, 1s. 3d.

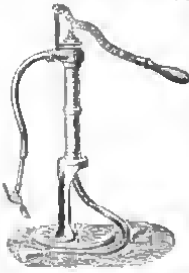

THE POTATO IN FARM AND GARDEN. Embracing every phase of its cultivation, with chapters on disease and special cultures. Price 1s.; post free, 1s. 3d.

THE APPLE IN ORCHARD AND GARDEN. Containing full account of its culture, with special chapter on Apple Cookery. Price 1s.; post free, 1s. 3d.

THE GARDEN ANNUAL FOR 1902. Contains Alphabetical Lists of all Branches of the Horticultural Trade. The Lists of Gardens and Country Seats (comprising over 3,000) have been very carefully and extensively revised, and are admitted to be the most complete ever published. Price 1s.; post free, 1s. 3d.

FRUIT.

STRAWBERRY TIME.

It is the time of flowering, Strawberries in field and garden in this neighbourhood promised well—at any rate, young plantations. The successive frosts occurring then had a most depressing effect on all concerned, and the prospect seemed to have suddenly dropped from a high standard to that of very low degree. In early districts, and where there was no shelter, no doubt a great proportion of the forward flowers, open and on the point of expanding, were destroyed. Despite the untoward weather, however, it is surprising how well and how bounteous is the Strawberry crop. Large fruits, it is true, are in the early crops wanting, but, all the same, there is a very fair sample to be gathered. Royal Sovereign has become the universal favourite, taking the once-honoured place of St. Joseph Paxton. This with some still claims some favourable notice, though to a much less degree than, say, five years ago. The same may be said of Vicomtesse H. de Thury, President, and Noble, once such standard sorts. Royal Sovereign is a bright-coloured, good-flavoured sort that has come to stay—until, at any rate, the newer Laxton supplants it, which will require some years to effect. Leader, in my case, takes precedence over Royal Sovereign because of its freer cropping powers and earliness. This is not the experience of growers generally, but in isolated instances it is true, nevertheless. Much finer fruits of brighter colour and greater weight of crop are the attributes of Leader, when compared with Sovereign in this garden. It may not be so in my neighbour's case two miles away, but it would seem that Royal Sovereign has such firm hold on the grower and purchaser that one is grown because the other remains unproved. No one who sees them fails to admire the sample of Leader gathered here in a normal year, nor would there be any doubt about their marketable value pitted one against the other on equal terms, yet, for all this, Sovereign still holds the place of honour, and seems likely to do so for some time to come. There have been a great many varieties sent out by Strawberry specialists and raisers, and planted only to be cleared out after their first year's trial, not always, perhaps, because of inferior merit as a variety, but simply because in some constitutional degree they are not suited to the soil or neighbourhood. Time was when a great many varieties shared space now monopolised by Royal Sovereign, and despite the fact that there are almost, or quite, one hundred recognised sorts in cultivation, Royal Sovereign, though of so recent introduction, in some degree crushes a great proportion of them out of existence. There would seem to have been no other kind at any period that has taken so firm a hold on the English growing public as this one. In Scotland it may not be such a success, soil and climate having an influence on the ripening berries, which prevent their

proper maturity. No Strawberry can withstand continuous rain or soddened soil without loss from premature decay when they are allowed to rot on a straw bed, and Royal Sovereign, though such a favourite southwards, does not hold the same position, I am told, in the moister climate of Scotland. Next to those already named, Fillbasket would appear to be the favourite. This certainly is correctly named, for its cropping powers are extraordinary, and the vigour of the plant a strong point in its favour. Mentmore, another good variety, has the failing of being very thin and sparse of foliage. The old-fashioned plan of laying nets on the beds as a protection to the fruit against birds would in this case be useless. The leaves are so thinly disposed that they afford no shelter to the fruit, and the weight of a net bears them to the ground. Nets are always better supported on strong string or light rope, and carried clear of the plants, but it is particularly necessary in thin-leaved kinds, such as Mentmore. Trafalgar is under trial, but as yet not sufficiently proved to venture an opinion. Though Sovereign has a probable rival in the Laxton, needing only time to gain its position, the older Latest of All still holds its own as a large-fruited and later variety. Certainly it is not without its faults, but in some soils, at any rate, it is excellent. Two Strawberries largely grown in Scotland, Aberdeen Favourite and Eliza Rivers, both in my case promising well for late gathering, are as yet some time behind all others, even Latest of All.

Trounbridge, Wills.

NOTES AND REPLIES.

Planting Strawberries.—I am going to make a bed of Strawberry Royal Sovereign. Will you kindly let me know the distance I should keep them apart, and what would be the best manure and soil to plant them in?—G. WATTS.

[For growing Strawberries it is always best to choose soil that is inclined to be heavy than otherwise, but it should be well drained. Light soils may be made more suitable for Strawberry growing by the addition of loam of a heavy texture or road sidings. This should be well dug in and thoroughly incorporated with the staple. Such a dressing is better than applying quantities of manure. Heavy soils, on the other hand, are greatly benefited by being well manured, and the manure should be thoroughly decomposed. In choosing a site for a Strawberry plantation ignore low, damp situations, for although the Strawberries may succeed in a dry season, they would in a wet time fall a prey to mildew, and the fruit would rot. The digging done, matters may be left alone until the plants are ready for setting out, and then the soil should be made quite firm by trampling it evenly all over previous to planting. This will make a good firm bed for the plants to root into, and it will also in a great measure prevent the plants being thrown out or lifted by frost during the winter months. Some few hours before planting, the young plants should be well watered, and it is also a good plan to water them home directly the planting is completed. A trowel should be employed for setting out the plants and pegged-down runners.

and the soil must be made very firm about them. On light soils a mulch of spent Mushroom-manure or suchlike material spread round about the fresh set-out plants is of great assistance in preventing them drying quickly and needing so much water. On heavy soils, which naturally retain more moisture, mulching is not so essential. The usual distance for planting Strawberries is 2 feet between the rows for gardens and 3 feet for field culture, and the plants may be set out 18 inches apart. If planted closer than this every other plant would have to be lifted the second season.]

Peach Amsden June in cold-house.

—In gardens where there is no glass accommodation for forcing Peaches, or where there is a lot of cold-house or wall space devoted to Peaches, the early kinds can be recommended, as frequently there is a glut in the mid-season. But if room is given to the best of these early kinds, then fairly good fruit may be had from June till October, and this without the expense of fire-heat. Were I asked if I considered any of these early kinds good flavoured, my answer is they are not, compared with such as Noblesse, Diamond, and others of this type; nor can this be expected when it is taken into consideration the short space of time they take from the blooming to the ripening. Out of them all I consider the one above named the best, and when grown in a sunny position and the tree vigorous there is not much to complain of, either in size or colour. I have a tree 12 years old in a cold Peach-house (which is not one of the best constructed houses), and I generally can obtain the first dish during the last few days in June. This keeps me going till Hale's Early comes in. This is followed by Acton Scott and other old proved kinds. The tree with me is a good grower and fruits freely. It is not liable to bud dropping, which cannot be said of some others. When exposed to the sun the colour is good.—J. CROOK.

Renovating a garden.—I have been asked to plan out a fruit garden in Fife-shire, and would be obliged if any of your readers would help me. The place has been very neglected for many years, and overgrown with weeds. I thought of having it dug up and manured now, so as to make use of the ground as soon as possible. I am, however, told this would be a mistake and labour lost, and better left it be until October, when it would be easier to trench. There is an immense number of Red Currant-bushes, some 7 feet high. Would it be possible to cut them down now to about 4 feet? The bushes look healthy, but have hardly any fruit. Even if I cannot cut them hard back now, could I thin out some of the dried-up looking branches? Can I shorten new shoots at once, or after the fruit ripens?—FIFE-SHIRE.

[In so northern a district as yours we think the advice given you to have the garden overgrown with weeds dug up at once is best. You can begin by cutting down all weeds as close to the ground as you can, allowing them to partially dry, then burning them. Also cut down your overgrown Red Currant-bushes to a few strong young shoots at once. Then, if you can get the labour now—and all depends on that—have the entire area well trenched, burying the weeds and 4 inches of the top soil. The weed rubbish would then soon decay. Your best course would be to plant any description of winter greens, and keep the ground between them well hoed. In November you could plant fruit-trees and bushes

where needed, pulling up any winter greens if in the way. In any case you would both get some winter crop and keep the ground clean. In the spring give a dressing of manure, and plant early Potatoes between the trees; that would clean the ground thoroughly.]

PLANTS AND FLOWERS.

ROSES.

ROSES IN POTS.

WHEN a batch of plants has once been used for early forcing they naturally come to hand better for the same purpose another time, because the earliness of their growth allows of a corresponding earliness in ripening. Plants that were grown in heat all through the winter and early spring should be standing out-of-doors now, especially if a sheltered position can be afforded them. During the two or three months they are in the open it is necessary to be particularly careful as regards watering. If given too free a supply, growth will not cease in the gradual manner so essential in building up ripened wood for the following winter's forcing. On the other hand, almost as much harm may accrue from a little neglect, it taking but a short time for the soil to become so parched as to ruin a large number of the Rose roots. They may be allowed to get dry without being sufficiently so to show the effects, and it will be found much better to give a thorough soaking occasionally. It is advisable to have the pots about half plunged, and if this can be arranged upon a concrete bottom, so as to avoid worms, it will be still better. Standing the pots upon pieces of slate is not to be recommended, for a very little soil washed to the bottom will cause a stoppage. Worms, etc., may be kept out by sprinkling a layer of soot over the ground and standing the pots upon this. By partially plunging the pots, we avoid that sudden and injurious drought which comes on so unexpectedly after a few hours of dull weather, and as the most important roots of pot Roses are usually in the lower half, it behoves us to take due care of them.

IN THE TIME OF ROSES.

THERE is no period in the whole year so attractive as June—the time of Roses. Our collection may number hundreds of choice sorts, or, on the other hand, we may have perforce to be content with a few; but however well stocked our garden may be, if we really love Roses we cannot fail to display an eagerness in their welfare, and watch for the opening of the earliest blooms. It is a question whether any other subject responds to generous treatment so liberally as does the Rose, and in a similar degree it is one of the first to show signs of neglect; moreover, it often tries one's patience. Take, as an example of this, the experience of the past spring. One knows only too well, after the cutting back at the end of March and April our May weather was anything but mild and genial. Here, as I write, I am reminded that on May 15th we were visited by a snow-storm, with north-east winds for days that starved and almost completely killed some of the tender Teas, so that blooms this season are, generally speaking, backward; but, after all, Roses have wonderfully recuperative powers, and early in June it was delightful to notice that many of our old favourites, though somewhat behind, were little the worse for their experience of wintry weather in May.

When one comes to consider the all-round use of the Rose one cannot be surprised that it continues to be so popular, nor can one wonder that each year "new hands" in Rose growing are added. One cannot say of it that it is a town flower, because its liking for purity of atmosphere is so well known, but it is a fact that, nevertheless, some varieties give not a little satisfaction in places where one would hardly expect them. Three such are Crimson Rambler, William Allen Richardson, and Gloire de Dijon; but, given space away from smoke, how liberally the Rose responds. Whilst the Hybrid Perpetuals still retain with a considerable number their popularity, and will doubtless continue to do so, one

cannot shut one's eyes to the fact that the Hybrid Teas are fast gaining ground amongst growers, mainly, I think, owing to the continuous blooming propensities of some of them, and the lovely varieties which this class contains. Take, for instance, the following well-known sorts: Viscontess Folkestone, Mrs. W. J. Grant, Liberty, Kaiserin Augusta Victoria, Grace Darling, Clara Watson, Bessie Brown, Augustine Guinoiseau, Lady Mary Fitzwilliam, La France, Papa Gontier, Souv. de President Carnot. The Hybrid Sweet Briers are steadily gaining in favour, and the delicate flowers and deliciously scented foliage should commend them to all who are interested in Roses. In

PLANTING Roses, one should bear in mind the late-blooming qualities of many of our Teas and Hybrids, and with this end in view every collection should include Mme. Lambert, Hon. Edith Gifford, Safrano, Marie d'Orleans, Belle

Mme. Isaac Periere, that remain with us until late in autumn.

I have a friend who for many weeks during the past winter trudged in all weathers to his garden away from home to look after his Roses, some of them being newly planted and needing extra care in consequence of their late arrival. His beds of Teas were in November mulched with manure, and subsequently had a littering of straw amongst them, which shielded the plants during the cold periods in April and May. It was due to this attention that only an odd one or two succumbed; hence it is that now, as I write, his W. A. Richardson, Maman Cochet, La France, Réve d'Or, L'Idéal, and the rest of his favourites give promise, by their healthy buds and foliage, of a glorious display.

No, the Queen of Flowers will brook no neglect, and if we would have her in perfection in June, she claims our attention even when no

Tea Rose Niphetos in a pot.

Lyonnaise, Enchantress, Mme. Hosto, and Caroline Testout. As has already been remarked, Roses quickly show carelessness and inattention. Most of us have found this out at one time or another, in climbers or on house walls, but, on the other hand, the grower who evinces an interest in his plants the year round is the one who obtains the most satisfaction. Consider for a moment, too, the all-round fitness of Roses. Is it a wall, a porch, an arch, or an arbour one wishes to festoon, a bed or border one is desirous of beautifying? Then we may have varieties for each position, lovely buds peering out of leaves frail and tender, delicate clusters nestling under house eaves and around doorways, huge bushes like the Ayrshires, Polyantha Roses, of which Crimson Rambler and Aglaia are examples, China Roses of dwarfier growth, with fairy-like blossoms, single Roses, as Carmine Pillar, Bardou Job, a most charming class, and Bourbons, represented by Souvenir de Madame Paul, Purity, Mrs. Paul, Lorna Doone, and

tokens of blossoms are to be seen, and in proportion as we devote time and labour to her cultivation, so will our gardens be enhanced by her beauty. After all, it is the same old story. Dean Hole is right, for

"He who would have beautiful Roses in his garden,
Must have beautiful Roses in his heart."

LEAHUEST.

ROSES IN A HERTFORDSHIRE GARDEN.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—In the issue of June 25 "Rosa" expresses regret that this year he has only heard of Roses being in fine bloom in Devonshire, and that elsewhere only Scotch Roses, Rugosa, and Austrian Briers were fit to cut, so I feel inclined to say a word for the good Rose soil of Hertfordshire, and a word, too, for the cultivation of Roses in my quaint cottage garden. At this moment (July 2, only three days later than the letter referred to) the garden is simply a bower of Roses, and I must

try and describe them, and also the manner of arranging them, which is very successful. On the verandah of my house Reine Marie Henriette and Gloire de Dijon give us two colours that blend beautifully. In the drawing-room, which I have just decorated, a high old English table holds specimen glasses with fine blooms of pink Maman Cochet, La France, and Mme. Abel Chatenay. On a low, round table an Italian 15th century glass bowl shows perfectly shaped Kaiserin Augusta and white Maman Cochet. In a green bit of pottery, with a high arched handle, some well-coloured blooms of William Allen Richardson form a delicious background to a large oriental bowl full of Mme. de Watteville, with the mother of pearl delicate petals standing out strong and full to show the lovely tinted centre. On an old Italian stand in the window I have a white and gold miniature cradle with a glass lining, in which I have placed those perforated china holders that support flowers erect, where necessary, and have filled it with Mme. Lambert, Rainbow, and Dr. Rouges, supported on either side with large, brilliant blooms of Captain Hayward. One more gem still—a large Leeds bowl holds a vase full of Marie van Houtte. As I sit looking out on my garden my eyes turn to my pergola, and there the shining Carmine Pillar, Climbing Mme. Bizard, Austrian Brier, Gruss an Teplitz, and Gloire de Dijon, interspersed with Ikonysuckle and Sweet Brier Penzance Roses, rejoice my heart. I left a long border of Roses unpruned, and have been richly rewarded by such a show of bloom as I have never had before. I wanted for once to see if they would grow as they do in Bordighera, and I am revelling in the result. I think the desire to grow immense blooms for exhibition causes Roses to be pruned very hard and then ruthlessly disbudded, so as to produce one or two enormous blooms. It may be well for florists to do this in the hope of getting prizes, but surely it is most inartistic. A Rose-bush never looks so beautiful as when it is growing luxuriantly in a suitably chosen position, well nurtured, well opened out to light and air, and producing blossoms that may not be perhaps so enormous as those in exhibition boxes in a Rose show, yet large and sweet enough to fill a Rose lover's heart with delight.

LEILA.

NOTES AND REPLIES.

Rose Niphetos.—I have a Niphetos Rose here in the greenhouse. Should I pot it outside after flowering?

—(The ought to encourage new growth as much as possible by frequent syringing and a somewhat close atmosphere. Towards autumn endeavour to ripen the wood by partially withholding water and standing the plant outdoors until October. See article and cut of Rose Niphetos in a pot.)

Rose Gruss an Teplitz.—I planted out a bush of this Rose in the spring of last year, and it did splendidly. This year, however, it has not flowered, although making rampant growth. Ought I to do anything to arrest this and induce flowering? A bush of this Rose, planted out last November, is blooming well.—G. M.

[This Rose is really a half-climber, and produces its fine trusses of bloom at the ends of the strong growths. The plant you set out last year has now become well established, and in consequence is growing vigorously. These growths will flower, although somewhat later than those upon plants put out this spring. You will find it a good plan to loosely tie the long shoots to sticks for a season or two. When the growths produce laterals, then you will obtain many trusses of blossom on each growth, but we should not advise you to interfere with them now beyond tying as described.]

Budding Roses.—Will you kindly state what sorts are suitable to bud on to other classes?—i.e., will H.P.'s do if budded on Teas, and vice versa? Or Teas on Crimson Rambler? Or must one type be budded only on to another variety of same type? What is suitable for budding Penzance and Austrian Briers on to?—EUDINO ANITA.

[There is little advantage, if any, in budding Roses upon cultivated tribes. For instance, it would be unwise to bud H.P.'s upon Tea Roses, for the simple reason that the stock would be liable to suffer from frost. This is why some cannot grow Roses on the Manetti, this being rather tender. There are various species that could well be employed for stocks with considerable advantage. Many use Rosa polyantha as a stock, and it is first-rate if the plants are not transplanted from where budded. Strong growths of this planted deeply may be budded in the stem, and quite free-headed

half-standards are the result. The de la Grifferaie stock is also good for many of the strong-growing Roses of the Gloire de Dijon race, but for all general purposes no stock can surpass the Brier, either seedling, cutting, or standard. Crimson Rambler would make a good stock, as it roots so freely from cuttings. So also would some of the hardy Ayrshire and Evergreen Roses. Maréchal Niel and Cloth of Gold are often most successfully grown upon the yellow Banksian Rose, but in this case the latter must be well established. I have much faith in double budding some of our difficult to grow Roses, as fruit-growers do with their Pears. I once obtained a fine plant of Cloth of Gold by budding it upon a Chesbunt Hybrid, which was budded on the de la Grifferaie stock. Tea Roses would do well on Crimson Rambler, but they should not be transplanted. If you desire to bud the Penzance Briers, the Manetti is the best stock, but most of them strike freely from cuttings, and this is better in the end than budding. Austrian Briers must be budded on Manetti or Brier-stock.]

FERNS.

THE OAK FERN (POLYPODIUM DRYOPTERIS).

Of the four native species of Polypodies with deciduous foliage, the Polypodium Dryopteris,

cool, sheltered, moist places where the temperature is subjected to very little variation during the summer. In planting the Oak Fern, a spot where moisture and shade can always be depended upon should, if possible, be selected, and a shallow bed made of a compost of two parts of fibrous peat, one part of leaf-mould, and a free admixture of silver-sand, or, better still, of broken sandstone. If grown in pots for a cool frame or the greenhouse, where it makes a most pleasing object, as in the illustration herewith, the above mixture will be found equally suitable; but in either case avoid putting in too much soil; a depth of from 3 inches to 4 inches is quite sufficient. It is also indispensable that thorough drainage should be secured, for, although the growing plant delights in an abundant supply of water, yet water remaining about its roots is very injurious to it. In planting, great care must also be taken to prevent the rhizomes being buried too deeply, in which case they seldom grow; they must be only just below the surface of the soil, which should only cover them lightly, and through which it is advisable to let the tips protrude. After the planting, a moderate watering must follow, after which the soil requires to be kept constantly moist until the new fronds begin to unfold, when, as they increase in size, a free supply of water will be necessary to keep the atmosphere always moist about the plants. This Polypody is readily increased by division.

The Oak Fern (Polypodium Dryopteris) as a pot plant.

or, as it is popularly called, the Oak Fern, for which appellation there is no reason, unless it be that it is so named from being sometimes found among the Moss about the roots of Oak-trees, is undoubtedly the one most generally known, as it also is the one growing most abundantly in a less restricted habitat. On account of the peculiarly bright pea-green colour of its short, triangular fronds, which seldom exceed 10 inches in height, and also of its compact and close habit, it is much admired and generally used for forming in the hardy ferrocyedgings which all the summer possess a freshness looked for in vain among any other Ferns of dwarf habit. These ferns have, when only partially developed, a very peculiar aspect, as the pinnae on each branch are rolled up, resembling so many small Green Peas; they are, like the fronds of all the other Polypodies, produced on slender, creeping rhizomes, which, contrary to those of the evergreen species and varieties, are strictly underground. The Oak Fern is always found in perfect

Although totally deprived of foliage during four or five months of the year, the Oak Fern should never be allowed to get dry at any time, for the rhizomes soon shrivel up and the spring growth then only produces small or deformed fronds, and the plants are very much weakened. It is also advisable to give plants grown in pots a slight covering during the winter, though not requiring the same attention when planted out.

A small number of Polypodies, such as our Oak and Beech Ferns, are provided with rhizomes of a slender nature, which delight in running underground in partly decayed vegetable matter, but in the majority of cases the rhizomes of either a fleshy or of a woody nature prefer being kept above or close to the ground, to which they have the faculty of adhering very firmly. The Polypodies best adapted for pot culture are those in which the fronds are produced from a central crown, although those provided with underground rhizomes may be managed equally well in pots

or planted, according to their native habits, either in the stove, cool rockery, or outdoor fernery. The soil which suits these best is a compost of one part leaf-mould or fibrous peat, two parts fibrous loam, and one part silver-sand. For those species which are provided with rhizomes of a more or less woody nature, which keep near, or even on the surface of the

from 8 inches to a yard high in moist parts of valleys and woods in the Alps and Pyrenees, is too large for cultivation in the rock garden among the choicer and smaller things; but its double variety is a beautiful old border flower. The flowers are not large, but are white and double, and resemble a miniature double white Camellia. A rich, moist soil will be found to

moist with a surfacing of grit, sand, or small stones, till the plant grows into a little spreading tuft.

R. BILOBUS is another form from S. Tyrol. **R. ANEMONIFORMIS**, a native of the Alps of Styria and the Southern Tyrol, is a handsome species, with bluish-green leaves; flowers large, with numerous divisions, of a greenish white on the inside and pink on the outside, appearing before the leaves and very early. It does best in the rock garden in a cool place and in moist, porous soil.

R. BELLATUS (Marigold Buttercup).—A dwarf stout perennial, easy to cultivate, with showy double flowers, the blossoms as large as those of the double Marsh Marigold. The plant thrives in heavy soil. Division of the roots.

R. CRENATUS.—A native of granitic mountains in Styria, with roundish leaves, the flowers large, white, two or three together at the extremity of stem, 3 inches or 4 inches high in April or May. It does well in the rock garden in gritty or open soil.

R. ELVITALIS (Arctic Buttercup).—A well-named plant, as it is an inhabitant of very high places on the Alps, and may often be seen in flower near the snow and in the Arctic region. The flowers are large, white tinted, of a dull purplish-rose on the outside; the calyx with shaggy brownish hairs, the leaves smooth, deeply cut, and of a dark green. It will thrive in a cool spot in deep, gritty soil, moist during the warm months. I have seen it thriving with its roots below stones. On the Alps it blooms in early summer; in our gardens somewhat earlier. It is easily raised from seed, and in its native habitat spreads about freely. This is the plant which Mr. Ruskin met with high up among the icy rocks, near the margins of the snowy solitude of the Alps, and which pleased him so much there. It is often washed down by the rock streams and found in the river flats.

R. GRAMINEUS (Grassy Buttercup).—A graceful plant, which may well represent on the rock garden the beauty of some of the taller kinds that are too vigorous for it. Easily known by its Grass-like leaves, 6 inches to 12 inches high. The flowers in May are yellow. There is a double variety, but it is seldom seen. Southern Europe. Division. An easily-grown plant.

Lady Buttercup (*Ranunculus aplexicaulis*). From a photograph by Mr. D. S. Fish, Edinburgh.

soil, a material of a different nature is required, and they have been observed to grow more luxuriantly in a mixture in which good fibrous peat or half-decayed leaf-mould predominates and with a small portion of fibrous loam. In their case no silver-sand is required. The propagation of the species provided with rhizomes may take place almost at any time of the year by division, while the others are most rapidly increased by means of spores, which in the majority of cases germinate freely when sown in heat and soon after they are ripe. It is worthy of notice that the plants raised from seed are usually of better shape than those of the same species produced by division of the rhizomes.

OUTDOOR PLANTS.

ALPINE BUTTERCUPS (*RANUNCULUS*) FOR ROCK GARDENS.

THESE are alpine, northern pasture, water and waterside plants, many of the perennial and mountain kinds from their boldness, hardiness, and beauty admirably suited for the rock garden. Although as interesting as any of the great families of rock plants, they are not nearly so difficult to grow and keep if care be taken to prevent them being overrun by coarser plants.

Mr. W. A. Clark, in "Alpine Plants," rightly attaches importance to top-dressing some of the higher alpine species, and says "that great care must be taken to top-dress or replant just after flowering, as the plants work out of the ground, and this can be done before the hot weather begins. If left without top-dressing they will no doubt shrivel up with the sun, as the roots will have been left all exposed. A sharp look-out for snails is essential in the early spring, as they often eat out the crowns before they are fairly above ground, and the flowers are lost for the season. A little rough grit will do much to prevent this occurring; if placed over the crowns the fine must be taken out, only using the rough grit."

R. AMPLEXICAULIS (Lady Buttercup).—A beautiful plant, with large white flowers having yellow centres, one to five blooms being borne on a stem, which is clasped by smooth sea-green leaves, which set off its snowy bouquet of flowers. I know no more graceful plant for the rock garden. A native of the Alps, Pyrenees, thriving in light, rich loam, usually growing 7 inches to 10 inches high, flowering in gardens in April or May, and increased by seed or division. It is worthy of the best positions, and is very pretty grouped in a free way.

R. ALPINUS (Fair Maids of France).—This white flowered plant grows

suit it best on the shady side of the rock garden, and among bog-loving shrubs.

R. ALPESINUS (Alpine Buttercup).—A diminutive species, from 1 inch to 3 inches or 4 inches high, and forming neat tufts, each stem bearing from one to three white flowers in April. The leaves are of a dark glossy green, roundish-heart-shaped, and deeply divided. It is a native of most of the great mountain ranges of Europe, in moist, rocky places on the higher pastures, and one of the best plants for the rock garden. It is not difficult to grow in moist, sandy, or gritty soil, in positions exposed to the sun and moist in summer.

R. TRACNFELNERI seems to be a diminutive

Arctic Buttercup (*Ranunculus glacialis*).

of the preceding, the whole plant, even as we have observed it in cultivation, being not more than 1 inch high. The same treatment will suit it; but, being smaller, it will require a little more care in selecting some firm position fully exposed to the sun and air, but kept

R. LVALLII (Rockwood Lily).—Dr. Hooker calls this plant the "most noble species of the genus"—"the Water Lily of the shepherds." Indeed, even in the dried specimens, of which there are many in the Kew herbarium, the resemblance to our common white Water Lily

is striking. The plant is said to grow in moist places in the Southern Alps, the Wurunui Mountains, in the glacier regions of the Forbes River, near Otago, and elsewhere in the Middle Island of New Zealand, at heights of from 1,000 feet to 5,000 feet above the sea. In habit it seems almost identical with our Marsh Marigold, but it is twice or thrice

as large. The leaves are circular, 12 inches to 15 inches in diameter, peltate, as in the Nelumbium, the flowers borne in panicles; each flower of the purest waxy white colour, 3 inches to 4 inches across. To raise a stock it has been recommended that the seed be sown in well drained pans or boxes filled with peat and coarse grit in equal parts, stood in a cool place on the north side of a wall, watered well, and covered with a sheet of glass.

nees, where it abounds. *R. plantagineus* from the Piedmont and *R. huplourifolius*, usually found in moist valleys in the Pyrenees at a much lower altitude, are varieties of the species. All have white flowers, and are of easy culture.

R. RETE-FOLII syn. *Callianthemum* (Rue Buttercup).—This, with deeply divided leaves, reminding one somewhat of those of a very dwarf Columbine, and white flowers with orange centres about an inch across; on stems from 3 inches to 6 inches high, bears from one to three flowers, sometimes rose-tinted on the outside. A native of high and cool parts of the granitic continental ranges; increased by seed or division.

R. SERRIERI (Seguir's Buttercup).—Like the Glacier Buttercup, about 6 inches high, with three-parted leaves, though distinct. Usually the flowers are solitary and rarely as many as two or three on each stem. The flowers are white, with distinctly rounded petals. Native of the calcareous Alps of Provence, Dauphiny, and Carniola.

R. THORA (Venom Buttercup).—The roots of this, like small Dahlias tubers, and said to be poisonous, were formerly used by the Swiss hunters to poison their darts. It is yellow-flowered, with very smooth leaves. It is yellow, distributed through Switzerland, the Carpathian and other mountain chains on rocks and in pastures near the snow-line, thrives in gritty loam.

WESTMORELAND WALLS.

My walls are not the grey walls of the Lake Country crammed with Maiden-hair and Parsley

called, built of huge boulders, or the old deer-forest wall, 6 feet high, exposed to wind and sun where nothing grows. These walls I call mine run for 150 yards north and south between Fir woods. The one facing west is the most picturesque, built of red sandstone and boulders, without mortar, with an irregular top of rugged stones of all sorts, into which I have inserted both soil and Stonecrops of many kinds, from the tiny one growing wild on the Ayrshire coast to the large white-flowering one from the walls of Savoie. The foliage—green, blue green, and red—sets off the yellow, white, and cream-coloured flowers. On the other side of the road the wall is less tempting for decoration, being our garden wall, more carefully built, and finished at the top in a crenulated style with mortar; it is all red sandstone. For some reason, however, everything grows better and quicker on it, whether on account of being less in the sun or because of the mortar, I cannot say. Here I have Saxifrages, red and white, Stonecrop, Thymes, etc., and, where it turns west with a sweep into the gateway, and the walls are pointed throughout, there is a fine crop of *Asplenium Ruta muraria* (lesser Mitten-hair), some Hard Fern, *Draba aizoides*, *Aulricia*, *Erinus*, and so on. Some *Helianthemum*s also are growing bravely. But the plant which prepared the way for better things, and lifted the stones and split gaps in the mortar, is *Linaria Cymbalaria* (the Ivy-leaved Toddlax), which in summer runs wild over the wall, sowing itself everywhere. Many seeds and other things have been tried, such as *Silene compacta*, *Sisyrinchium*, and various plants suitable for walls. I should like to grow the blue Iris like they do abroad, but here we seldom get the tropical showers of the Lake District. Our rainfall the last two years has been little over 25 inches for the year, and though the red sandstone is like a sponge and gathers in a great deal of moisture it dries up where exposed to the sun in summer, and the beautiful natural Mosses, Lichens, and Cup Moss get parched and burnt. I am trying also the Maiden Pink, and should like to sow the Cheddar Pink in the way recommended by Mr. Robinson in his "English Flower Garden,"

The Rockwood Lily (*R. lyallii*).

To English growers, the most interesting experience is that of Mr. Bartholomew, Park House, Reading, who has grown this plant well. His plant was on the north side of a summer house, in 2 feet of soil, chiefly peat, which was liberally watered all through the summer. When it died down in the autumn, a little Cocoa-nut-fibre was placed over the crowns, and, with a view to saving the plant as far as possible from alternate freezing and thawing, a sheet of glass raised on bricks was placed over it. It flowered freely and ripened seed at Reading. It also bloomed for three years in succession in a nursery at Aberdean, the seedlings having been raised there.

R. MONTANUS (Mountain Buttercup).—A dwarf compact plant with tufts of deep green, glossy leaves, covered in spring with many yellow flowers, somewhat larger than those of our common Buttercup. Although like the Buttercups in colour, it is unlike in its dwarf, close habit, usually flowering at 3 inches high, and, though growing freely enough, not spreading about with the coarse vigour of many of its fellows. It is a native of alpine pastures on the principal great mountain-chains of Europe, growing freely in moist, sandy soil, and should be planted so as to form spreading tufts, as it represents in a modest way the beauty of yellow kinds too vigorous for the rock garden. Readily increased by seed or division.

R. PARNASSIFOLIUS (Parnassia-leaved Buttercup).—Distinct, with beautiful white flowers, from one to a dozen or more being borne on each stem, which grows from 3 inches to 5 inches high, and is somewhat velvety, and of a purplish hue. The leaves are of a dark brownish-green, sometimes woolly along the margins and nerves. It is rare in gardens, though abundant in many parts of the Alps on calcareous soils. No plant is more worthy of culture in the rock garden in sandy, well-drained loam. There is a variety with narrow leaves.

R. PYRENEUS (Pyrean Buttercup).—A slender-leaved plant, 6 inches to 12 inches high, and from the Alps, as well as the Pyre-

Fair Maids of France (*R. aconitifolius fl. pl.*)

nean, nor yet the granite or limestone walls of the "Cyclopean walls," as they have been

if I could find where the seed is to be procured. Certain risks, of course, must be run on a public road from mischievous passers-

by, but my own neighbours would not take flowers off the wall, as I should be only too happy to give them any they wished for, and, fortunately, there are no tourists within four miles, so wall gardening, a very fascinating occupation, is possible here. M. V. B.

PINKS.

We can hardly have too many of these in the open borders or beds. For years I have noticed how frequently Pinks are seen in farmhouses and cottage gardens, where often may be found some of the best patches of many of the freest growers. Near to where I reside is a grand display of the common white as an edging to a large bed by the side of a cottage door. This edging is a foot wide. Seldom is this garden devoid of interest, for in midwinter may be seen fine clumps in full bloom of the large early Christmas Rose, which is quickly followed by early bulbs. During this summer I have been struck with the value of these border Pinks, from having a larges group of three kinds growing side by side in the reserve garden. They are as valuable as anything I grow for cutting. What can surpass large masses of Pinks for the mixed borders or beds? With a few kinds great variety in colour may be had, and a long period of blooming. They have many points to recommend them. They seem to grow in any soil or position, they need no staking, and their perfume is admired by all. O!

VARIETIES there are many, all more or less good. In whites, the common white will never be ousted from our gardens, seeing this has merits that neither Mrs. Sinkins nor Her Majesty has, although these last two are charming in dry weather. Ernest Ladhams is a fine free growing and blooming light Pink; Mrs. W. Welsh is a late blooming white; Homer, rose-red, dark centre, is very free; Ascot is a good clove-scented, pink in colour, and early blooming; nor must the old Puddington be forgotten—this is very early. Good as these are, the Mule kinds are equally so. Surely if these were more known they would be seen in all good gardens. The three kinds above referred to in our garden were two of these, hybridus and h. splendens, the former rose and the latter red, and Mrs. Sinkins. Napoleon III. is a deep crimson, and one of the gems of the hardy garden. The white Mule Pink I could never grow well. The good old Anne Boleyn used to be grown extensively. Derby Day and Lord Lyon had a run, and good they were, but they seem to have gone out of cultivation. All the kinds above named can be easily increased by cuttings, rooted under handlights in a shady place during the last half of July and August, in sandy soil. J. CROOK.

WILDFLOWERS WORTH CULTIVATING.

It would be of great interest to have records of the wild flowers peculiar to different districts. I am sure that there are many wild plants which, by interesting and careful selection, could be so improved as to merit a place among our most beautiful garden flowers. Many wild flowers in bloom this month are as beautiful as any flowers grown in our gardens. What can be more beautiful than two Thistles, which are in bloom on the chalk cliffs around the Mumbles, the Carline Thistle (*Carlina vulgaris*), and the Musk Thistle (*Carduus nutans*), and that most beautiful but rare Thistle, the Cotton Thistle (*Onopordon Acanthium*), which is found around here occasionally. Then there is the Great Spearwort (*Ranunculus Lingua*), easily grown and plentifully found in many marshes. Those who have seen a clump of the Marsh Mallow (*Althaea officinalis*), with its pink-rosy spike of flowers and its soft silky leaves, will not readily forget it. Among the Geraniums, *G. pratense* and *G. sanguineum* are easily grown and delight in sandy soil, and they are fairly common. Clumps of the French Willow (*Epilobium angustifolium*) and the Yellow Loosestrife (*Lysimachia vulgaris*) are also beautiful, and both are common. The Moneywort (*Lysimachia nummularia*) is the well-known creeper seen in rock gardens. For rock gardens nothing can surpass the Saxifrage and the Sedums. A very common Saxifrage found on walls and old thatched houses is *S. triactylites*, with its pink leaves and flowers. (The Pink London Pride

S. oppositifolia is rare, but it makes a beautiful rock garden plant. *S. granulata* is a beautiful plant for the border, with pure white blooms like an Arabis. It is surprising how wild flowers will accommodate themselves and grow in a garden in soils and situations very different from those we find them in in a wild state. The Sand Sedge (*Carex Arenaria*) will grow and thrive and send its creeping roots right across a flower bed of stitish soil. *Luzula maxima* will grow anywhere in a garden. The tall Reed (*Arundo Phragmites*), with its dark brown plumes, seen growing on the margins of pools and canals, will grow in an ordinary border.

All these "wild flowers" are worth growing, not only in the wild garden, but in our choice herbaceous borders. They last in bloom as long, they look as graceful, and are as beautiful as any of our hardy perennial flowers.

Gardens.

ROBERT LACKETT.

NOTES AND REPLIES.

Begonias in the open air.—Although Begonias will do very well in exposed positions, the situation that suits them best is a partially shaded one; but wherever planted it is important that they be mulched, so as to keep the ground shaded and the plants moist at the roots. This can best be done by the use of Cocoa-nut fibre, a good non-conductor of heat; but, failing the fibre, sifted leaf-soil or broken-up horse-droppings answer the purpose nearly as well. To encourage Begonias to grow and bloom freely they must be supplied with water regularly when the weather is dry; and if they get a soaking of liquid-manure occasionally it will be a great help. Late in autumn, when the flowering is over, the plants should be lifted and laid in cold frames, where the tubers can be covered with dry soil, and preserved from frost, or they may be buried in sand or dry earth in a shed, and be wintered in the same way as Dablias. Those grown in pots are best left undisturbed in the soil till the spring, when they may be shaken out and divided, and afterwards repotted and grown on again.

The Fuchsia as a bedding plant.—I was pleased to see in your issue of July 12th an article on the Fuchsia as an outdoor plant, and I quite agree with the remarks of your correspondent. It is a pity that more is not made of the Fuchsia as a summer bedder, as few prettier subjects can be obtained at so little expense to the cultivator. The beds look exceedingly pretty, and are a delightful change from the stiff, formal Aster, for instance. The plan on which I work is a very simple one. Instead of raising young plants from cuttings for the purpose, I plant out the one-year-old plants, previously, of course, taking sufficient stock from them to furnish plants for indoors. I find the old plants bloom more freely outside. It is wonderful what use can even be made of plants which have got leggy. I had a lot of Rose of Castillo of this stamp, most of them having a bare stem of about 16 inches. However, when planted out and the spaces between the plants filled in with Nasturtium Lilliput, scarlet, finishing with a border of *Cineraria maritima*, the effect was grand, the colours being in perfect harmony with one another. It is not necessary to confine oneself to any special varieties, as all classes of singles and doubles do well.—D. G. McIVER, *B. of W., N. B.*

Plants for sandy soil.—I have lately come into possession of a rather large garden, which is principally composed of sand, pure and simple. Although there are large Oaks on the grounds, and Laurels, etc., have flourished fairly well for the last forty years, yet Bracken is in full vigour, and that, I am told, is a sure sign of anything one ordinarily sees in gardens growing to any perfection. Would you very kindly, in your next issue, give me a list of plants (sweet-scented ones preferred) that will do in such a soil? It is a sloping position. Of course, Broom and Gorse thrive, and I conclude most bulbs would do, also Iris, and perhaps Stocks?—OWEN C. PHILLIPS.

[It most usually happens in such a soil as you describe that quite a large number of plants succeed that in cold or clay soils grow but poorly. It is quite probable a number of the warmth-loving, tender annuals would also succeed. Such things as Stocks, Sweet Sultan, Sweet William, Dianthus, Pinks, Phacelia, Mignonette, Rosemary, Lavender, Evening Primrose, many Irises of the English section, such

fragrant flowering shrubs as Daphne, Mock Orange in variety, Sweet Peas, Clove Carnations, Liliums in many varieties, would afford you much useful material to start with. In the border herbaceous things—double Rockets, Paeonies, and Phloxes—are good and fragrant also. To these you may add *Primula denticulata*, *P. Sieboldii* in variety, and such Day Lilies as *Heimerocallis flava*, *H. Middendorffii*, *H. Thunbergii*, all of which are fragrant and free. The Spanish and English Irises, the *Alstroemerias*, single and double *Pyrethrums*, *Columbines*, *Sunflowers*, *Perennial Pea*, etc., are others that, if not fragrant, are showy and suitable in such a soil. The latter, too, would be most congenial for many bulbous things—Daffodils of all kinds, Tulips, etc. What is most required in these sandy soils is deep digging, with heavy manuring low down to attract roots thither in dry weather. This and surface mulching will do much to enable you to grow many plants that on cold or heavy soils may be difficult to satisfy. Starch Hyacinths, and in particular the allied *Muscari conicum*, is a finely scented flower, beautiful in colour, and most delightful when cut.]

Candytufts.—Of garden flowers that one may characterise as "good old things," the Iberis or Candytufts may be mentioned. They are valuable where rock plants are cherished, are often seen doing well on old walls, and some of them are not without their use as border and edging plants. The common variety, *I. sempervirens*, is noted for its dwarf habit, its hardiness, and its quantities of white blossoms found at the present moment in many a garden. *I. gibraltaria* is taller, has flowers of a lilac hue, is not so hardy as the previous sort, and should be planted on a sunny rockery. *I. correaefolia* has prominent foliage and large white flowers, blooms late in May, and does well in any sunny position. All the foregoing may be propagated from cuttings. I suppose the annual Candytuft is known to almost everyone who has a garden, as it is a familiar plant for edgings, and in country gardens one sees patches of it in the borders. The dwarf sorts are best for edgings and narrow borders. Seed should be sown in sheltered positions, for early flowering, in the autumn, but comparatively few sow before spring, and, if rich soil is prepared for them, one gets a good show before the end of the summer. I would not hesitate to sow now for an early autumn display.—W. F. D.

Polyanthuses in flower.—These have been unusually fine these past few weeks, and in borders and flower beds afforded bright effects as well as sweet flowers for cutting. Much the finest display, however, that has come under my notice is in the gardens of Forde Abbey. Both in point of variety, rare colours, good habit, and beauty, this collection would be hard to excel. They have been selected annually for a long time, though there is still work for the florist in hope of further developments. All the colours known to the Polyanthus family are here, and many, certainly, far from common. The best are every year lifted, placed in pots, and their seed carefully saved and put by for August sowing. The Polyanthus is an old-fashioned flower, and cherished by thousands from the palace down to the humblest cottage garden, but the comparison of present and past strains is scarcely worth one's while to attempt to describe. In the hands of a few enthusiasts they make rapid strides in progress, and I should say without hesitation that Mr. J. Crook has a selection that will compare with the very best. This he has developed over a long course of years from his own and purchased stock. Those inclined to take up their culture are advised to commence with a good strain obtained from a reliable source.—W.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Miss M. Vaughan, Whittington Lodge, Worcester, for *Arabis alba*; 2, Mr. W. Johnson, Trafford Hall, Chester, for *Spiraea japonica* in full flower in compact.

ARTISTIC GARDEN ARRANGEMENT.

On entering a garden it is always easy to see if the owner is alive to the artistic capacities of his ground, be they large or small, or if his ideas do not rise above the possibilities of geometrically-shaped plots of bedding plants in crude, flat colours and such-like artificialities. Of late years one has been enabled, through the instrumentality of a certain weekly illustrated paper, to become acquainted with many of the features of some of the larger gardens in England. I imagine that until they had studied these illustrations few had any idea of the extent to which the formal bedding-out system still obtained in the land. The probable reason for this state of affairs is that the owners of these gardens know little of, and care less for, flowers. They have been accustomed, at certain seasons of the year, to brilliant scarlet, yellow, and blue in the beds, and desire no change. In such a case it is naturally out of the question to expect that the paid head of the gardens should substitute for a system approved of, or at least acquiesced in, by the employer, another which he might not appreciate. In the south-west, especially in Cornwall, a vastly better method of gardening prevails, for there almost every proprietor is himself or herself an enthusiastic lover of flowers. In many large gardens not a bedding plant is to be found, and where they are planted they are utilised, not in pattern beds, but to give a note of high colour where this is artistically desirable. The smallest as well as the largest garden gives ample scope for artistic feeling, and the lover of the beautiful in Nature may find much to delight him in a few square yards of ground happily laid out, while acres of bedding plants, clipped Yews, and statuary will only create in him a feeling of repulsion—and yet the former may have cost but a few shillings, and the latter thousands of pounds. The accompanying illustration shows a small portion of ground, the treatment of which could scarcely be bettered. It is quite possible to imagine that the picture represents a tiny garden in its entirety, yet if this were the case how few owners would treat it in the same manner! There would probably be a greater striving after effect, which, in a small plot, is an error. Colour is not present, and in all probability never will be, in photographs; form only is apparent, and in the picture before us we see natural beauty of form of a very high order. The light shines brightly on the rough steps in the background. They are three irregularly-shaped blocks of flat stone, not set in a direct perpendicular line, the middle one jutting out to the left of the lower, and the highest to the right of both the others. Imagine the difference of effect if these three steps had been neatly squared and set in a straight line exactly above one another! The picture would have been absolutely spoiled even had all the other accessories remained the same. The low-growing plants that spread about the base and sides of the steps and veil their points of juncture with the ground give a valuable hint of the right way to plant the edges of a rise in the rock garden from a lower level to a higher, while the tall German Flag that stands below and a little to one side of the lowest step

is just the right plant for the position, its upright lines of growth counteracting the horizontal lines of the steps, and creating balance in the picture. In the immediate foreground the nearer Iris is much benefited, from a pictorial point of view, by the dwarf flowering plant that veils its base. Good pictures, such as this, should be of inestimable value to amateurs in the laying out of different portions of their gardens. S. W. F.

CHRYSANTHEMUMS.

CULTURAL NOTES.

If the plants have not been shifted into the largest size pots they are to occupy this should be no longer delayed. At this time of the year the growth is very rapid, and a check at the

In rows they may be properly fastened by fixing posts and wire of sufficient strength. It is well to attend to this early in the season, as later, when the stems and leaves have considerable weight, a great amount of damage may be done by wind. When tied to stout wires, each plant staked separately with a strong cane, rough weather gives but little anxiety.

WATERING is another part of culture that must have at least daily attention. We sometimes read, and it is a general idea, that Chrysanthemums must have any amount of water. This is wrong, for although when in full growth they require a considerable quantity to support the abundance of leaves, they are, nevertheless, readily killed by too much moisture at the roots. It is rather difficult to say how often Chrysanthemums may be watered; but one can give some idea by describing my own practice. After any re-

potting the pots are stood close together for a couple of weeks or so. During this time sprinkling with water overhead is done each afternoon, and if the leaves of any plant show signs of flagging, then it has a good supply, enough to properly soak the ball of earth. But when the pots are placed in their permanent quarters, and stood apart as indicated above, with the full sun shining on them all day, water is more often necessary. I do not continue sprinkling overhead, but from this time carefully watch the roots. It is well to go over the collection morning and afternoon, for to give all water at one time is courting defeat. Those dry in the morning are watered and the pots filled, so that there is no mistake about the earth being moistened; the plants not requiring any then are seen to in the afternoon. This being done regularly and by the same hands, one gets to know almost by instinct when to water each plant. If there is a doubt tap the pot with the knuckles, and if a hollow sound goes out give water; if a dull sound, let that particular pot wait. There is no need for stimulants until the earth that was used in the final potting can have time to be well filled with roots, and that is not yet.

TRAINING the plants for giving large blooms is simply limiting the number of shoots. Three to each plant are accepted as the number of flowers the same will perfect when the cuttings have been rooted early and grown well by being duly shifted on into larger pots.

Late-struck cuttings bear but one big bloom; therefore we must confine the plant to a single stem. The three in the first case may be trained by loosely lopping each to the stick placed to train the main stem to. All other side growths are removed as superfluous when small. It is different with bush plants, of course. These are topped, but the last topping of the growths should take place this month (July). Afterwards securely tie the stems when required.

FLOWER-BUDS, too, should have attention this month. One reads a good deal of crown and second crown-buds in the spring. These buds will soon appear, but it is safe to remove them in July, except in the case of two varieties, Mrs. H. Weeks and Florence Molyneux. Forward plants may give flower-buds thus early, and these must be secured by rubbing out the tiny leaf-growths that surround them. But in a general way, flower-buds which form in July

An artistic garden arrangement. From a photograph by Miss Willmott.

roots is not advisable. Pots 10 inches in diameter are used for the largest and strongest plants; those an inch less for the weaker ones intended to carry exhibition blooms or to make good-sized bushes. For late-struck plants to perfect one big bloom only, or for the purpose of growing into smaller plants for decoration, I employ pots still smaller. My Chrysanthemums have been potted about three weeks, and I am giving them ample room. This is a matter of the greatest importance, and one that is often badly managed. In some cases the space at disposal is limited perhaps, but to grow this plant well air and light are absolutely necessary. If they are stood together, the pots touching each other, one gets a soft, sappy growth that easily becomes a prey to mildew in the first place, and never has the substance to develop good blooms. For container plants are stood in rows 5 feet apart, and each pot a foot from its neighbour.

do not produce good blooms. That fine variety *Mme. Carnot* and its sports, *Mrs. W. Mease* and *G. J. Warren*, are again troublesome. I daresay many readers find it difficult to keep the leaves healthy. However careful one may be, nothing seems to stop the leaves turning yellow. They are fortunately the lower leaves, and this habit does not appear to hurt the plants in the way of preventing fine flowers, as the later growth is healthy enough. The time is not far distant when the introduction of better growing kinds will oust these uncertain ones out of cultivation. The proper way to grow the

OUTDOOR CHRYSANTHEMUMS is not to interfere with the natural growth by topping. The plants assume a lushy habit, but if topped we have noticed the shoots grow irregularly. These sorts, again, may not be dishabited. They perfect a number of flowers better than they do a few. Removing very thickly placed flower-buds may do good, but to limit the blooms in the same way as other classes are grown is not followed with success. Now that they are in full growth these plants will be assisted by supplies of manure-water. Fortunately, this summer is not so dry as late seasons have been, and the chances are we shall have a fine display of these useful flowers. H. S.

NOTES AND REPLIES.

Pompon Chrysanthemums—early-flowering sorts.—A few days since, in the course of a conversation with one of our leading Chrysanthemum growers, it was mentioned that there had been less demand than usual for the early-flowering Pompon Chrysanthemums. It is difficult to understand why this is so, seeing that the early-flowering Pompons are ideal for outdoor displays. These plants in most instances have a capital dwarf and sturdy habit, and their constitution is certainly most robust. Added to these excellent traits, their free-flowering character, and also a pleasing variation in their range of colour, fit them for outdoor beds and borders. The Pompon flowers, too, have the advantage of standing well in wet weather, their petals appearing to resist damage in this way. In endeavouring to trace the reason for this seeming decline in popularity of the Pompon sorts, there is good cause for believing it to be due to the immense increase in the number of Japanese varieties now catalogued and continuously increased. It must be admitted that the variety, both in form and colour, in the Japanese sorts is great, and their curious forms have done much to enhance their reputation. The Pompons, however, can ill be spared, and all lovers of the hardy flower garden should include them in their next season's display. Even at this late period small pieces may be planted with every prospect of developing useful plants before the flowering season comes round.—E. G.

Artificial manures for Chrysanthemums.—Would you please give in an early issue of your valuable paper a few hints about the best kinds of artificial manures for exhibition Chrysanthemums, and say which of the varieties on attached list require strong, weak, or moderate feeding?—*ASTORIA.*

[Peruvian guano is an excellent fertiliser. It has an advantage over many manures in that there is no difficulty in mixing it with water. An ounce to a gallon of water may be termed a liberal quantity, and half an ounce a moderate one. If this be applied twice a week your Chrysanthemums should be much benefited. It is not desirable, however, to use fertilisers until the pots are well filled with roots. About the end of July one may expect the plants to be in the condition to require some assistance—that is, if they have been duly potted into larger pots. Most growers favour other manures used in a liquid state, to be used alternately with what are termed "artificials." Sheep and cow manure are first-rate used separately or together. The best plan with these is to fill a bag and put this in a tub of water, renewing the contents, say, every fortnight. There is not much danger in employing such liquid too strong, still it is well to dilute it to a quarter its natural strength and use it often. The guano and the liquid named are easily obtainable, and are all that is required. The former may be had from any specialist in Chrysanthemums. *Edwin Molyneux, Mrs. Barkley, M. Chenon, J. G. Lord Ludlow, Mrs. Bryant, Mr. C. C. Carr,*

ton, Miss Nellie Pockett, Mrs. Coombes, Millicent Richardson, and Le Grand Dragon require liberal feeding, while *Emily Silsbury, Calvat 99, Calvat's Sun, and Mrs. J. Lewis* must be fed moderately. We hope to refer to this more fully in a coming issue.]

INDOOR PLANTS.

STEPHANOTIS FLORIBUNDA UNDER COOL TREATMENT.

This lovely warm house climber is a general favourite, but many are deterred from growing it for two reasons, some under the impression that it needs great heat, and others because it is so liable to be infested with insects, such as mealy-bug, etc. I am aware it will bear strong heat and do well if exposed to light and air, while I am convinced that a large number of the plants that are found in many private gardens that do not bloom satisfactorily fail from being grown in great heat and shade. It may be grown in a much lower temperature than many think and bloom abundantly. Some of the best bloomed plants I ever have seen have had a temperature of from 40 degs. to 50 degs. at night during the winter season. In proof of this, early in June I saw a fine plant in Montacute House, near Yeovil, a mass of bloom, and I was told that even on cold nights in winter the temperature fell below 45 degs. But for all this I never have seen a plant more freely bloomed. It was growing on wires over the path of a three-quarter span house, and not allowed to hang over the bed other plants were growing on. In this way it can be kept free from insects by applying some good insecticide with the syringe, thus saving much trouble in sponging, etc. Nor was this a small plant, seeing it grew the whole length of the house—50 feet—and was trained on three wires. Some side shoots put out from the main shoot had twelve trusses on them in a foot length. The roots are allowed to run at will in a bed in the house, on which are growing various warm-house plants in pots. No doubt most of the water it receives is from the drainings of these plants. It was growing near the glass. In summer the house is shut up with abundance of sun-heat. No better position can be found for it when planted out than this, seeing it gets strong light and does not shade other things. Many amateurs and small growers could readily grow it on the cool system, and when grown in pots I have always found it bloom satisfactorily. It must be well ripened in winter, keeping it on the dry side. Sometimes the *Stephanotis* is met with full of bloom in small pots. Some imagine this is a special kind; but take off good ripened shoots, root them quickly, and they will bloom in this way. J. CROOK.

CINERARIAS.

The time for sowing is from March to June, according to the season at which they are wanted in flower. Those got up during March come in during winter, and the others follow on till quite late in spring. The way to induce the seed to germinate freely is to well drain a pan, and then fill it with finely-sifted, rich, light soil, which should be pressed quite firm and level on the surface, when, after being watered, the seed may be sown, just covered lightly, and after this is done have a pane of glass placed over the top. If the pan is then placed in a warm pit or frame the young plants will soon make their appearance, when the glass should be tilted to prevent damping, and in a day or two removed altogether. As soon as the plants are large enough to handle they may either be pricked off into shallow boxes or potted singly in small pots, the latter being the better plan, as then they grow right on without further check.

To encourage growth, it is necessary to keep them a little close for a time and gently syringed every day, and when they have become established they should have more air, and be shifted on into larger pots as required, after which the best position for them is a pit or frame facing north, where they should be stood on a hard coal-ash bottom, which will prevent worms getting up into the balls, and remain damp and cool under the glass. The

is a great point towards their successful cultivation, as unless a moist atmosphere surrounds them they are apt to get red-spider or thrips—insects that soon disfigure and spoil them, as does also green-fly, to which *Cinerarias* are very subject; but they may easily be freed from these latter parasites by fumigating, which requires care, as the plants are very tender in the leaf, and will not bear much smoke at a time. This being so, the safest way is to fumigate slightly each night and morning for two or three days, after which the plants should have a good syringing to wash off any straggling insect or deposit left from the smoke and make them quite clean. Should mildew attack them, the best remedy is to boil a pound of sulphur in 2 gallons of water, and syringe them with it when the water is cold and clear; this will destroy the fungus without injuring the foliage in the slightest degree. The most suitable soil for growing *Cinerarias* is a light, fibrous loam, which should be made rich by working into it some rotten manure from cows or sheep, and if a slight sprinkling of soot be added as well, the leaves of the plants will be greatly improved in texture and colour.

NOTES AND REPLIES.

Twelve good Pelargoniums.—I notice in *GARDENING ILLUSTRATED* for July 5 mention is made of two *Ceraniums*—viz., *Rudyard Kipling* and *de Maclaren*. I should be very glad if some reader of *GARDENING ILLUSTRATED* would name ten others such as good as these two, as I should like to form a small collection.—*ESSEX.*

[Equal to the two named in size and substance of bloom, and embracing a wide range of colouring, are: *Chaucer, Enid, Killy, Majestic, Mary Beton, Mrs. Pobe South, Nicholas II., Phyllis, The Mikado, and The Sirdar.*]

The Throat-wort (*Trachelium caeruleum* (A. B. C.)).—This is the name of the plant you sent. It is easily propagated in the spring from cuttings taken from the base close to the soil, some of these possibly having roots of their own. Such plants will flower the same season in 6-inch pots, being afterwards kept to grow on the following spring, so as to provide, if need be, a set of larger plants. Seedlings can also be easily raised, but when this plan is adopted the seed should be saved and sown as soon as it is ripe from plants that have flowered early in August. The seedlings can then be kept in a box or pan in a cool greenhouse during the winter. It is not necessary to devote house room to it from the end of March until the flowering season comes round. The plant will do good service at a season when any novelty is a pleasing change. The best trusses of violet-blue flowers are produced on the terminals, but the lateral shoots on strong plants are also very effective. The best soil is loam and leaf-mould, with a little sand, potting being done very firmly.

Camellias.—These will in most cases have now completed their growth, although the hardening process through which the foliage has to pass may not be finished. The syringe should be freely used, and where possible a moist atmosphere still maintained, both tending, in conjunction with plenty of moisture in the soil, to renewed root action, which hardly keeps pace with the rapid development of the leaf growth when once it starts. Slight shading is advisable. As soon as the foliage is hardened (this in the case of early flowered plants will soon be the case), then the repotting or retubbing of any in need of this should have attention. I consider this to be the best time to do it, having frequently noted how very active the roots are during the summer. For this purpose, as regards soil, some prefer peat, others loam. In my own case I give a mixture of the two in about equal parts; this prevents the souring of the former and the adhesiveness of the latter. Lime rubble is a good addition when crushed down fairly fine, or some bone meal may be safely used. Plants that are moved out-of-doors for the summer season should until the growth be hardened still have a slight protection. Where planted out in borders, a good mulching of such as the manure from a spent Mushroom-bed or a top-dressing of good soil to remain permanently moist will probably be found a great assistance in

TREES AND SHRUBS.

THE MEXICAN ORANGE-FLOWER IN CUMBERLAND.

THERE was an illustration in GARDENING ILLUSTRATED of May 24th of the Mexican Orange-flower (*Choisya ternata*) in a Devonshire garden. The illustration to-day shows how the plant grows in a Cumberland garden. A quantity of flowers had been cut for the house before it occurred to me to photograph the plant. It flowers twice a year, the second time in November, of course, not so profusely. It has never been covered up, thus showing how hardy it is. l. E. R.
Newton, Ravensglass, Carnforth.

NOTES AND REPLIES.

Dwarf Honeysuckles.—On page 182 Mr. Groom advises the growth of Honey-

root. The frost of the past winter would have played havoc with many of the cuttings had not the ground been well trodden after the frost had lifted and the soil become dry enough to allow of it being done.—W.

White Wistaria in bloom near Aberdeen.—There is a plant of the white Wistaria in flower here in the open air against the wall of the house. As I have never heard of this plant flowering so far north, I write to ask if any of your readers know of such a case? The plant has had no protection whatever during the winter, and is now in flower and growing rapidly. The house and garden face south, and are well sheltered from the east, and I think the flowering of the plant proves that this is a favoured spot.—*Gordon Baxter, Gardener, Caskieben, Kinaldie, Aberdeenshire.*

[We know well the garden referred to, which, as the crow flies, would be about eight miles from the sea, and are not at all surprised that the Wistaria is doing well there. The house on which it grows lies very high, the ground sloping to the south, the drainage in consequence being good, whilst it is also very sheltered from the north. There are many fine

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

Mint falling.—Will you kindly tell me the cause of and how to remedy the disease on the sample of Mint enclosed, which I obtained from a nurseryman when it was in a dormant state? I planted it in good soil during February. I enclose you a sample of its growth, which I think is infested with some kind of canker or fungoid growth.—A. B. C.

[Your Mint is attacked by the Mint Cluster-cup fungus (*Puccinia menthae*). We are afraid there is no cure for it, as the fungus is in the stems, in the lower part of which it passes the winter. The best thing to do is to pull up the plants at once and burn them, planting some Mint from an uninfested source in another part of the garden.]

Chlorhydric acid.—Will you kindly tell me what chlorhydric acid is that a correspondent, in your issue of the 6th inst., recommends as a cure for canker in fruit-trees? I should like to try it, but neither of the chemists I have asked for it recognises it under that name.—K. E. J.

[As far as I know, there is no such thing as "chlorhydric acid." It has been suggested to me by a lecturer on chemistry that hydrochloric acid, or muriatic acid as it is often called, is what is meant. This acid would certainly destroy any fungus or vegetable tissues with which it came into contact, but if the mycelium or spawn of the fungus has thoroughly established itself in the branch, though destroyed at the part where the acid is applied a canker will appear in some other part of the branch. This, of course, would be the case whatever means are used to destroy the fungus short of cutting off the branch. Great care should be taken when using hydrochloric acid not to allow any to get on the hands or clothes, as it is a most corrosive fluid.—G. S. S.]

Gnats in the garden.—Could you kindly name the enclosed for me? It is a perfect pest, driving everyone from my garden as soon as it begins to get dusk. Its bite is severe, leaving much inflammation behind. I do not know if it will lose colour in drying, but, when fresh, the body is about the size of a pin, and is banded with black and yellow; head, thorax, and legs black.—*IGNORAMUS.*

[The insect you sent is a specimen of one of our many species of gnats, and belongs to the genus *Culex*. I do not know its specific name, but I could obtain it if it is a matter of importance, and will do so with pleasure if you desire to know it. These insects lay their eggs in stagnant water, and the grubs or larvae pass their existence in the water. Apparently the only way of destroying these insects in ponds, etc., is by pouring a little paraffin-oil on the water; this forms a slight film on the surface, which prevents the larvae from obtaining any air when they come to the surface, as they frequently have to do for that purpose. It is a curious fact that it is only the females that are able to bite, the mouth organs of the male being in such a rudimentary condition that it is questionable whether they are able to feed at all. This peculiarity occurs in some other insects also.—G. S. S.]

The Asparagus-beetle.—Can you kindly tell me the name of the beetle in the enclosed glass tubes? I send eggs, larvae, and full-grown insect. They swarm on Asparagus in my garden, but feed on the foliage, and do not seem to have damaged the young shoots. Are they injurious to the plant? And, if so, how can I get rid of them? I shall be grateful for a reply in an early number.—H. E. Fox (Rav.).

—Kindly tell me what the enclosed caterpillar is on Asparagus, and how to treat plants? They are infested and lying from the plague. Never seen here before.—*BOLNEY.*

[The insect infesting your Asparagus plants is the Asparagus beetle (*Crioceris asparagi*), and is, unfortunately, a very common pest. The beetles may be found on the plants from April to September, during which time there are probably two or more generations, but it is difficult to ascertain this with any certainty, as beetles, grubs, and eggs may all be found on the plants at the same time. The beetles fall to the ground at the slightest alarm, but many may be caught by shaking the "grass" over an open umbrella. As soon as cutting is finished for the season the plants may be sprayed with Paris green, paraffin emulsion, or any of the insecticides which contain soft-soap. Though this insect is not the cause of so much injury to the Asparagus crop as it is in France, it at times does much damage by destroying the "grass" which, of course, weakens the plants for the next season.—G. S. S.]

The Mexican Orange-flower (*Choisya ternata*) in a Cumberland garden. From a photograph sent by Miss Ramsden, Newton, Ravensglass, Carnforth.

suckles in pots, and certainly, where the means for doing so is available, nothing better could well be had. Last summer I saw some such Honeysuckles, not in pots, but growing along the edge of the vegetable quarters of a small garden, which greatly interested me. These were kept to a height of from 18 inches to 2 feet, and formed neat little bushes by frequent pinching of the summer shoots. These were, I believe, of the Dutch variety mentioned by Mr. Groom, and, I am told, were almost continually in flower during the summer and autumn months. They are raised from cuttings fairly easily, choosing shoots about a foot long, in the autumn, taken off with a heel of older wood attached. When putting in the cuttings, the soil should be made quite firm, and, should frost loosen the ground in winter, choose a dry day to make the soil about them firm again by treading. Cuttings must be kept firmly fixed in the ground, otherwise a goodly proportion of them will fall to

specimens of conifers in the garden, while in one part there are, or were, some fine trees of the common Beech. There used to be, too, a very fine specimen of the Monkey Puzzle (*Araucaria imbricata*), the branches sweeping the ground on all sides. *Eucallonia macrantha*, planted on the house, used to grow and flower freely, and the common Hop trained to a high pole made enormous growth every year. The Pampas Grass, growing in the kitchen garden, yearly produced its handsome heads of bloom. The kitchen garden, round which is a fine old wall, slopes to the south, and here Strawberries and all small fruits, including cordon-Gooseberries, used to be excellent. Raspberries planted for nearly thirty years used to throw up canes 5 feet and 6 feet high, and bear heavy crops of fruit. In the vicinity of the house are the remains of an old Roman road, and also those of a supposed Roman camp, while near are some relics of the Druidical times, as at Stonehenge.]

VEGETABLES.

A DRY WEATHER VEGETABLE.

PERPETUAL SPINACH OR SPINACH-BEET.

THIS is a most excellent and useful vegetable, which can be had all the year round by making sowings at three different times—one in April, one in July, and another in September—devoting ground to it according to the demand. The Perpetual Spinach seems to grow luxuriantly in any soil, and at all seasons of the year, and being a gross feeder one can give the plants a good quantity of liquid or other manure. Often in very hot, dry weather the Round-leaved or Summer Spinach is liable to run early to seed; therefore it produces but few leaves, and these only of second quality. The Perpetual sort, on the contrary, grows well in hot weather; and by feeding the plants freely with artificial manure one is able to get from the spring (April) sowing alone a good supply during the summer and autumn. The second sowing must be made early in July, in order to give the plants time to get well established before winter, and from this one a good supply is obtained, in proportion to the size of the piece of ground devoted to the crop. The September-sown lot comes in well in early spring. This Spinach is exceedingly hardy, and often, when the ordinary Prickly-seeded Winter Spinach is killed, it survives the frost unscathed.

CULTURE.—The ground for this Spinach should be either dug deeply or, better still, trenched, working into it at the same time plenty of rotten-manure for the roots to feed upon. The seed may be sown broadcast upon the beds or in rows, as they afford a better opportunity for keeping the ground free from weeds, and, if need be, artificial manure can be sown between the rows, hoeing it in deeply with a draw hoe. Bone meal is one of the best manures for Spinach; it seems to invigorate the plants in a very short time after being used. Liquid-manure from the farmyard is, however, quite as good, only it requires to be oftener used during the season. I find two good dressings of bone-meal will carry a crop on for six months.

In the White-leaf or Spinach-Beet (here figured) when true, the leaves are very numerous, broad, slightly undulated, and of a very light or yellowish-green colour. The leafstalks are somewhat larger than those of Beetroot, and of a paler colour than the blade of the leaf.

SEAKALE.

I RECENTLY visited a Surrey cottager's garden of the best possible description, in which I noted a small breadth of very strong Seakale. The cottager stated that he found that plot to be relatively the most profitable area he had in the garden, as it had produced him a quantity of fine Seakale in the late winter, when all other garden crops were scarce, and this, based on the customary value of such products in the shops at that time of the year, showed that the produce was worth double that given by any other crop. The matter is easily tested by anyone willing to take the trouble to do so. He can in the winter trench 2 feet deep and well manure a plot either one half or a full rod of 30½ yards in area, then get from some grower strong Seakale root cuttings properly made and about 5 inches long. Dibble those into rows 20 inches apart and 15 inches apart in the rows, just allowing the tops of the root cuttings to be covered with fine soil. That will require just about 108 cuttings to a rod, each one, assuming that proper growth was made, giving a strong blanched head the following winter. If these heads were sold in bundles of nine for 1s. each, that would give a rate of 12s. per rod, and a capital return it would be also. But Seakale is a valuable vegetable, equally to grow for own home consumption as for sale, and should be priced on the same scale. Blanching is easy. In the late autumn leafage dies away, and there remain but the buried roots and the purple crowns, which just project from them. To blanch well, it is advisable to save dry all coal ashes made, and

screened, then to place these in ridges along over the rows, and on these some of the soil, well forked over and made as fine as possible. These ridges of ashes and soil should be fully 8 inches to 9 inches deep. Cutting may begin at one end of the earliest covered rows so soon as the sides of the ridges of soil are seen to crack, and may be continued as needed until all the blanched Kale has been cut, and the soil levelled. A. D.

NOTES AND REPLIES.

Tomatoes falling to set.—I have six Tomato-plants, and not one has fruited. The flowers all drop. I have watered with liquid-manure, also soot-water, and top-dressed with manure from yard. I have two plants in one bucket. Will that prevent bearing? Some I have placed outside, but it seems to make no difference. If you can give me any help, I shall feel obliged.—Miss I. HORSBET.

[You have made a mistake in feeding before the fruits have set, thus causing the growth to be too strong and vigorous, and responsible for the flowers dropping. Never feed Tomatoes until the crop has set, and see that all the side shoots are rubbed out so as to admit light and air to the flowers.]

A good Pea.—For several years I have grown Senator Pea, but it seems never to have been tried at Chiswick. There is a big trial of Peas there this season, and amongst it is Senator. It is of medium height, averaging

A good dry weather vegetable (Spinach-Beet).

3 feet, and is a splendid cropper. So pleased were the members of the fruit and vegetable committee with it the other day that they at once gave it the high award of a first-class certificate. I have Senator growing on some manure trial plots at Surbiton. There are seven rows, one on each plot, and although lying as in field culture, the crop is one of the heaviest I have ever seen. The pods are long, curved, fully filled, and the Peas soft and sugary. I regard it as one of the best 3-foot Peas in cultivation. The good old Daisy, from Messrs. J. Carter and Co., also obtained a first-class certificate. Dwarf Harbinger, Little Marvel, and Early Giant (4 feet), from Messrs. Sutton and Sons, and Western Express (5 feet), R. Veitch and Sons, obtained awards of merit. —A. D.

Vegetables at the Holland Park Show.—Remembering how very important is in any garden the vegetable department, it was somewhat a matter for surprise and regret that so few vegetables should have been sent to the flower show recently held in Holland Park, Kensington. But whilst all descriptions of plants and of flowers were there represented almost to repletion, fruits were few and vegetables fewer. So much is unfortunate, because unless these very important features were well represented horticulture is shorn of some of its most important attributes. But for the enterprise of Messrs. Jas. Carter and Co., of Holborn, who sent a very nice collection of some twenty dishes of vegetables, chiefly, of course, grown under glass, and of Mr. S. Mortimer, who had capital Cucumbers and Tomatoes, there would have been no vegetables. Possibly it may be pleaded that the season is late: both vegetables and fruit late. That may

be so, but, on the other hand, there were far superior examples and far more of them at the Temple Show, held a month earlier, and fruit was seen there in much greater abundance. It was to be deplored that at a great metropolitan show, visited, as it doubtless was, by many foreigners and colonials, products of such great importance, and to the production of which we, as a nation are second to none other, should have been so marked by being absent. How different is the case at the myriads of small rural shows, met with all over the kingdom. At those, vegetables and fruits always occupy the most prominent positions, and are, so far as the season will allow, well represented. The complaint made with respect to the absence of vegetables at Holland Park strongly accentuates the need there is for the holding of at least one exhibition of first-class vegetables in London annually.—A. D.

Tender Cucumbers.—It is hardly too much to say that in nine cases out of ten Cucumbers are not cut until they are a long way past their best. Two-thirds grown is about the best size for Cucumbers. Beyond that stage they deteriorate. It is somewhat surprising that they should be allowed to do so; for Cucumbers are invariably sold singly, by the brace, or by number. Neither is there any loss of weight by cutting Cucumbers early. On the contrary, there is a great gain. The earlier the fruit is cut, the more will be produced and the longer the plants continue bearing. There is nothing like early cutting for perpetual fertility. Each fruit removed at one-half or three-quarter size is succeeded by two or three more. A second fruit will almost be fit to cut before the first would have been removed under ordinary circumstances. Early cutting also maintains the plants in the highest health and strength.

Vegetable Marrows.—In spite of the fact that these plants like rich soil, all the same they are impatient of over-much wet. Should the summer prove to be a cold, damp one, mildew will soon be plentiful on the plants, and then they rarely fruit well. Where growing on mounds or heaps of refuse, or trained over thick hedges or on the roofs of sheds, pig-styes, etc, the vine and leafage are usually more healthy than when lying on wet soil. Where the plants have been put out on to merely slightly elevated mounds, the vine trailing over the level ground, it will be wise at once to lay down Pea-sticks, just throwing the vine back when it is formed, and relay it over the Pea-stakes, as these will keep it off the cold ground. All the Cucurbitaceae family are very tender, and cold, wet soil or air is injurious to the plants. Whilst doing very well outdoors, Vegetable Marrows, all the same, like all the warmth that can be furnished.—A. D.

Winter Turnips.—A good supply of these is valuable during the winter and spring months. It is difficult to gauge the exact time to sow, but, making allowance for difference of climate, the main winter crop should be got in between June 20th and July 20th, sowing earliest, of course, in late districts, and later in the south and in early localities. Two sowings, however, are best, allowing a fortnight between them, and then a good standing winter crop is almost certain. Winter Turnips should not be above half grown when winter overtakes them, as they then stand frost and alternations of the weather better. Mature, full-sized roots are the first to give way. Moderately rich ground and a deep till should be afforded them; and when the plants are past all danger from fly they should be thinned out, as Turnips which are thick on the ground never stood the winter well. Some people sow a later crop between the first and last weeks of August to succeed the first, but such a crop should not be trusted to. They may form usable little hulbs in spring, but the chances are that they will never come to anything, and run to seed the first thing when growth commences. Behind a north wall is a good position for a winter crop of Turnips, as they are always in the shade during the short days, and, not being so often frozed and thawed, they last better. Chirk Castle is by far the best variety for winter, being very hardy, white-fleshed, and good.

GARDEN WORK.

Conservatory.—Summer is fast merging into autumn, and any specimen plant which is likely soon to require more root-room should have a shift now. Palms, Bamboos, Indian-rubbers, Japanese Grasses of various kinds, including the Eulalias; then among flowering plants, Acaecias, Epacrises, Heathis, Azaleas, Tree Carnations, Rhododendrons—anything, in fact, that is pinched at the roots—if repotted at once will have time to get the roots well into the new soil before the short days come. Firm potting is essential to obtain short-jointed growth. Loose potting may rush a plant on a little faster, or may appear to do so, but there is no permanency in it, and nowadays we are trying to do with smaller pots. With this object in view, firm potting of all things is absolutely necessary. The sweetest climber just now is Mandevilla suaveolens. It wants plenty of room, and flowers best when permitted to run up near the glass, or even outside at this season through the open lights. No greater mistake can be made at this season than keeping the conservatory too close, either night or day. Of course, this does not mean that the house should be open during a gale, or that if the outside temperature falls very low, as was the case here a few days ago, the house should not be nearly or even altogether closed during a cold night if necessary. In gardening there should be no cast-iron rules, and the rule of thumb man generally fails. Tree-Carnations and most of the winter-flowering just should now be in their flowering pots to get well established before winter. Of course, this does not refer to such things as Cinerarias and Primulas. Double white Primulas with us have just been divided. Many of them which had been top-dressed with sandy peat or Cocoa-fibre had made roots; but we find cuttings with a piece of old stem attached soon form roots. Formerly we used to give these cuttings heat, but now we place them in a close frame, shaded a little, ventilating a little early in the morning to keep down damp, and they root quickly and form good plants.

Stove.—Many of the stove plants, flowering and fine-foliaged, have been moved to the conservatory. Others, such as Gardenias and Francisceas, have been taken to a cool-house to ripen. Where there is a number of good specimens of Eucharis Lilies a succession of flowers may easily be had by resting in succession. I do not think it is wise to turn them outside altogether, as under such conditions the plants sometimes lose most of the foliage, and that is not natural and weakens the growth. When the constitution is weakened the mites come on or disease makes its appearance. In plant growing either indoors or outside anything which is calculated to lower the vitality of the plants should be avoided, or trouble will surely come. Mealy-bug should be looked after now. Thrips also may appear on Crotons and Dracenas, and be unobserved during a quiet time. For insects generally there is no better remedy than the vaporiser, but I do not think it will clear out mealy-bug, red-spider, or scale. If a plant is badly infested with mealy-bug or scale the best and cheapest remedy is to throw it on the fire. Plants are so cheap now and so easily increased that I should never waste time over unhealthy ones.

Ferns under glass.—All the young stuff will do better in low pits or frames than in a house for the next two or three months. The glass must be lightly shaded in some way. Linewash, with about a pound of size mixed in each pailful, will do, or Summer Cloud may be used. Ventilation must be freely given at the back during the day. Clearing the Fern-houses of the young stuff will give more room to the larger plants, and so all will benefit. The best time for propagating these species and varieties which do not produce spores freely is in the spring, when the growth is just becoming active, though, of course, the propagation of choice kinds may go on all through the season if necessary. I suppose no one has two any of the best of all the Maiden-hairs, A. Farleyense, and to work up a strong stock quickly it is better to divide young plants than old ones. Nephrolepis exaltata is one of the best basket Ferns. Its growth is very free,

and young offsets soon accumulate round the base, which may be removed with a sharp knife without detriment to the main plants, and in this way a stock is soon worked up. Tree-Ferns of large size are hardly so common as they were. Anyone having an old dead trunk of a Dickeonia may soon furnish it with a young plant of Woodwardia radicans planted in the top, where it will soon form a drooping head of fronds that will give the appearance of a veritable Tree-Fern. Ferns will require a good deal of water now, and the atmosphere must be reasonably moist by damping floors several times during bright days. Fires will not be required now.

Watering Melons.—Keep the water-pot away from the main stem. The principal feeding roots are not there, and if water lodges there canker may be troublesome if the weather should be damp and cold. Ventilate freely in bright weather to get the foliage firm and vigorous. Red-spider seldom attacks hard, leathery foliage. Give liquid-manure when the fruits are swelling twice a week if water is required so often. No shade should be given to Melons. Elevate the fruits on panes of glass to lift them off the ground. If the fruit cracks, the ventilation has been at fault, especially in the morning, or probably too much water has been given. Discontinue watering when the fruits begin to ripen and give air very freely.

Window gardening.—The most useful window plants now are Begonias, Musk Balsams, Plumbago capensis, Campanulas, various kinds. C. garganica is a charming plant for basket or in a pot for a bracket, and is now nicely in flower. The old-fashioned double-flowered Myrtle is now in flower and makes an excellent plant for the hall or the porch outside. Many amateurs grow Lilies, especially the lancifolium section, which may be grown from year to year.

Outdoor garden.—If the seed-pods are removed from Sweet Peas, a successional lot of flowers will be produced. The same thing occurs with Canterbury Bells, Antirrhinums, and many other things. The Antirrhinums are exceedingly effective in masses. For this purpose soft colours are best, and, if the seeds are saved from isolated groups, they come true to name, especially the white, crimson, and yellow kinds. The weather is too hot and dry yet for budding, but as soon as the change comes the standard Briers should be done. The dwarfs may wait a bit, as it is generally possible to find moist bark by removing a little soil from the base, and the lower the bud is inserted the better. The propagation of Carnations and Pinks may be done now. Place mounds of gritty soil round each plant for the layers to root into. This makes sure work if the soil is kept moist. Pinks are usually propagated by cuttings or pipings, or they may be layered like Carnations. All the Dianthus family, including Sweet Williams, if there is anything very choice, may be increased by layers. Faded flowers should be removed from Roses. A soaking or two of liquid-manure will help the later blooms. To obtain fine blooms of Asters and Stocks, the plants must be well nourished with liquid-manure, and the blossoms should be thinned, if required for exhibition, and shaded as the flowers expand. The same remark applies to most flowers grown for show.

Fruit garden.—The red-spider is a very small insect, but a very troublesome one when it gains a footing under glass. In some gardens it gives more trouble than in others. I once knew a garden on elevated ground, and where the soil was light, where it was next to impossible to get rid of it altogether. But usually where the roots are kept healthily moist, the ventilation properly managed, and the syringe is in good and careful hands, the red-spider need occasion no alarm. A low temperature may kill the perfect insect, but will not injure the eggs, and this is where the value of a thorough winter cleaning of vinerias and Peach-houses comes in, especially where there has been red-spider or mildew in previous years. To give colour to Peaches and Nectarines the fruit must be exposed to light and sunshine, and all foliage which unduly shades fruits should be thrust on one side or removed altogether, but the foliage is necessary to the

proper ripening of the fruit, only a very limited number of leaves should be removed at this season. It is pretty generally understood that when most fruits are approaching the ripening stage the supply of water is reduced, and this is where the value of experience and judgment comes in. Too much moisture in the soil spoils the flavour, and too little may lead to shrinkage in the size of the fruit.

Vegetable garden.—Sow Lettuces of hardy kinds freely. Cabbages also of early kinds must be got in. No one should trust to one sowing of early Cabbage, nor yet to one kind. Most vegetable growers have their favourite kinds, but a good deal depends upon the selection of the stock, and this means that seed should be obtained from reliable people, and in this case we may safely take what they recommend. Personally, I am growing Ellam's Early and a good stock of Enfield Market Cabbages. For Lettuces for late autumn and winter, of course, one grows the black seeded Bath or Brown Cos, and if a white Lettuce be wanted, Hicks' Hardy White will do. All the Year Round Cabbage Lettuce is hardy, and Wheeler's Tom Thumb Cabbage Lettuce is excellent for sowing under glass for winter, and for forcing, Paris Market is a good Lettuce. The Peas which are mulched will pass through the hot bursts of sunshine without much injury, or much labour in watering. Keep the hoe going. This always pays at this season. Follow up the early Potatoes with another crop. There are several things which must be sown shortly, including Turnips, Winter Onions, and Spinach. There is, of course, time enough, but the land will want a top-dressing of something, and time afterwards to settle. Earth up all green crops as they advance in growth. E. HUBBARD.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 28th.—Attention is now being given to budding Roses and fruit-trees at every favourable opportunity. The layering of Carnations and Picotees is also being attended to. A few seed-pods will be saved from plants in pots. I feel an interest in this work. It has future possibilities, even if no great success has been had up to the present. Sowed more Green Curled and Batavian Endive.

July 29th.—Planted more red Celery in trenches. The plants are shaded for a time by laying branches from trees across the trenches. Sowed Spinach. Very often this sowing turns out well, though occasionally a few of the plants may bolt. These, however, are easily pulled up. Lifted Shallots and Garlic and laid out to barvest. Tomatoes are receiving a good deal of attention now in thinning and tying. A loose surface is kept where mulch cannot be given.

July 30th.—Sowed seeds of Humea elegans. This is a very useful old plant either for conservatory or planting outside. This was formerly used largely in terrace gardens. Whitewashed and cleaned thoroughly Mushroom-house ready for the autumn and winter beds towards the end of next month. At present Mushrooms are obtained from outside beds, and beds made up outside now in the shade of a wall will be useful through the autumn.

July 31st.—Planted Lettuces and Endives on ridges between Celery trenches. These generally do well, showing the value of depth of soil. Some trouble has been experienced with the black-fly on Morello Cherries, but we have at last got rid of it, chiefly by dipping the shoots in a mixture of Tobacco-powder and soft-soap. The powder is just as effective as Tobacco liquor. Strawberry runners laid in small pots are removed from time to time as soon as rooted, and in the course of a few days are shifted on into fruiting pots, and placed thinly on coal-ash beds.

August 1st.—Made a last sowing of Cabbage seeds, including a few seeds of the Blood-red for pickling. Dahlias are looked over now to tie and thin growth. Layered shoots of Daphne Cneorum in border. Evergreen and other hedges have been trimmed. Sowed French Beans of an early kind in pit for late harvest. (Will be kept off for some time.)

Some time is given to the Chrysanthemums, removing side shoots and killing earwigs.

August 2nd.—Late Grapes are looked over every week to regulate lateral growth. Peaches everywhere are exposed to sunshine by thrusting aside or removing foliage if necessary. Some of the late Plums have been removed from orchard-house and plunged outside to give more room to late Peaches and Nectarines. The Plums do well outside after June. Conservatory is rearranged weekly, and anything fresh available obtained from stove or other houses.

BIRDS.

Birds dying (Zitella).—We can only repeat that the cause of the death of so many of your birds is the direct rays of the sun playing on them, and thus causing heat apoplexy. Unless you shade the aviary, your birds will, we fear, continue to die.

Death of Canary (Ethel Marjory Hunter).—The bird was in an advanced state of decomposition, and, therefore, an examination could not be made. There is no doubt, however, from the particulars you furnish, that surfeit was the immediate cause of death, brought about through partaking too freely of the egg-food supplied for the feeding of the young. You did right in giving castor-oil, the bird being so constipated. A teaspoonful of liquid magnesia in an ounce of the drinking water is also useful in cases of this kind. Feeding on too rich a diet often ends in mortification of the bowels in cage-birds. The abdomen becomes puffy and assumes a dark appearance, and having reached this stage there is no cure. It is a very difficult matter to prevent the parent birds consuming too large a quantity of egg-food while feeding their young.—S. S. G.

LAW AND CUSTOM.

A jobbing gardener's charges.—I am a jobbing gardener, and was sent for to mow a lawn. I took another man and a boy with me, and I was there three hours, and my man and boy were there five hours. I charged 1s. per hour for two men and a boy, and 1s. 6d. per truckload of Grass carted away. Payment for the cartage was refused, and less than I demanded was offered for the cutting of the Grass. Can I recover my charge in full?—T. M. W.

[In the absence of an express contract, a man who is employed to do any kind of work for another is entitled to reasonable remuneration, and where the person employed is ordinarily engaged at such work, the payment he usually receives for his services must be considered reasonable, and must be paid by a stranger engaging his services without making any special contract as to the amount of such remuneration. If your ordinary charge for the services of two men and a boy is 1s. per hour, you may recover that amount, and on the face of it the amount seems reasonable enough. You say your employer deducts 1s. from your charge for the time occupied in the work, but you do not state why he makes the deduction; if he has a good reason for his deduction you cannot recover, but if his only reason is that he considers 1s. an hour too much, the deduction cannot be enforced. You do not say why payment for the carting of the Grass was refused. If you were engaged to cart it away, you are entitled to be paid a reasonable sum for so doing, but if you were not engaged to cart it away, and your employer refuses payment on the ground that he did not engage you to cart it away, you cannot recover that part of your charge. More than this I cannot say, as you do not give any reason for the refusal.—K. C. T.]

Breach of contract.—Our local horticultural society were to have held their fifth annual show on Bank Holiday next and following day. For various reasons it was decided a week or two ago to abandon the show for this year. The band and tents had been engaged some little time ago, and the orders for both were at once cancelled. The tent proprietors, who were to charge £16 for the two days, now say they shall want £5 (half the charge). We consider this unreasonable. Can they compel us to pay anything? They had quite a month's notice of the abandonment.—HOLLIBOCK.

[You entered into a contract with the parties in question to provide a tent for your use on the Bank Holiday and the following day, and the contract was binding on both parties. You have now cancelled the contract, or, rather, you have given the other parties notice that you shall not fulfil the contract, and consequently you have broken the contract.]

the contract, and the proprietors of the tent are entitled to compensation for your breach of contract. The compensation to which they are entitled is the sum they will lose through your breach of contract; in other words, the profits they would have made if you had carried out your part of the contract. Whether that profit would have amounted to £8 is a doubtful matter, but if they sue, they will have to prove the amount of their loss through the breach. It may be that their loss will be merely nominal, as if, for instance, they are enabled to secure another contract for the same day, and that contract be equally remunerative. In that event the compensation would be practically confined to the expenses incurred in making the contract, etc., but it is possible that for some special reason the compensation might not be strictly limited to the loss of profit through the cancellation of the contract. It is clear that you are liable in damages, although the actual amount of damage is uncertain.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being nappies and other small pots. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Agasthea celestis (R.).—This is the name of the blue flower sent, and it is frequently called the Blue Marguerite. It is a very beautiful old plant, and may be increased by cuttings in spring. The soil should be loam and leaf-mould made sandy, and it may be planted outdoors in the summer time.

The Lion's-tail (Leonotis Leonorus) (W.). A free-growing, beautiful plant. It is easily grown, and makes a good plant for late blooming in the greenhouse; but the shoots should not be stopped after the end of the present month. Drain well, as it likes an abundance of water. Pot in good loam. Grow in the open air during summer, but do not let the plants suffer from want of water, and remove to the greenhouse towards the end of August.

Treatment of young Ferns (R.). The seedlings should now be pricked out in clumps of six to a dozen together into other pots and pans, as they are presumably too small at present to be potted separately. As they gain in strength use a little loam in the potting compost, increasing the quantity as the plants get larger for all robust kinds, as *Pteris*, etc. After each removal into larger pots they must be kept close for some days till established.

Mignonette for winter flowering (Receda). Seed of this should be sown now without delay in the pots in which the plants are to flower. Five or six-inch pots are good sizes to use. These should be drained and filled with a compost consisting of loam and a little leaf-mould, well-rotted cow-manure, and a sprinkling of sand and fine rubbish. The pots should then be placed in a cool and airy frame, and in the time be transferred to the greenhouse.

Azalea-leaves turning brown (A.). The leaves are covered with "thrips," lay the plants on their sides and well syringe them with strong Tobacco-water. Place them afterwards in a partially-shaded situation out-of-doors, syring them freely every afternoon with clean soft water, and repeat the Tobacco-water washing (placing the plants then on their sides) twice a week for two or three weeks.

Unhealthy Gloxinias (W. B.). The leaves are badly affected with "thrips," a great insect pest of Gloxinias, and generally brought about by a hot, dry atmosphere in the house, and sometimes also the plants may have been allowed to get dry at the roots. The only thing to do now is to maintain a cool, moist atmosphere around the plants, and to give very frequent light fumigations with Tobacco. These must be often repeated, or the "thrips" will not be destroyed.

Arum Lilies (Carm.). These may either be grown in pots, or be planted out during the summer, the latter method giving the finest plants. Choose a somewhat sheltered and shaded situation, and make the soil, which should be well-manured, very fine, adding to it some well-decayed manure. Pull the large plants to pieces as required, and set each one separately some 12 inches apart. Water copiously in hot weather, also sprinkling overhead frequently. Pot them up again by the beginning of September.

Ferns losing their fronds (C.).—When the fronds decay in the manner described it is a sign that the roots are unhealthy, or that the atmosphere is too damp. We should leave the top of the case off all night, and during the greater portion of the day sometimes. We do not consider *Adiantum* to be the best. Ferns for culture in a conservatory like more light than the generality of ferns do, and they dislike moisture on the fronds, which should never be wetted in watering. If the plants still refuse to thrive, we should next season replace them with other kinds.

Tuberous Begonias as basket-plants (F. P.).—Yes these do make capital basket-plants, and there are now very many excellent kinds to be had; and if treated in this manner and well managed, the large, brilliantly-coloured blossoms, which are naturally of a drooping character, can be seen to advantage. They should be grown in good soil and kept well supplied with water, and if placed in a moderately cool, dry house they will produce a charming display of flowers for months in succession. See our article and illustration in the issue of June 7, page 131.

Pruning the Oleander (C. M.).—The Oleander is naturally of a loose, Willow-like style of growth, so that any attempt to keep it dwarf will result in the production of few, if any, blossoms, and, generally speaking, the more-pruning the fewer flowers. Still, if the plant is not showing flower, it may be cut back to within a couple of feet of the pot at once, or, if there are any blossoms, as soon as they are past. Good, stout shoots are very necessary for flowering, hence, in cutting back, any weak and exhausted shoots may be removed altogether. If you cut your plant back now, you must not be surprised at a poor floral display next year.

Campanula glomerata (Constant Reader).—The plant which you sent for seed flower is *Campanula glomerata*, a hardy border perennial growing about 18 inches high, and producing its violet-purple flowers in clustered heads on the top of the stems, and sometimes also in axillary clusters in the uppermost parts of the stem. The plant may be raised from seeds, though a better way of obtaining a quick return would be by the purchase of half-dozen plants from any of the hardy plant nurseries. The plants may be had for about 6d. each. It is not quite hardy, but grows freely in any ordinary garden soil. The plant may be increased by dividing the roots in early spring. There is a large-flowered kind known as *C. C.* speciosa. This is a rather stronger grower.

Smilax not starting (J. G.).—A very difficult question, as there is no apparent reason why your plants have not started into growth long since.

If you think the roots at the base of the bulbs are in a bad state, and should advise replanting in some new soil. A mixture of equal parts of loam and leaf-mould or peat, with a liberal dash of sand, will form a suitable compost. Plant the bulbs so that the upper part is about 1 inch below the surface of the soil, and avoid overwatering. It is necessary, also, to see that the box is well drained. If you have an ordinary frame, kept fairly close and shaded from direct sunshine, it will be better to pot the box in there than in theinery till the plants are well started into growth.

Plants for cold greenhouse (D. T.).—We can recommend nothing likely to conform to your requirements, for to obtain flowering plants in the depth of winter more heat is absolutely necessary. Bulbs, such as Hyacinths, Tulips, Narcissus, etc., may be obtained in autumn, potted, and placed out-of-doors. Then, early in December, take them into your greenhouse, where they will come on gradually, but they are not likely to flower till February. Little bushes of the hardy *Campanula glomerata* Azalea mollis are sold in large quantities for winter forcing under glass. All they need is to be treated much as the bulbs above mentioned, but, like them, they cannot under such conditions be had in flower till winter is almost, if not quite, past. The winter-flowering plants need only greater care in temperature, but, at the same time, a considerable amount of cultural skill is required to get them on to flowering size.

Bouquet competition (V. B.).—If you had enclosed the leaf of the exhibition schedule on which the bouquet classes are mentioned, we might have been better able to reply to you. However, a shower-bouquet means one made up in the usual way, but the flowers light and set out all crowded. From one side of the face of this bouquet down, some 2 feet in length, sprays of Smilax or Asparagus plumosus, either four or five, and of these drooping sprays of flowers, similar in colour to the chief ones in the bouquet, are wired at a few inches apart. A marriage or wedding bouquet is now invariably of the same style, but composed entirely of white flowers. We know of no spray-bouquet but there are sprays for ladies' wear. These are invariably from 6 inches to 7 inches long, from 2 inches to 3 inches broad, and slightly curved. They should be light, have a base of Ferns and Asparagus, and consist of about two colours of flowers only.

Pampas Grass, moving (Tribble).—The grass is obviously in uncongenial soil, and we advise, if there be not much new growth, to cut the leaves down, say, 15 inches of the earth, and then lift the plant carefully and replant at once in its present position, then it will be well to lift, remove in a couple of hours of the old soil, and replace with good loam, leaf-soil, one-third of manure, and the same quantity of old mortar-rubbish. Old plants are best if divided at times, and this may be necessary in your case, dividing the plant into three or five parts, and replanting the divisions in a circular group, with a little distance apart, yet in such a way that the whole may again form a good single specimen. In case of water following the division and planting, take care that watering is given at the time. Also encourage new growth by frequent watering overhead. Take care that the roots do not suffer from dryness during the time they are out of the soil.

Palm falling (K. Y. B.).—It is impossible to definitely state the reason of the leaves of your Palm falling, affected as it is in the specimen sent, but it appears to be irregular or irregular watering, pot-bound, and there. Again, when plants are very much starved, the leaves are more suffer from a kind of semi-starvation, the leaves are apt to go in this way. If such is the case with yours, it had better be repotted, using a compost of two-thirds good loam to one-third of leaf-mould, with a little sand.

The pot should be large enough to allow of 1 inch to 1 1/2 inches of new soil around the old ball, and, at the same time, it must be effectually drained. When a Palm is much pot-bound, repotting is, however, by no means absolutely necessary, for a little weak manure-water occasionally or some of the concentrated manures that are now so much in vogue and so easy of application, will do all that is necessary. Should the state of the leaves be caused by an unhealthy condition of the roots, the only remedy is to remove as much of the old soil as possible, and repot. In any case and in any stage overpotting Palms should be studiously avoided. As far as one can judge from a small portion of the leaf, the specimen sent is, we should say, *Chamaerops humilis*.

Anemone fulgens, Gentian, Salvia, etc., from seed (G. B. L.).—We cannot say how long it may be before the Anemone seedlings appear, so much depending upon the freshness or otherwise of the seeds. The tubers are infinitely more satisfactory, because these grow at the right time and flower well. Moreover, the roots—i.e., tubers—are so cheap by the hundred or dozen that purchased seeds may prove disappointing. Freshly gathered seeds are best sown at once in shallow drills in a north border, covering one-quarter of an inch deep with fine earth. Such as these make growth the ensuing spring as a rule. The *Salvia* should be sown in slight rows in February or March, and the seedlings will lift quickly. However the ensuing autumn, *Gentian* seed is best sown in pans or boxes of very sandy soil, the rarer kinds taking from one to two years to grow, and in the seedling state progress is very slow. Seeds of the commoner kinds, if plentiful, may be sown as you suggest, making the soil quite sandy. In such a case we would prefer covering the seed with slates or boards to stay evaporation.

Herbaceous border (Slow Coach).—In the space you dispose it would be easy to form a border of the better class of perennials to make a display over a long season. You certainly possess a fair width and a good proportionate length in which to carry out really effective groups. We are not sure we define your meaning when you refer to a border "arranged in progressive order." There is a large border at Hays, in which large numbers of plants may be seen, but there are annuals and other such tender plants in it also; and, again, some groups of statos, the *Iris* and *Ponies*, are quite absent from it. In these two groups we have some of the best flowering plants for June and July, and we take it, unless a border is laid out specially to give effect at certain seasons, that such showy subjects cannot well be spared from it. We would furnish you with a list of plants likely to suit, but we think it best, as the work cannot be done at this time, to let you quite understand your requirements, and particularly as to whether you desire a gay border during any season, or a representative herbaceous border of good and showy plants? Depth and character of soil may also be given, as these are helpful.

FRUIT.

Strawberries failing (A. W. M.).—It is not to be wondered at that your Strawberries have failed. The tests show that the soil is quite exhausted from their being too long in one place. Three years is quite long enough to allow the plants to be grown in one place. You ought to at once set about making a new plantation, following the instructions given to G. Watts, page 27.

Strawberries in pots (P.).—These should stand lightly on a bed of ashes after potting, in some open situation where they can receive as much sunshine as possible, regularly removing all runners and weeds. Two or three good waterings with liquid-manure will, when the pots are bed with roots, be beneficial at intervals of a week or so, as it must not be continued too late in the autumn, especially if the plants be intended for early forcing, or if you wish to have the crowns too much, and delay that abstraction which is essential to the production of a good crop of fruit.

Watering fruit-trees under glass (Pittman).—It is a very difficult thing to arrange further particulars as to soil and formations of borders—i.e., whether the drainage is good or otherwise. You ought to have given our trees a thorough soaking, sufficient to reach all the pots, when the fruit set, and then applied a good mulch of rotten manure to retain the moisture. Water freely, once a fortnight, during the summer when the fruits are green and swelling, thus washing the goodness of the manure to the roots of the trees. A too heavy dose of manure when the fruits are colouring will cause cracking, and spoil the flavour.

Secondary flowers on Plum-trees (Down).—You might as well pick off the secondary flowers on your plum-trees, as they are useless. No doubt, as in often the case, some cause operates unduly to develop bloom-buds in your case, perhaps, the transplanting of the trees in March, when it would have been better to have done so in October or November. We assume that the branches, which in May were cut back to one-half of their length, have broken into growth, and each one has thrown three or four shoots? If so, then the foundation has to be laid for the formation of proper heads later. Those shoots will, perhaps, need some thinning of the inner ones in the winter, if they seem to be too thick, and shortening one-third. After that, a mere thinning of branches or shoots will suffice, as the trees should then soon begin to fruit.

VEGETABLES.

Ear-worms (G. B.).—You do not tell us the nature of the soil bed, 15 feet by 8 feet, which is infested by ear-worms, but we assume that it is inside a house or frame. The preferable course would be to remove the soil outside, spreading it about 9 inches thick, dressing it with half a bushel of fine gas lime, letting it lie on the soil, and watering it in after a couple of weeks' exposure, and repeating it a fortnight later. Some three months of such treatment should destroy all ear-worms in it. If you allow the soil to remain in the bed, and mix with it half a bushel of gas-lime, you cannot well use the bed again for some time. If you have anything growing in the bed, you had better, as a palliative now, water it once a week with a strong soot-water, putting a bushel of fresh soot into a coarse bag, and soaking in 20 gallons of water for a few days. If you cleared out the soil and thoroughly hot-soaked the bricks or boards of the bed, you could repare with sweet, fresh soil at once.

SHORT REPLIES.

Zitella.—See reply in this issue, page 288.—N. H. J.—Very likely your Peaches have split stones. We should like to see a fruit before deciding. If you send us a specimen, we will do what we can to help you.—Allen Edward.—"The Subtropical Garden" can be had from John Murray, Albemarle-street, London, W.—Constant Reader, Ireland.—Strawberries and Roses received a mass of pulp, quite unable to form any opinion as to the cause of failure.—H. Brown.—See reply to E. Terry and others in our issue of July 5, page 218, re Roses with green centres.—Ajax.—See reply to "E. M. M." re Spanish *Iris*es, in our issue of July 19, page 265.—M. G. L.—You cannot do better than get "The English Flower Garden," in which the subject of "Air and shade" is dealt with. The price is 15s. 6d., post free, from this office.—G. R.—You cannot do better than use Peruvian Guano, which mixes freely with the water.—Gardener.—See reply to "K. C. B.," re "blistered Peach-leaves," in our issue of June 28, page 235.—A. D.—1. We have seen neither box nor insects. 2. So long as your plants are growing well there is no need to feed them. We should certainly not feed until you find that the soil is exhausted, which the plants will soon show by the colour of the leaves and the poor growth.—Oakley.—Your best plan will be to call in someone to advise you on the spot. It is difficult to advise you without seeing the garden. You can get the burr from the brickfield far cheaper than you say—in many cases for the price of cartage only.—Co. K.—Get 1 peck of lime, 1 peck of soot, 6 lb. of sulphur, boil together for two hours, and, when cool, use 1/2 pint to 4 gallons of water, preferably soft water, syringing the Rose with same.—Eust Lothian.—Apply to Gilchristson and Page, Hertford.—Mrs. E. M. W. Mayou.—Your Azaleas are a mass of thrips and red-spider. See note as to treatment in our issue of July 5, page 283, and also reply to "A.," page 288.—A. Lecturer, Lambeth, Trinidad, and Poppies are best divided in the autumn. 3. Stand your Rose in the open air to ripen up the wood. See article on Rose Niphetos in present issue, page 278.

Catalogues received.—Jas. Douglas, Great Bookham, Surrey.—List of Carnations, Auriculas, etc., and a List of Choice Dahodites for 1902.—E. H. Kregel and Son, Haarlem, Holland.—List of Dutch Bulbs.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the EDITOR OF GARDENING ILLUSTRATED, 17, Furnival-street, Holborn, London, K.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—Miss Corke.—*Spiraea flagellata* syn. *S. hypericifolia*.—Chas. Blackwell.—We cannot undertake to name florists' flowers.—John O'Donnell.—*Deutzia crenata*.—An *Old Subscriber*.—*Kalmia latifolia*.—Mrs. Newman.—The Throat-wort (*Trachelium inculcense*).—B. Colwell.—*Aechusa italica*.—J. M. W.—Specimens insufficient.—A. Mox.—1. We cannot undertake to name Roses; 2. *Lysimachia nummularis*.—Sandhills.—Form of *Orchis latifolia*, as far as we can make out.—Mrs. Holt.—White *Ramanas* Rose (*Rosa rugosa* alba).—Miss Dutton.—*Phacelia (Rosa)* (*tanacetifolia*, a hardy annual from California).—T. Hunter.—1. *Thiladelphus microphyllus*; 2. *Deutzia crenata*; 3. *Deutzia crenata* flore-pleno; 4. *Spiraea Douglasii*; 5. Please send in flower, looks like a *Viburnum*.—P. M. Wells.—1. *Crinum capense*; 2. *Anemone rivularis*; 3. *Cornus tomentosum*; 4. *Spiraea Bumalda*, variety of *S. japonica*; 5. *Aristolochia Clematis*; 6. *Diplopappus chrysophyllus*.—J. G. G.—1. One of the many hybrid *Pinks*; 2. *Rose Balm* (*Moss-rose didyma*); 3. *Campanula lactiflora*; 4. *Hellianthemum vulgare*.—W. Allen.—1. *Linaris purpurea*; 2. *Entola* (*Phacelia tanacetifolia*); 3 and 4. We cannot name florists' flowers.—Bluzbam.—The White Bean (*Pyrus Aria*).—Frank Piper.—1. *Potentilla*, one of the many hybrid forms; 2. *Festuca glauca*; 3. *Lysimachia vulgaris*; 4. *Verbascum vernale*.—Rockery.—1. *Achillea ptarmica* fl.-pt.; 2. *Campanula rhomboidalis*; 3. *Sedum album*; 1. *Campanula pyramidalis*.—E. K. D.—1. *Coronopus Dogwood*; 2. The Cockspur Thorn (*Craegus crus-galli*), form *et.*—Eugénier H. M.—*Ligustrum japonicum*.—J. W. I.—*Campanula periclyifolia*; 2. Goat's-beard (*Spiraea Aruncus*).—S. Leak.—1. *Lychnis fulgens*.—M. F. S.—1. with yellow flower, *Verbascum phloxoides*; 2. *Rhododendron Wilsoni*, probably. —Fugénier.—*Stachys* (*Stellaria Holsteae*).—Allen Shaw.—Specimen quite shrivelled up.

Patent Greenhouse BOILERS.

The special merits of our Boilers are—

1. Long Burning.
2. Even Temperature.
3. No Trouble.
4. The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition.

Guaranteed Minimum Burning 24 Hours Without Attention.

It goes without saying that the large reserve of fuel in the Feeder makes burning for at least four times longer than is possible with ordinary boilers. Thoroughly satisfactory Boilers can be replaced in a few hours work without moving existing pipes.

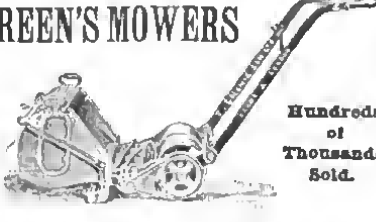

EXTRACTS FROM LETTERS RECEIVED.—

"My gardener says he never had such a stove before, so easy to work, and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove I ever had." "My man handles it." "The last No. 21 had from you always goes 24 hours at a stretch. I never look at it but once a day, and have a good even heat the whole 24 hours."

VEGETABLES.

THE POTATO DISEASE.

I have to wish to pose as an alarmist, but it is certain that we must be prepared to see evidences of the Potato disease of a somewhat extensive nature soon. But a few days since I saw in a Surrey cottage garden, and one that was remarkably neat, in the leafage of some early Potatoes as bad an attack of the disease as I had, in a preliminary way, and so early, seen at any time. It was somewhat reassuring not to see any further evidence of the disease in any other garden or allotment in the locality, but, as was the case in this instance, the spot appears so suddenly and in such a severe form that it may be found in any breadth of Potatoes at any moment. The attack in question had followed almost directly on a heavy thunderstorm, and naturally led to the assumption, as was the case in past years, that the spot is of electrical production. But there can be no doubt that July heat causes the spores of *Phytophthora infestans* to become abundantly active in the air, and only moisture is needed to cause them to be exceedingly fertile. That moisture thunderstorms supply, as the heavy rains which accompany them fall on heated soil, thus creating vapour or mist, which, condensing, settles on the Potato leafage and supplies moisture such as the spores need. Then they penetrate into the leafage, produce mycelium, which eats up or kills the chlorophyll or green colouring matter in the leaves, and destroys the cuticle, so that the leaves and stems also speedily wither up and die. Whilst doing this harm, the fungus produces a white mildew or mould on these spots, which creates other spores or seed by myriads, and thus the disease is extended to all living Potato leafage and stems near by. No wonder that a breadth, green on one day, may be diseased and blackened in a week, so rapid is the fungoid growth.

It is only by the application of the Bordeaux mixture to the breadths of Potatoes that it is possible to combat the fungus. That remedy, whilst so well known, seems to be very little used. It is cheap, and easily made and applied. Were it some expensive patent fungicide, no doubt many would purchase and use it. Gardeners seldom do, for instance, and yet if they or anyone will get a large cask or wooden tub and the ingredients, they may make with 2 lb. of sulphate of copper or bluestone, and 2 lb. of fresh lime, 20 gallons of the mixture, enough to spray a big breadth of Potatoes. One authority asserts that for the sum of 3s. an acre of Potatoes may be well sprayed so far as the materials are concerned, and that a man with a knapsack sprayer may do so much in a day. With a couple of sprayings, one, now and one a fortnight later, the Potatoes may be so far saved as to make a difference of 2 tone per acre in the tuber produce later, or some £3 to £4 value in gain. Generally the disease does not appear until about July 20th, but, as shown, it has appeared earlier this year, and may in thunderstorm

areas have spread widely by the end of the month. In some preceding years we have not seen it until August. The 2 lb. of bluestone should be dissolved in 20 gallons of water placed in the tub. To assist the process, the solid should be occasionally moved. Then dissolve in a gallon of boiling water 2 lb. of fresh lime and 2 lb. of common treacle or molasses, pouring the latter when clear into the tub. The bluestone is helped to be dissolved also if first put into a gallon or two of boiling water, the other quantity being added later. When adding the lime solution stir the liquid well. When settled it should be of a pale green colour. It is best applied in light spray or vapour form. A. D.

SALT IN THE GARDEN.

By very many owners of gardens salt is treated more as a poison to weeds than a fertiliser to the soil. By most persons weedy walks and Asparagus-beds alone are associated with salt, but there are soils and other crops that benefit from a judicious use of salt. Any and all of the Brassica family are sometimes benefited by a light sprinkling in summer. Beetroot, Spinach, Seakale, Onions, Leeks, Celery, and Carrots are benefited by a sprinkling of fine salt on the soil just prior to the sowing or planting. Asparagus absorbs salt, and Seakale does all the better for a small dressing once or twice during the year. Excepting for Seakale and Asparagus, I usually employ salt more as a deterrent to slugs and worms than as a stimulant, though it serves the two-fold purpose. This season, with such frequent rain showers, slugs and large earthworms are very destructive to small seedlings—indeed, much seed has been weated and valuable time lost from this trouble this year, causing both inconvenience and extra cost. Lime and soot are valuable helps in combating slugs, but in showery weather these quickly lose their effect. So, also, would salt, but perhaps not quite so soon as lime. In using this it is most important when applied to anything tender that it be pounded fine. For Asparagus and Seakale, however, it does not so much matter. I find a 4-inch sieve most useful to pass salt through; there are then no lumps to deal with, and there is greater economy because it may be spread so thinly and easily. For anything except the two crops just named only a mere sprinkling is advised, the lighter the dressing the better. It is better to give a little twice or even three times, according to the nature of the soil and the weather. Heavy land is not benefited by salt in showery weather, because it tends to make it still wetter and cold. Light soils certainly derive benefit from it in summer. What is called agricultural salt is that used for land, but I do not find it easy to procure locally. Sundriesmen supply it; but I got ordinary bar salt, and either pound it up with a mallet or rub the lumps on the wire of the sieve, a method I find produces a fineness scarcely possible by the use of the mallet alone. Unless good agricultural salt can be had it is cheaper to have the ordinary bar salt. That which has been used for some other commercial

purpose—in the curing of bacon, for instance—has but little value for the purpose. I should consider this almost dear at a gift; at least, what I have had from bacon curers has not proved sufficiently profitable to satisfy my purpose. Now is a very good time to apply a dressing to Asparagus-beds, both for the purpose of supplying a stimulant to the plants and also as a weed destroyer. It is better applied now than in spring, when the ground is too cold. W. S.

NOTES AND REPLIES.

Summer-sown Carrots.—This is the time to make a sowing of any good Carrot, such as Nantes, Model, or Intermediate, for winter pulling. There should be at disposal ere now vacant plots of ground from which early Peas, Potatoes, or other crops have been taken, and on which Carrot seed may well be sown. In no case is it desirable to have a large bed. One ranging from half a rod to a full rod in area will usually furnish enough Carrots to supply ordinary garden requirements. The soil from which any crop has been taken may well be forked over 6 inches deep and neatly levelled, then have shallow drills drawn 10 inches to 12 inches apart. If the time and soil be just then very dry, much help is given to seed germination if the drills be well soaked with water just before the seed is sown. Carrot seed is now free from hooks, and it does not cling as was formerly the case, hence it is easy to sow thinly, especially as it is not purposed to thin the plants, but to pull the roots in the winter just as they are, using them small and fresh.—A. D.

Late winter greens.—All gardeners will do well to make at the end of July small sowings of the Hardy Green and Rosette Coleworts, Early Gem and Ulm Savoys, St. John's Day Cabbage, and Asparagus, and Chou de Milan Kales. These sowings, if kept watered in dry weather, shaded, and protected from birds, will give good plants to put out early in September rather thickly on to recently vacated ground, and they will give, if small, at least most useful cutting material for the late spring, when it will be all of great value. It too often happens that because all descriptions of winter plants are, in accordance with the customary advice, sown in March, April, or May, there is with most of the plants far too early hearting or heading, and a glut of material is furnished when not required. It is better to make these small late sowings for the sake of getting late plants, as during April and May there is too often great scarcity of green stuff, and then any late crop, be the heads however small, is of the greatest service.—A. D.

Tomato Early Ruby for early crops.—When a good selection of this can be had it is hard to beat for early work. I have grown it for this purpose for years, and can find nothing better. It is free fruiting, and this in the early stages, and even when planted out it does not get coarse, like so many kinds. This year, early in June, I saw a fine crop of this at Montacute House, near Yeovil, in a low span-roofed pit sunk 3 feet in the ground. The borders in which the plants were growing

were from 2 feet to 3 feet wide and shallow. They were 10 inches apart, from seed sown in the second week in February, and good fruit was ready to cut the last half of May. They had commenced to fruit close to the ground. In some instances there were from eight to twelve fruits in a bunch, and I considered it would take from five to seven to a pound. The plants were kept to single cordons, and from the cropping they grew slowly. I have it this season equally free in boxes on a shelf at the back of a lean-to vineery. I have tried many kinds, and think the sorts that have cut, narrow leaves and slightly corrugated fruit are the most free fruiting. I have one now under the name of Lord Roberts of this type, and it is very good.—J. CROOK.

Scarcity of Cabbages.—It may almost seem incredible to speak of the scarcity of Cabbage, but that such exists has been plainly shown recently in the market and garden. The reason for this is easily explained. During June there were almost continuous rains, and these coming on full-grown Cabbages caused wholesale decay and bursting. The beds then, too, were in such a state that many already uncut would be full-hearted. The outcome of this is that a great quantity must be cut at a sacrifice, which obviously means scarcity afterwards, or until there are successive beds maturing, or a forward second growth on those cut early in the season. This scarcity is felt, too, the more keenly because it happened while Pess and Cauliflowers were neither cheap nor plentiful. With the opening season of the Pea, Cauliflower, Broad Bean, and other summer vegetables, there is not usually so keen an enquiry for Cabbages as this year, and the instance affords another truism of the fickleness of the English climate and its influence on vegetation.—W. S.

Tomatoes in Scotland.—As far as the season has gone (from a private gardener's point of view), Tomatoes have set pretty freely on the whole, taking into consideration the almost sunless weather we experienced in May and June. This season's trials here include Holmes' Supreme, Dobbie's Champion, Conference Improved, Klondyke, and Eclipse. Contrary to my expectations, the first-named has been very difficult to set, and the fruits, although of good shape, have not exceeded eight or nine on a truss. The second on the list I find promises to bear a fair crop, the fruit being of a smooth, round shape and of good flavour. Conference is also a shy setter, the fruits smaller than in the last-named, but of a delicious flavour. Klondyke is showing well, and promises a heavy crop, many of the trusses bearing as many as twenty-one fruits, all of good size, of a flattish shape and fine flavour. This variety would make a good market gardener's sort. Eclipse is a good, old, well-tried variety which I never fail to grow. It is good for any purpose, is a very free setter, and an exceptionally heavy cropper. The above are all receiving the same treatment, and all are quite free from disease. It would be interesting to have notes from other readers.—D. G. McIVER, *Bridge of Weir, N.B.*

Early Turnips.—Where facilities do not exist for growing early Turnips under glass it is important that the very earliest kind should be grown. In seed lists many kinds are named, and certainly there is a great advance of late years in kinds that bulb early and are suitable for frames or early borders, compared with the large topped white kinds. I am aware these early kinds have not the flavour, but this is not of so much importance as their earliness. During the last few years I have tried many kinds, and from several seed firms. Some five or six years ago I had a fine stock of Early White Milan. Every year since I have ordered the same kind, but never has it been true like the first stock. This year I ordered this again from a firm in New York. This was sown side by side with seed from another firm in England. That from New York was the very best stock I have ever seen. Out of three rows, each 20 yards long, there was not a rogue or coarse hnb, and good hulhs were pulled under eight weeks from a sowing which was made in the last week in March. Early Purple Topped Munich, sown at the same time, was ten days later. One firm sent Purple Strap-leaved for White Milan.—J. CROOK.

PLANTS AND FLOWERS.

ROOM AND WINDOW.

TUBEROUS BEGONIAS IN WINDOWS.

THE increasing popularity of these proves their great value as garden plants; but, much as they are cultivated, they deserve to be still more known, for not only are they of great service for the embellishment of conservatories and greenhouses, but they are also capital for bedding and among the best things that can be had for windows in dwelling-houses, where they succeed well and flower in the greatest profusion. Plants in windows generally get killed by getting too much water; but with these Begonias there is no fear of that, as they are moisture-loving subjects, and, unless they actually stand in saucers of water, they cannot scarcely be kept too wet, especially when they become pot-bound and are rooting freely—a time when there is a great demand on the roots. Besides their adaptability for window culture they are not subject to insects like other plants,—a circumstance greatly in their favour—and once they begin to flower they keep on and

cut in to two eyes, so that strong breaks are ensured and a compact habit preserved. As soon as the young shoots form, shake out and repot in a good loamy compost, with some well-decomposed manure or a pinch of some concentrated stimulant to each potful. Leaf-mould, at the rate of one-sixth of the whole bulk of soil, induces root formation and promotes free growth. From the middle of June onwards the plants may go into the open air for an hour or two every day.—J. C. B.

Shading flowers.—Those who grow flowers for exhibition find that shading the bloom is an absolute necessity at times, and, whether it be Roses, Carnations, Dahlias, or whatever subject one wishes to have in perfection by a given date, means to screen them from hot sun have to be brought into requisition. A very cheap and handy contrivance may be made with pieces of tin or zinc about 10 inches square, screwed to a stake, and bent over at the edges as desired, being placed over the bloom at any height needed. A rather more expensive arrangement, and one often adopted, is to procure a zinc disc, on the side of which a slot is fixed, through which an iron rod is placed, being fastened with a peg at the required angle, and these, if painted, last for

The Begonia as a window plant.

last in beauty the whole season through. As they are apt to draw if put in windows too early, it is best to start them and get them forward in cold frames, where they should be placed on a cool, moist bottom, and have a little shade during the sunniest part of the day. Thus treated, their progress will be rapid, and they will keep sturdy and strong. If wanted large, the points of the shoots may be nipped out, which will cause them to break back and become well furnished.

NOTES AND REPLIES.

Double Fuchsias in windows.—One does not often see well-bloomed specimens of double Fuchsias in windows. In a general way they are not so robust as the single-flowered kinds, and not getting so much light and air as when cultivated in a greenhouse, the growth made is too weakly to admit of the production of good blooms. The unfavourable conditions may in a great measure be counteracted by putting the plants in the open air on all favourable occasions. By exposing them to the direct influence of sun and air, the young wood will be strengthened, so that the buds will be able to expand instead of dropping before opening, as is frequently the case. In pruning them back in March it is advisable to

years. Not only is shading flowers in this way indispensable to the exhibitor, but growers of blossoms for table who desire them to keep for the longest period with colours well retained will find the little trouble and expense serve them well. It is next to impossible in hot, dry weather to obtain Roses well formed and highly finished as to colour. Take as examples such varieties as La France, Mrs. W. J. Grant, and William Allen Richardson; one knows only too well that if they are exposed for a few hours to hot sunshine the delicate colours fade, and they lose much of their beauty. Particularly is this seen in the flowers of W. A. Richardson, which quickly bleach; but when shaded and gradually developed few Roses are more popular. A point of equal importance is that flowers screened in some way from sunshine last much longer when cut. Some people object to their borders having "shades" about them; but in hot weather, as we have recently been experiencing, there is no alternative but to revert to some such practice if flowers are to be had in good condition. The mere fact that blooms thus grown last much longer when gathered should not be lost sight of, and for this reason it is worth one's while to go to some little trouble and prevent the unduly expanding of buds that are promising.—L. H. WAST.

OUTDOOR PLANTS.

THE PEACH LEAVED BELLEFLOWER
(CAMPANULA PERSICIFOLIA).

THE various forms of the Peach-leaved Bellflower are among the finest of open-air flowers. They are also well adapted for growing in pots; indeed, few things are finer than good specimens in 8-inch pots of grandiflora and the double white variety. It is a pity that they are a little capricious as regards soil. In many places they die out in the course of a season or two, the collapse usually happening after they have bloomed freely and in very dry weather. For some years I failed to keep these Bellflowers in good health in my light soil; but, finding them so valuable for cut bloom, I made a piece of ground for them by adding some retentive material and decomposed manure. In this I find they do much better, and last season I had a fine show of bloom, and I see that the plants are throwing up well for bloom again. As the single varieties form seeds very freely, the flower-spikes should be cut down as soon as the last flowers fade, and it does them an immense amount of good if they then get a good soaking of weak liquid-manure, or, should the weather be showery, a top-dressing of rotten manure or of some stimulant. In soils naturally favourable this attention is not so necessary; but in the case of light, porous land, and when the flowering time is followed by great heat and drought, the vitality of the plants is permanently lowered unless they get some attention. The typical single-flowered forms are now in a great measure superseded by varieties having larger blooms. Both alba grandiflora and cerulea grandiflora have flowers nearly twice the size of those of original forms, and they are very free blooming. Two very fine forms are maxima duplex and alba maxima duplex, with semi-double flowers; they are vigorous growers, and in groups of a dozen good specimens create a fine effect. Another fine form recently distributed by a Dutch firm is Morheimi; the flowers are pure white, and seem to come midway in form between maxima duplex and alba plena. This should make a fine pot plant.

J. CORNHILL.

STOCKS FOR SPRING FLOWERING.

BROMPTON STOCKS.—A good strain of these comes in useful in early spring, and enlivens our borders just when flowers are none too plentiful. Sow the seed during July, placing the pan or box in a cold frame, and shading until the seed comes through, when place outside, pricking off into other boxes 2 inches to 2 1/2 inches asunder, or 4 inches to 6 inches apart outdoors on a shady border as soon as fit to handle, care being taken in transplanting that the stems do not get bruised. Towards the end of October lift carefully with a trowel and plant where they are to flower, allowing about 12 inches between each plant if massed, but planted three in a group in the herbaceous border they show to advantage. White and scarlet are the colours usually met with.

EAST LOTHIAN STOCKS.—These, again, are most useful, whether under glass or in the open border, but specially in pots during early spring, when, if placed in the greenhouse, they not only add brightness to the house, but their delicious fragrance pervades the whole structure. The same remarks apply as to sowing, pricking off, etc., as given above, but I prefer potting them up in a comparatively small state, as they do not appear to feel transplanting so much when small as when they have made much top-root, which should be preferred as well as possible. I find 6-inch pots a serviceable size to flower them in, potting firmly, using loam, leaf soil, and sand, with a little finely broken brickbats with the soil, placing them into these pots about the middle of September, and in a month from then changing the pots to the rims in a cold pit or frame, where all the light and sun during winter may reach them. In this position little or no water will be required from the end of October to the end of January if an inch or so of Cocoa-nut-fibre be placed over the pot to prevent evaporation and act as a mulch against frost. In the warmer counties the plants can be set out in beds and borders early in

October, and provided the winter is not particularly severe, the plants are a mass of flower towards the end of May, and continue well into the summer, when if a further sowing be made early in March a display can be had quite late in the autumn. My experience with East Lothian Stocks is that a greater percentage of doubles can be got than from any other species of Stock, and it is wise to get the seed from a good firm. These Stocks are most useful for cutting. Those in pots may be stood in the house when nicely in bloom, their delicious scent being much appreciated by most people. When feeding the plants in pots early in spring great care is necessary that the manure is not used too strong. When planted outdoors let the ground be in good heart, working in plenty of well-rotted dung when trenching.

J. M. B.

FLAG IRISES.

It is rather a sweeping assertion to say that we owe more to the Iris family for the embellish-

ment of our gardens than to any other, and I can imagine the incredulous contempt with which the statement will be received by the worshippers of the rival queens of the garden, the Rose and the Lily. No one but will admit that when these are at the zenith of their display they eclipse all lesser lights; but the Rose does not expand its petals earlier than May in most genial seasons, except in the south-west, where the great single white Rosa lavigata may sometimes be seen bearing its first flowers in April, and the first of the Lilies is rarely in flower before the opening days of June, while September sees the rear-guard of the Tiger Lilies glow in the autumn sunlight. Now that Tee and China Roses are so largely grown, September, October, and even the early part of November, if the weather be mild, are not Roseless months; but after that for nearly half the year the open garden knows not the queen of flowers, but while she bides her face the Iris has been bravely blossoming. As early as the closing days of October the

Algerian Irises (*I. stylosa*), lavender and white, commence to expand their delicate, scented blooms, and continue to flower, as long as the land is not frost-bound, until April. From November to Christmas time and early January the Scorpion Iris (*I. alata*) opens its lovely flowers, followed by *I. persica*, *I. histrio*, *I. histrioides*, *I. reticulata*, *I. Heldreichii*, and many others. Then come the hybrids of *I. pumila*, with their dwarf flag leaves, and shortly after *I. chamaeiris*, *I. pumila*, and *I. olihiensis*. Next we have the Spanish Irises, yellow, white, and blue, the Flag Irises, and in July the handsome English Irises, followed by the stately golden *I. aurea* and *I. Monnierii*, and the white and yellow *I. orientalis* or *ochroleuca*, all three of which often attain a height of 5 feet and flower until August, so that there is only one month in the twelve when Irises may not be gathered from the open border. The Onocycclus, or Cushion Irises, such as *I. Sasiana*, *I. Gatesii*, *I. Loreti*, and others, bear immense dotted flowers in the summer, but the

A group of German Irises. From a photograph sent by Mr. Jas. E. Tyler, Halestead, Essex.

difficulties of their successful culture are too great for them to become popular with the ordinary amateur. This, however, is not the case with the subject of this note, the Flag or German Iris, whose requirements are of the simplest description. It may be seen flowering freely on steep railway embankments, the soil of which is baked during the summer to a brick-like hardness, and bearing its great purple flowers in sheaves beneath an old standard Apple-tree in a cottage garden. The type and its white form are most commonly met with, but there are numberless named varieties of great merit that are of equally easy culture. Of these a good selection is Apollo, yellow, with crimson falls; atro-purpurea, purple-black; Bridemaid, white, suffused with blue; Cordelia, lavender and purple; florentina, white, turning pearl-grey, fragrant; flavescens, pale sulphur; Mme. Chereau, white, heavily margined with lavender-blue; Queen of the May, rosy-lilac; pallida, pale lavender; pallida, dalmatica, lavender-blue; both of the

URBANA-CHAMPAIGN

two last-mentioned are sweetly scented, and in good soil attain a height of from 3 feet to 4 feet, and have handsome, broad, grey-green foliage; Princess of Wales, the best white; Victorine, one of the most lovely of the entire race, white, with deep violet markings on the falls. S. W. F.

SAPONARIA (SOAPWORT).

PERENNIAL herbs and alpine plants or annuals belonging to the Pink family.

S. BOISSIERI is a dwarf and showy alpine of quick and free growth, somewhat tufted in character, and spreading out into good-sized plants. It bears freely bright pink flowers.

S. CAESPITOSA (syn. S. elegans) is a neat little alpine perennial from the higher regions of the Central and Eastern Pyrenees, flowering in August, but in the lowlands its rose-coloured blossoms appear towards the end of June. It forms rosettes of thick, glabrous leaves; the flowers, in a thick cluster, are on short, stout stems. This graceful little plant is valuable for the rock-garden. A sandy soil suits it best, and it endures our winters.

S. CALABRICA (syn. S. multiflora) is a pretty prostrate hardy annual, 6 inches to 9 inches high, much used for edgings, its slender stems covered with small pink blossoms all the summer. There is a white variety. Seeds may be sown in the open border in April, or earlier in heat if bloom is required early in the season. The plant thrives best in rich sandy loam.

S. LUTEA, from the Savoy and Piedmont Mountains, has yellow flowers and a woolly calyx. The leaves are narrow and not unlike those of the alpine Catchfly (*Silene alpestris*).

S. OCYMOIDES. — A beautiful trailing rock-plant, with prostrate stems and an abundance of rosy flowers so densely produced as to completely cover the cushions of leaves and branches. It is easily raised from seed or from cuttings, thrives in almost any soil, and is one of the most valuable plants we have for clothing the most arid parts of rockwork, particularly in positions where a drooping plant is desired, the shoots falling profusely over the face of the rocks, and becoming masses of rosy bloom in early summer. It is also excellent for planting on ruins and old walls, on which the seed should be sown in mossy chinks in spots where a little soil has collected. It is also a valuable border plant, forming roundish, spreading cushions, and deserves being naturalised in bare and rocky places. A native of Southern and Central Europe. Although it grows freely in poor soil when it is planted with the view of allowing it to fall freely over the face of the rock, it will do much better by giving it a deep, loamy soil. We once saw a mass of this 5 feet long and 3½ feet in breadth.

S. OFFICINALIS (SOAPWORT). This is a hardy some native plant about 2 feet high, with large

blossoms, usually rose-pink. The double variety is the best. It is a rambling plant, and soon spreads rapidly; therefore, it should not be planted in select borders, but is pretty for rough places in the pleasure-ground and wild garden, as it grows in any soil.

LAWNS.

GRASS LAWNS and smoothly-mown pleasure grounds were, perhaps, never fresher and more beautiful than they are to-day. The cool spring and the recent showers may probably account for this, having so far prevented the sun-scorching so often experienced on dry soils when drought prevails. The same moist conditions which help the lawn Grasses, however, likewise favour the Daisies,

owing to weeds and coarse Grasses having got ahead. Constant rolling, at least once a fortnight during winter, is essential if any thing like a fine and even surface is to be secured.

Old lawns often become weedy partly through starvation, or partly owing to the use of dirty soil or of superphosphate or potash manures for top dressings, which encourage the growth of weeds and Clover almost as much as they do that of the lawn Grasses. It is extremely difficult to obtain either fine earth or well-rotted stable-manure that does not contain seeds of Dandelion, Plantain, and Dock in abundance, so that in top-dressing lawns one is often stocking them with weeds as well as enriching them with manure. Then, again, if burnt earth, wood-ashes, and the like, or potash manures in any form are employed, the result is a growth of Clover.

Newly-made lawns are frequently prepared in a hurry, either on old weedy sites or are levelled before sowing with earth full of weeds and coarse Grass seeds, and then sown immediately with fine lawn Grasses, the consequence being that Grass seeds and weeds come up together, and the seedsmen are frequently and wrongly blamed. There are only two ways of getting weedy lawns clean, the one being a vigorous course of hand-weeding, and the other the persistent use of the most suitable of the so-called artificial manures. Any attempt to weed a Grass plot or lawn by man or boy wandering all over its area with a fork or spud is worse than useless; the only thing for it is to divide it into narrow strips with pegs and twine, or with a lawn-tennis marker, and thus get the whole area efficiently and systematically cleared. The best tool for extracting weeds from Grass is a small two or three-tined fork, by which the whole root may be loosened so as to be withdrawn with the fingers, the surface being pressed down again with the foot afterwards. Spuds and weeding-knives are well nigh useless, and only lead to the work being half done. After weeding, top-dress with clean earth, sow the whole area with good lawn Grasses, and roll well, and if this operation can be done just before rain so much the better.

Some of the finest lawns in England are those at the Oxford and Cambridge colleges, and are the result of years of constant care and attention. One sunny April day we saw the lawn at St. John's, Oxford, covered with brownish cloud-like patches, and asked the gardener why it was? "Oh!" he replied, "we dressed it with sulphate of ammonia last week, and it has been pretty dry since, so the Grass is browning a little; but all that will vanish after we get a shower." A week afterwards the same lawn was as fresh and as green as a billiard table, and the object lesson was not forgotten. This sulphate, while encouraging the Grass, acts very injuriously on the broad-leaved weeds by scorching them, and by regular applications they are done away with altogether, the Grass being meanwhile improved in growth and verdure. In a recent *Journal* of the Royal Horticultural Society of London we find a striking corroboration of the above fact, while at the same time deprecating the use of potash and superphosphate manures for Grass lawns and greens:

"A mixture that has been used with splendid results on some well-known golf links in the neighbourhood of London is made of equal proportions of nitrate of soda and sulphate of ammonia, and applied at the rate of 1 lb. to the rod. This is given several times during the summer months, and if the weather is dry it is thoroughly watered in. More than a pound to the rod is never applied at a time, as it is found that it is better to use only that quantity, and repeat it, than to apply a stronger dressing. Before the application of the nitrate of soda and sulphate of ammonia the greens were literally covered with Clover, but since employing it not only Clover, but all the plants with objectionable broad foliage have disappeared, the reason being that the manure kills the fat leaves and kills them; and by frequently repeating the application any new growths are from time to time destroyed, and this continual weakening of the plants eventually destroys them altogether."

By a persistent and judicious combination of the above hand-weeding and manuring processes, even the weediest and worst of the lawns may be improved, and the hint as to the weed-killing properties of a combination of nitrate of soda and sulphate of ammonia is well worth the attention of all who are interested in the perfect keeping of golf links, bowling greens, and velvety lawns around the house in either town or country. The Field.

The Tufted Soapwort (*Saponaria caespitosa*).

Plantains, and other weeds. Weedy lawns in many, if not in most, cases are the result of poor soil and neglect in keeping. Few people realise how rapidly Daisies ripen their seeds after flowering, or that Daisy seeds are ripe enough to grow when scattered by the lawnmower, even although to the eye they appear quite green. Both Daisies and Plantains, again, are dwarfed in habit by constant mowing, and often flower and ripen seed in the Grass below the cutting level of the machine. In order to secure and keep up perfect lawns, they must have ample attention all the year round. Most lawns and Grass plots are neglected all through the late autumn and winter, say from October until March, when a rush is made to get the ground in order, and very often much disappointment follows.

NOTES AND REPLIES.

Star of Bethlehem as a vegetable.—With reference to a query in your paper, I find that *Ornithogalum pyrenaicum* is eaten in the neighbourhood of Bath under the name of French Asparagus.—J. E. KESSELL.

Tufted Pansies—propagating for autumn planting (W. S.)—If you would have an early display next spring you should begin at once. First determine the varieties in your collection you wish to perpetuate, and then cut back the plants to within an inch or two of their crown. At the same time loosen the soil round about the plants, and mulch them with some nice light gritty compost. This material should be worked into the growths at the crown of the plants, and each one then treated to a copious watering. Under these conditions, and with genial weather, new growths should quickly develop, and, if these fresh shoots are encouraged to grow freely, in a week or two they may be detached and then inserted in a bed of prepared soil. Should you require only a limited number of plants you should cut out the coarse and elongated growths and work in some light gritty soil among the younger shoots retained. It may be possible, in a little while to detach some of the smaller shoots, with roots adhering, and such useful pieces of growth invariably make ideal plants when the planting out time arrives in early October. This process may be continued until a sufficient quantity of stock has been secured. Make up your cutting-bed outdoors, choosing a cool and protected situation. Let the soil be raised a few inches above the garden level, as this is a great advantage in wet weather.—C. A. H.

Snapdragons.—Whether Snapdragons are treated as annuals, biennial, or grown on from year to year, as is often the case, a good display of bloom is assured. A bed of seedlings sown in heat in March is now in full bloom, as is also a group of old plants I have had for several years, and which stood the severity of last winter much better than young plants from a sowing the preceding July. Many people have a high opinion of dwarf plants of all kinds, hence it is that the tall-growing Snapdragons are not seen in gardens so frequently as years ago. In some borders, may be, small growing plants are desirable; but in most places, I imagine, there is room for a few of the tall, branching sorts, which are so effective. Snapdragons will grow in almost any soil, but prefer gritty, sandy compost, and often do well where the soil is not always the most abundant. In old limestone walls and rocks, in the niches of which Wallflowers frequently grow, I have seen Snapdragons blooming freely, so that it is not the quantity of soil that is absolutely necessary. Where accommodation does not exist for raising them in heat in spring, now is a favourable time for sowing seed out of doors, and if wintered in a bed under a fence, most of them will bloom early next summer.—WOOD-BASTWICK.

Montbretias.—In a garden on the outskirts of a town, in a part that had been somewhat neglected, there are to be seen now several groups of Montbretias. The soil in which the bulbs were planted last autumn was almost worn out, but, after digging in some leaf-mould, planting was done. Beyond a mulching of manure in the winter they have received scarcely any attention, and just at the moment they promise well for bloom. I do not think it is generally known

how simple their culture is, and what bloom Montbretias give in a single season, otherwise more would grow them. When once planted, too, they need not be disturbed—in fact, there is no necessity to touch them for several years.—LEAUFURST.

Phloxes in autumn.—A suggestion made in a recent number of GARDENING that cuttings of Phlox should be struck for autumn use under glass reminds me of a way of prolonging the season of this useful and effective garden plant. For many seasons I have taken cuttings in the spring from the outside shoots of an established clump. This has mainly been done with the idea of increasing stock, but the practical result has been a late display of flowers. Selecting short, sturdy growths about 3 inches long, with a portion of underground stem, the cuttings are inserted about April—in fact, any time before the shoots get too long or drawn. They are more certain if struck under a handlight or in a cold frame; but I have frequently put them straight into the open. Either way, hardy treatment is all

Saponaria ocymoides. From a photograph sent by Miss Willmott. (See page 294)

they require. Moved where they are to flower, as soon as they have made roots—in perhaps six weeks' time from insertion, or any time up to the middle of June—they will flower just as the old plants begin to fail. They give a very fine head of bloom on a single stem. As each stem on an old plant is by no means able to do this, there is a clear gain by the proceeding, and the trouble is very slight. These young plants make a finer display the following season than the older clumps. I have no doubt they could be potted up for conservatory use, just as well as later hotbed-struck plants. The hardy treatment is simpler, possibly a week or so longer—that is all.—R. B.

Wild gardens.—“Castlemains” account in GARDENING ILLUSTRATED of her wild garden is very attractive. She seems to have planted it with good taste. The one thing to avoid in such a garden is vulgarising it, as I have seen a mountain glen vulgarised by the introduction of essentially “garden flowers.” To her list one might add for spring Solomon’s Seal (*Polygonatum multiflorum*), a native of Britain, or, at all events, a natural-

ised plant. Such would also include *Hypericum calycinum*, *Saponaria officinalis*, *Linosyris vulgaris* (known also as *Chrysocoma Linosyris*), *Lyssimachia nummularia*, *Geranium sanguineum*, *G. s. album*, *Hieracium aurantiacum* is a native of Scotland. Ferns of any hardy kind can never come amiss. The Periwinkles (*Viola major* and the white variety) would be very appropriate. But one false note in the shape of a “garden” flower would spoil the whole effect.—S. M.

Rudbeckias.—The Rudbeckias are showy in the borders, and come to perfection when many summer flowers are failing. *R. Newmanni* is popular with many, but some, like myself, find it not the best variety where one has to contend with a dry soil, as it needs much watering. *R. maxima* is a tall-growing sort, just what is often needed on the border of a shrubbery. *R. californica*, in point of flower, is larger than both of the aforementioned, and is at present showing colour.—TOWNSMAN.

Gladiolus The Bride.—Whilst there are many enthusiastic growers of the Brechleyensis and gandavensis forms of the Gladiolus, it is a matter for surprise how comparatively few people plant the early sort, The Bride. Admirers of cut flowers and those who grow with this intent ought to become acquainted with the one under notice. The corms are cheap, and can therefore be planted liberally; they will grow in any light soil and bloom most profusely, points that those who make a speciality of flowers for cutting should watch. I have noticed more in the markets this season than in almost any year; but from gardens, where one would expect to see them, they are missing. Growers of lilies should try them, and note how effective they are when placed in vases together.—DERAY.

Annuals.—So soon as annuals that have been sown either broadcast on beds to assist in the flower garden display or on prepared borders for cutting can be handled, they should be thinned out to the respective distances likely to be required to allow for the development of individual plants. It is a great mistake to let them remain crowded thickly together; the size and quality of the flowers are thereby seriously affected and the duration of bloom also considerably shortened. Where slugs are troublesome, it will be found advisable to mix up a goodly heap of fine wood-ashes, adding thereto a fair proportion of soot, and dusting the beds all over with the same. Somewhat choicer annuals that were sown in frames on a slight hotbed will now be nice plants, and may be transferred to permanent quarters at any time. The spring-sown batch of Stocks will be found very useful, especially those varieties of branching habit that are in request for the flower basket. *Cosmos bipinnatus* in different colours is an annual of good habit, growing and flowering freely on rather poor soil, and having beautifully cut foliage as well as light, graceful flowers. Almost identical in height, but of a different shade of colour, is the miniature Sunflower, an annual that makes a very effective group, holds its foliage well, and continues in flower until late in autumn. If bedding plants are rather scarce, one or two large beds may be filled with *Chrysanthemum tricolor* in variety. Very rich colours are obtainable in these *Chrysanthemums*, and, like the Sunflower, they bloom well until the end of the season. Dwarf annuals, such as *Petunias*, *Verbenas*, *Phlox Drummondii*, etc., that were sown early, will, if they were pricked off into boxes or frames, now be nice plants, and they may be planted out at once, as they will bear more cold than *Pelargoniums*, *Fuchsias*, and the like. The remarks made above as to the depredations of slugs on outdoor-sown annuals will also be found applicable to those transferred from boxes or frames. *Zinnias* are the first to suffer, and if they are planted near a harbour for slugs they must be carefully watched until they are well on the move, and remedial measures employed at the first sign of attack.

As many of the most interesting notes and articles in “GARDENING” from the very beginning have come from its readers, we offer each week a copy of the latest edition of either “STOVE AND GREENHOUSE PLANTS,” or “THE ENGLISH FLOWER GARDEN,” to the reader of the most useful or interesting letter or short article published in the current week’s issue, which will be marked thus “*.”

CHRYSANTHEMUMS.

MANURES FOR CHRYSANTHEMUMS.

(REPLY TO "G. F. H.")

CHRYSANTHEMUMS need a change of food, therefore those who are in a position to apply stimulants in variety stand a better chance of success.

SOOT is an indispensable agent to the growth of Chrysanthemums, giving a dark colour and robustness to the foliage. It is most easily applied in a liquid state. The best way to prepare it is as follows: Place at the rate of one bushel in a bag to 100 gallons of water. The bag should be sufficiently fine in the mesh, so that the soot does not wash out into the water. Of all manures most easily obtained, especially by growers residing in the country,

ANIMAL MANURES are depended upon most largely. Local circumstances must be considered in obtaining these as well as other stimulants. Various kinds of liquid-manures, such as the drainings from the cow-houses and stables, are excellent. Perhaps the former is the better kind to use, as it is cooler. In some instances the liquid from the places named cannot be collected in tanks direct. A very good substitute then may be had from a heap of mixed manure. The best plan is to throw clean water over the heap, and allow the water to soak through the manure and drain into a pit at the side of the heap. Sheep-manure, where it can be had direct from the fields, makes a capital stimulant applied in a liquid form, as also do the droppings from deer or cow-manure made in the same way. Fowl's-manure may be treated in the same manner, and is most efficacious as a stimulant. Manure of the kinds named should be used in the same manner as that described for soot, as the qualities beneficial to the plants are in this manner extracted without the inconvenience of solids.

GUANO finds favour with some growers, and is, when of good quality, very stimulating. A 4-inch potful to 36 gallons of water, kept thoroughly stirred when being used, is a safe quantity.

NITRATE OF SODA, used judiciously to strong-growing varieties when the pots are full of healthy roots, has a quick effect upon the foliage and growth of the plants. Should the plants not appear to be making free growth, nitrate of soda quickly excites the plants and prepares them for other food. Half a teaspoonful powdered finely and watered in once or even twice in a season is sufficient for a plant growing in a 10-inch pot. Should the season promise to be a wet one nitrate of soda must not be used, as there would be a greater difficulty in maturing the growth. Plants moderately furnished with roots, owing to their being weak-growing varieties, or through ill health, should not have any nitrate, otherwise the leaves are certain to be burnt around the edges, thus causing a serious check to growth by a partial, if not a total, loss of many fine roots.

SULPHATE OF AMMONIA in careful hands is an excellent manure, perhaps unequalled as a stimulant, but it must be used carefully. It imparts colour to the leaves of the plant and richness to the blooms, which is not excelled by any other manure. The cultivator should be guided by the state of the weather at the time of application, and also by the state of the roots of the plants. Indeed, this latter is the all-important point to consider. Sulphate of ammonia should not be given to the plants until they are well furnished with roots. Used in a liquid form is the correct way to apply it. Many people are afraid to use it as a stimulant because they think it makes the blooms damp, which it assuredly does, but only when used injudiciously; for instance, too strong doses often kill the roots, not only on the surface, but half-way down the soil in the pots. Especially is this the case when the sulphate is laid on the surface in a dry state and watered in. If plants are not thoroughly well supplied with roots, sulphate of ammonia should not be given them at all, as it will do more harm than good in that manner. The best way to apply sulphate of ammonia is by dissolving a quarter of an ounce in one gallon of water—weak liquid-manure from the farmyard tank is better—commencing as soon as the flower-buds are swelling freely, increasing the strength gradually until half an

ounce is reached to each gallon of water, to be given once a week.

HOW TO FEED THE PLANTS is the next consideration we have to make. Avoid excessive use of any kind. Much better it is to give liquid-manure weak and often. Commence with soot-water, giving it to the plants every time they need water for nearly a week, then withhold it for a time, when it is again used, this time with liquid-manure from the farmyard tanks, or from that made from sheep's-manure. After the buds are formed and swelling freely, stimulants should be given regularly, varying them constantly, as a change of food is desirable. Whatever sort is used it should not be given more than three or four days at a time. During a spell of wet weather it is not possible to use liquid made from animal manures. A little of any of the artificial manures should be sprinkled on the surface of the soil. By this means the plants receive nourishment; whereas, if liquid-manures were entirely depended upon, the plants would not be in a state to receive intervening waterings. In the case of weak-growing kinds stimulants should be given to them in a slightly weaker state than to stronger kinds.

OVERFEEDING brings on premature bud-formation or malformation of the petals, caused by forcing the large outer petals too quickly and not allowing the centre of the flower-bud to fill up by degrees as it should do. When the soil in the pots is approaching dryness is the proper time to apply the stimulants. When the flower-buds are forming in the points of the shoots a check temporarily to the growth takes place. At this time feeding the plants should cease for several days, as undue excitement to the plants is not desirable at that stage, but as soon as it can be determined that the buds are swelling again stimulants may be given. There is also a difference of opinion amongst cultivators as to the proper time when feeding the plants should cease and dependence placed solely on clear water for the finishing of the blooms. Some say that directly the colour of the petals can be seen is the correct time to cease feeding, as stimulants take away the colour of the flowers. Continue to feed the plants until the blooms are three parts expanded, then cease to use stimulants, as it will be found that plants in that stage do not require water nearly so often as those which are in a more backward condition. From the time that the blooms are three parts developed the plants will have sufficient energy bottled up to unfold the blooms to their utmost capacity without artificial aid.

NOTES AND REPLIES.

Chrysanthemums—late stopping of decorative plants (Enquirer).—It has been the practice for years to stop the plants, with the object of making bushy specimens. Operations are first begun in the spring—in fact, from the earliest days of March. Commencing thus early, it is quite an easy matter to lay the foundation of a really good bushy plant. Too often growers commence much later than is desirable, and they expect to achieve results quite equal to, if not better, than their rivals who commenced in the earliest days of spring. The earlier one begins the larger will the plants be. You must also bear in mind that this stopping must terminate within a given period; that is to say, if you desire the plants to bloom during late October and November. For most plants intended to blossom during the period just referred to the last stopping should be completed before the end of June. From this time the plants should be grown on to the terminal buds, these opening kindly and developing blooms of good form by the earliest days of November. Should you, on the other hand, desire a December or Christmas display of Chrysanthemums, you may stop your plants for the last time not later than the present period. Give each plant plenty of room on the standing ground, and see that each one is also carefully staked and the growths neatly tied out. See, too, that the plants do not suffer from want of water.—E. G.

Potting Chrysanthemums late.—You have, in GARDENING ILLUSTRATED, dealt so fully with the cultivation of Chrysanthemums that it seems almost unnecessary to trouble you with any further enquiries, but a diffi-

culty has occurred to me, as may have done to others this very exceptional season, and you would much oblige me by giving me your opinion. I bought my plants in the early part of April, stopped and then shifted them, but they made such slow progress that at the end of June I could not venture to put them into very large pots, and contented myself with 6-inch, 7-inch, and 8-inch pots. Since then, with warmer weather, they are making such good progress that I am in doubt whether it would not be advisable to shift them once again. Shall I do this, or be content with feeding them with manure of different kinds?—AN OLD SUBSCRIBER.

(You would have done better had you allowed a longer time to elapse between the date of stopping them and the potting up into larger pots. In future, we would advise you to allow an interval of at least ten days to elapse between the date of stopping the plants and their subsequent potting. By the expiration of this period the young shoots should be seen, and, when once they have passed this stage, then future progress is generally assured. If you will always bear in mind never to stop the plants and repot at the same time, you will avoid much delay, and your prospects, in consequence, will become much brighter. As 6-inch and 7-inch pots are both very small in which to flower vigorous-growing Chrysanthemums, we advise you to repot the plants now in 6-inch pots into others measuring 8 inches across. The same rule also applies to those growing in 7-inch pots; they should be shifted into others measuring 9 inches in diameter. As your object appears to be that of making your greenhouse or conservatory bright and pleasing in the late autumn rather than that of exhibiting the blooms, you may, even at this protracted period, carry out the final potting with every prospect of success. The sooner the potting up is done, however, the better, as the buds will be developing within another month.—E. G.)

Watering Chrysanthemums.—No one knows more the amount of trouble watering entails just now than the grower of a batch of Chrysanthemums in pots, and anything that will help to minimise labour is worth considering. It often happens that watering once a day will not suffice. A good plan, instead of standing the pots on a bed of ashes, is to slightly submerge the pots, say, for 2 inches or 3 inches, as by this means much of the moisture is retained, whereas if the pots are placed merely on the surface, a deal of the water drains away. I have found it lessens labour considerably if, between the rows of pots exposed to the sun all day, a board is placed at the front, and often shelves that are used in the greenhouse in the winter may be temporarily brought into service. Old tan, where it can be obtained, if spread about the pots and watered, will keep moist a long time, and save the water-pot. Either of these methods is preferable to placing the plants under the shade of trees, for, after all, one must not forget that wood ripening is essential to the formation of the best blooms, and if plants are kept shaded for any length of time, one cannot expect this to take place. Weak liquid-manure applied from time to time will help the plants, and a change of food is appreciated more by Chrysanthemums, perhaps, than almost any other plant. The fault lies in giving the nutriment too strong. It is much better to give liquid-manure weak three times than surfeit the plants with a first application.—TOWNSEMAN.

Summer Stocks.—In the small but beautifully kept cottage garden of a police-constable in the village of Hambledon, Surrey, I saw the other day a singularly beautiful collection of summer Stocks. There were several colours, and about three score of plants in the bed, which was placed near the back door, and formed a sort of advance border to the vegetable garden beyond. The plants had been raised by sowing them in respective colours in a shallow box placed in a frame, then putting them out equally mixed. It would have been difficult to find from any simple flowers more of charm or richness of perfume. Stocks are in very great variety, but those of pyramidal form seem best suited for garden culture. They bloom a long time, and well repay cultivation. In the case mentioned nearly all the plants had double flowers, so great is the proportion of doubles now furnished by any good strain.—A. D.

ROSES.

ROSE LA FRANCE.

There is probably no Rose so popular as La France. Its noble silvery-pink flowers, of beautiful form, are in much request, and when culled with long stems and arranged in a vase it is impossible to exaggerate their great beauty. A Rose is not merely popular because it is a beautiful flower. Something else is required before it attains to that distinction, and that is vigour of growth, combined with freedom in blossoming and

shoots should be left a considerable length. I have seen this variety grown splendidly against a fence, as in illustration, its growths being allowed greater freedom than is usually accorded, and I am persuaded La France would be an excellent Rose for a wall 5 feet or 6 feet in height. As a standard La France makes a glorious head, which, if kept well thinned in the centre, produces blossoms of the highest quality. In large gardens it is not unusual to meet with La France by the hundred, and, where practicable, no Rose would so well repay the grower. But I would advise all about to plant the variety in hush

of the latter, not very distinct in the early summer, but towards autumn the difference in the two is well marked, Duchess of Albany being then nearly red, and in the forcing-house I have cut flowers almost as bright as General Jacqueminot. All three are first-rate Roses for pots, either forced or grown in cool greenhouse or pits. By potting up a number of each in the autumn, a supply of lovely Roses is assured in April and May, even without artificial heat. There is a Climbing La France, which produces fine vigorous growths as young plants, but it is very apt to revert to the dwarf type. There is also a

Rose La France on own roots.

hardiness. That La France possesses these qualities will not be denied. I know of no Rose that makes a more beautiful standard, and for planting in groups this old variety has yet to be surpassed. Moving, as I do, freely among Rose growers, I find the demand for fragrant Roses much on the increase, and this good old kind is one of the sweetest. La France should be treated almost as a Tea variety in the matter of soil—that is to say, it does not care for a strong, rich soil, as in such a manner, which is anything but beautiful. It should not be hard pruned. I believe in well cutting out old wood, but this one year old

form to obtain it on the seedling Brier if own-root plants cannot be procured. This stock induces a fine autumnal growth, owing to its deep rooting character. Some individuals have been disposed to underrate La France and to extol Caroline Testout; but, whilst granting all that can be said in favour of the latter, I still think La France stands unrivalled among pink Roses.

The white sport is a Rose to be looked after. It is called Augustino Guinoisseau. A more showy nearly white Rose we do not possess. It has all the good points of La France, excepting that it is not so full or perfect in form. Many is a highly coloured sport

Rose named La Franco do '89, but it is in no way connected with the variety under notice.
Rosa.

NOTES AND REPLIES.

Yellow Roses to grow near a town (H. Cox).—Rose growers are still waiting for a yellow Rose of a good hardy nature, and until that appears we must rest content with such as we have. A clay subsoil is not good for this type of Rose, but you could alter this somewhat by adding some road-grit and burnt earth to the clay before planting. If you prepare the soil in September, taking care to

dig it deeply and thoroughly incorporate the materials mentioned together with some well-rotted manure, you will be able to plant in November such Roses as we name with fair prospects of success. Many of the best yellow Roses are extreme growers, and would be all the better for a south or west wall. Failing this they succeed well as half-standards, or even as bushes, but in the latter case they should be planted 4 feet apart, and their growth bent over and attached to pegs inserted in the ground. We have marked with an asterisk the kinds that are especially strong in growth. There is one Rose everyone who has a garden should grow, and that is the new Soleil d'Or. On the tree or bush the flowers look like large flattish blood Oranges. It is a variety of great merit and is an autumn bloomer. Other extremely hardy kinds are Persian Yellow, Harrisoni, and Rosa lutea, but the quality of blossom is of no great order. The following are all splendid kinds, with more or less true yellow in them, although some are largely buff, orange, and bronzy tints. We place them in order of merit: *Gloire de Dijon, *W. A. Richardson, *Bouquet d'Or, *Celine Forestier, *Belle Lyonnaise, Mme. Charles, Marie Van Houtte, Mme. Hoste, Billiard and Barre, Jean Pernet, Mme. Ravary, Anzouze, *Mme. Barthelomy Levet, *Josephine Bernacchi, *Réve d'Or, Francisca Kruger, and Gustave Regis.

Rose leaves injured (Hugh Bright).—The leaves of the Roses you send have been eaten by the grub of the Rose saw fly (*Hylo-toma rosarum*). The grubs mostly become chrysalides in the earth, so that it is best to remove the soil from under the bushes to the depth of about 3 inches, and burn it or bury it not less than 1 foot below the surface. The grubs should be picked off by hand, or the bushes may be syringed or sprayed with paraffin emulsion or Quassia extract and soft-soap. In the autumn cut off any shoots that appear to be withered, as they may contain chrysalides.

Hardy Roses for arches.—Last year I had some galvanised iron arches placed across a path with a lawn on one side, and on the other a rather cold, damp border under some palls with an eastern aspect, and edged with tiles. Celine Forestier, l'Idéal, Aglaia, and Josephine Bernacchi have died. Could you tell me the names of those Roses one sees in old-fashioned gardens with glossy, abundant, dark green foliage, and pretty little rosette-like flowers, perfectly formed (not the Rambler type), blooming in clusters, generally pale pink or white or blush? I want something very hardy and quick-growing. I already have Crimson Rambler, Félicité-Perpetue, and Aimée Vibert. Would Perle des Jardins and Blauil 2 be likely to succeed on the Grass side? (2) Would you also kindly tell me whether the burnt earth Dean Hole says is so good for Roses is the same as the red rubble used to drain paths?—SUNDIAL.

[The Roses you refer to are the Ayrshire and sempervirens groups. They are splendid for arches in cold aspects. Félicité-Perpetue, which you have, is one of the best. Flora is very good, also Bennet's Seedling and Virginian Rambler. A yet further selection could be made from Dundee Rambler, Ruge, Princess Marie, Leopoldine d'Orléans, and Queen of the Belgians. Where practicable, we should always advise wooden supports for Roses, instead of iron, as Roses seem to thrive so much better on wood. If the iron is painted it helps to mitigate any injurious effects from its use. Spurred Larch poles are about the best supports for Rambler Roses. You would do no good with Climbing Perle des Jardins, as it is only a wall Rose, but Blauil No. 2 should succeed. Vivid and Robusta are two first-rate hardy climbing Roses; so, also, is the old but brilliant Fulgens. Reine Marie Henriette and the old favourite Gloire de Dijon are as yet unsurpassed in many respects, both for arches and walls, and you should try Mme. Alfred Carrière. It is a superb climber, vigorous, free flowering, and quite hardy. The red rubble you see used for the paths is burnt earth, but it is burnt too fiercely. Burnt earth should be of a blackish colour to be of the most use as an improver of clay soils; but some of the red sample you mention would be of great value where the soil is of a stiff, clayey nature. It should be well incorporated with the clay in the process of trenching.]

Rose Frau Karl Druschki.—This new variety has been exhibited in excellent form at the recent shows, notably by B. Cant and Sons and Alex. Dickson and Son. It is

Rose of German origin, raised by Mons. P. Lambert, of Trèves. The flower is pure white and of exceptional size. Its form is deep, with pointed centre, a shape most desirable, especially for competition. It is said to be a Hybrid Perpetual, and certainly the leaves appear of that class. It is, however, thought by some to belong to the Hybrid Teas. But this matters little, as it is a good grower and free to bloom. Rose growers will do well to add this to their collections as soon as possible.—H. S.

GARDEN PESTS AND FRIENDS.

The Apple aphid (Miss Douglas Dale).—The Apple leaves are badly attacked, as only too many are this season by the Apple aphid. Cut off any shoots that are very badly attacked and burn them, then spray the tree with a solution of paraffin emulsion or any insecticide that has soft-soap in its composition. Be sure that the insecticide wets the lower sides of the leaves. In the winter spray the trees with a caustic alkali wash.—G. S. S.

Caterpillars eating Grapes.—I forward you some caterpillars that are eating my Grapes. Nearly the whole of the bunches are affected. It is surprising the amount of damage the caterpillars have done. I hunt them up each day. The Vines were scraped and painted over with Gishurst compound in the spring.—HORN.

[The caterpillars attacking your Grapes are those of a small moth—ono of the "bell-moths" belonging to the family Tortricidae. It is difficult to recommend any method of destroying this pest, but a pair of fine tweezers would be of great assistance in picking them off, as spraying with an insecticide would be likely to injure the fruit.—G. S. S.]

Brown scale on Myrtle.—What are enclosed eggs (?) found on branches and under leaves of Myrtle-tree? Are they injurious to the tree? Are they the cause of a sticky dew on some of the leaves as enclosed?—R. S.

[The leaves you send have fallen a prey to brown scale. You ought to scrape off any of the insects that are on the stems or shoots of the plant, then spray or syringe the trees with paraffin emulsion or Quassia and soft-soap. In the course of a few days spray again to make sure of killing any of the young that may have escaped the first application. Let the leaves fall off naturally. To cause them to turn as you say the plant must be in a very bad state, and evidently wants attention at the roots.]

Insects on Aquilegia (N. E.).—The insects attached to the Aquilegia seed-vessel are the chrysalides of the common "two-spotted ladybird" (*Coccinella bipunctata*). Your plants have evidently been attacked by green-fly, and the grubs, which have now turned into chrysalides, have not injured the plants, but have fed on the green-fly. The grubs are entirely carnivorous, and should be encouraged in every way, as without them and some other natural enemies our plants would be far worse off from the attacks of aphides than they are now.—G. S. S.

Apple-trees unhealthy.—I enclose some leaves and Apples taken from a bush tree which has always borne very fine fruit. The Apples this year are all similar to the enclosed. The tree has scarcely grown at all this season. Can you tell me what is the matter?—H. C. Bova.

[The leaves of your Apple-tree are very badly attacked by the Apple aphid (*Aphis mali*) and by some caterpillars, none of which, however, I could find on the leaves. The late cold spring and the injury to the leaves by the aphides together have had an injurious effect on the tree generally, so that I should be afraid that the fruit would not attain its usual size, and will be more likely to be attacked by some fungus. However, the present weather is all in its favour. Spray the tree with a solution of paraffin emulsion, taking care to wet the lower sides of the leaves.—G. S. S.]

Wood wasps (Sirex gigas).—I enclose you in a box with this an insect I have found on my garden path. It is one of two or three more that I have seen within the last day or two. This spring I have had several rustic arches made in the garden; the uprights are of Larch and the tops of Oak. As I have never seen a similar insect here before, I think it probable that it comes from either one or the other of those woods, especially as they were always close to the arches. You will please notice in the corner of the box a chrysalis. This is, or rather, was a very prettily-marked hairy caterpillar I found on an Apple-leaf, which it had nearly finished. In sending you this information, may I thank you for the answers you have sent to my previous enquiries.—MORNON.

[The insects you find on your path, and of which you send a female specimen, come, as you imagine, from the Larch uprights that you have recently erected. They are commonly known by the name of "Wood Wasps" (*Sirex*

gigas). They belong to the same order as the wasps, but are by no means nearly related to them. Though they are dangerous-looking insects on account of their apparently formidable sting, they are quite harmless, and the organ that looks like a sting is merely the instrument through which it lays its eggs and places them in a hole in the wood. The females lay their eggs in newly-felled Larch or Fir timber, and sometimes in living trees that are in an unhealthy condition. I cannot tell from the chrysalis what the caterpillar was; chrysalides are so much alike as a rule.—G. S. S.]

Canterbury Bell falling.—I enclose a specimen of Canterbury Bell, and will be glad if you will tell me the cause of the plants drying up and going brown? I opened up the stem of one or two, and find that there is a curious fungus in the inside, which when quite young is white, but turns black and seems to absorb the sap. None of the other plants in the herbaceous border have suffered, and not all the Canterbury Bells.—M. WILSON.

[I am sorry to say that I could not find any trace of fungus in the small portion of the stem of the Campanula which reached me, nor on the rest of the plant. If you would kindly send up another specimen, with the stem not split open, I should be glad to tell you what I can about it. The fungus may not be the cause of the death of the plant, but be growing on the already dead tissues. I should rather imagine, from the look of the leaves, etc., that there was something wrong with the roots; but you may have already looked to that.—G. S. S.]

Preparing weed-killer.—In your issue of July 15, 1901, your correspondent "P." gave a recipe for weed-killer. I have lately tried it without success, because, after much boiling, I find a great quantity of large crystals settled down undissolved at the bottom of the boiler. What are these crystals, and how long does the mixture require boiling for the chemicals to be completely melted? Also how long will this weed-killer keep without deteriorating in strength?—A. S. R.

[The crystals you find at the bottom of your boiler are those of the arsenic which have not dissolved properly, owing to there not being enough muriatic acid in proportion to the arsenic. Try making the mixture as follows: Put $\frac{1}{2}$ lb. of arsenic into the pint of acid, then gradually add more until the acid will not dissolve any more. Dissolve the sulphate of copper in a little warm water, and then add it to the acid and dilute it with water as directed. This method will save the trouble of boiling, and will, I believe, be quite as efficacious.—G. S. S.]

Insects on Hop-leaves.—Can you tell me the name of the pale insect I send you something like caterpillars? Is it probable they eat the lice on the Hop leaves? There are some nearly white eggs on one leaf which somewhat resemble those of the ladybird, but are of a different colour.—VERONICA.

[The pale insects you send are the grubs of one of the "Hoverer-flies" belonging to the genus *Syrphus*. These grubs feed on aphides, and are of incalculable value to the cultivator of plants, as the number each will destroy in the course of a day is astonishing. The flies are rather more than $\frac{1}{2}$ inch in length; their bodies are dark, banded with white or yellow. They may often be seen hovering, almost motionless apparently, in the sun near trees or in some sheltered place. Their chrysalides are small, pale, Pear-shaped, and are about $\frac{3}{10}$ of an inch in length. The eggs I can say nothing about, as when they reached me there were only the shrivelled shells.—G. S. S.]

The Death's-head moth (Mrs. Butler).—The insect that you found in your garden is the caterpillar of the "Death's-head moth" (*Acherontia atropos*). These caterpillars, which are not uncommon, but never abundant, are usually found feeding on the leaves of the Potato, but they also feed on the Jessamine and Nightshade. The moth is probably our largest insect. The name "Death's-head moth" has been given it on account of a marking on the body just between the wings, which much resembles a skull. The wings of the moth measure from 4 inches to 5 inches from tip to tip when they are fully extended, and the head and body measure quite 2 inches in length. The fore-wings are of a dark brown colour with tawny markings, the hind wings yellow with two dark bands, the front part of the body dark brown with a yellow skull-shaped mark on it, the rest of the body yellow banded with black. When fully grown the caterpillar buries itself in the ground and becomes a chrysalis, in which condition it remains all the winter.

INDOOR PLANTS.

THE MALMAISON CARNATION.

Few, if any, plants are more admired than a batch of these lovely scented flowers when well cultivated and their foliage entirely free from spot—a disease so frequently attacking the Carnation, especially the one under notice. To do the plants justice a spon-roofed house should be set apart for them, as they require special treatment, though at times we find a small batch the picture of health and grown with a mixed collection of greenhouse plants. These are isolated cases, and the plants sooner or later succumb to the dreaded disease. The accompanying illustration shows a small group in vigorous health and nicely flowered, and as layering time is now with us, we will take our starting point from here, and give in detail their requirements up to their flowering period next year.

LAYERING.—As soon as the plants have passed out of flower, prepare a bed of light, sandy soil, with a fair amount of partly-decayed leaf-soil, 12 inches or so in depth, placed in a shallow frame. Knock the plants out of their pots, and set the plants out in the prepared soil, laying them on their sides, so

cow-dung or old hot-bed manure, with a good sprinkling of coarse river sand, with a dash of soot, will form an excellent compost. Carnations enjoy being potted moderately firm, using clean pots, thoroughly drained. Place the plants back in the frame again, and water, keeping the lights shut down and shaded for two or three days. The plants will soon make a fresh start, when afford full ventilation day and night.

REPOTTING.—Shift into 7-inch and 8-inch pots as soon as the roots are found to be working nicely down the sides of the pot. Towards November, as the dark days and long nights come, remove the plants to a light, airy greenhouse, and not too far from the glass roof, standing the pots on ashes or shingle, when very little water will be required until the days begin to lengthen. Too much care cannot be taken that no water is applied until the plants actually require it. Very little fire-heat is necessary; just enough to keep out the frost and the atmosphere of the house dry during wet or foggy days, as it is usually then that the spot on the grass appears. Dust lightly with flowers of sulphur on its first appearance, finally removing the foliage if it shows signs of spreading. Fumigate weekly to prevent green-fly making a home in the centre of the growths,

Royale de la Malmaison, or whether they obtained the name from having been grown and appreciated therein, is as a matter of history obscure, but in any case, whatever or wherever their origin, the fact remains that at no period of their history were they so variable or so splendidly grown as they are in British gardens to-day. In many of our best gardens, large and small, Carnation houses are considered as necessary as vinerias and Peach or Orchid houses, and the so-called Perpetual or Tree Carnations, and the superb Malmaison varieties, known by their enormous Rose-like blooms and broad curled leafage, are therein to be had in flower all the year round. These flowers are also much grown by market gardeners and florists, and rarely fail to bring a good price in the market, especially early in the year. Now and then on warm soils near the sea the common old blush Malmaison grows, and flowers fairly well in the open air, but the shelter of a cool and airy greenhouse is essential in order to obtain the finest and most perfect blooms. Extremes of temperature and moisture are alike detrimental, in winter a minimum temperature of 50 degs., with a rise of 10 degs. to 15 degs. during the day-time, suits them best, with a free and abundant circulation of fresh air. Fresh layers should be put down every season after blooming is over, so as to keep up a succession of sturdy young plants. The best compost consists of good fibrous loam, to which may be added soot or wood-ashes, sea sand, and old limo rubbish, and the pots should be well drained, anything like stagnant moisture at the root being fatal to their well-doing. A dose of weak soot water is useful now and then during spring and summer as growth progresses, and helps to destroy wireworm and other enemies in the soil. Lime water also is beneficial in checking worms and increasing the health of the plants. The old blush Malmaison is the earliest known, together with its pink sport, but of late years many very distinct and handsome varieties in this section have been raised.—*Field.*

Malmaison Carnations. From a photograph sent by Mrs. Norman, Holly Hill, Ditchingham.

that the growths can be easily pegged down. The common Bracken Fern does well for the purpose. First trim off the bottom leaves, leaving six to ten near the top of the shoot, then with a small sharp knife make an incision on the under side below a joint, bringing the knife upward through the said joint. Holding the layer still in the left hand, get the peg with the right and press the same gently but firmly into the soil, slightly raising the growth upward, but not enough to try it when it has been partly severed, or it will snap off, and cover with an inch of soil when it has been pegged down. If the soil be fairly moist no water will be necessary for a couple of days. A gentle dowing overhead with the syringe twice each day will suffice. Place on the lights, tilting them a little at the back, and shade during the brightest part of the day for a couple of weeks, but discontinue as soon as the layers begin to form roots, applying water when necessary with a small rose can, so that the soil is not washed from the layer. In from month to six weeks the plants ought to be ready to pot up, carefully severing each one from the parent plant with a sharp knife, and preserving all the roots and soil attached thereto, and placing in 4-inch to 6-inch pots, according to vigour of plant. Good fibrous loam, fairly lumpy, two parts, one part half-decayed leaf-soil, and one part well-decayed

and avoid cold draughts. No pinching of the shoots must be practised, and a neat stake should be put to each growth betimes. If extra fine blooms are desired, the side buds must be removed, only retaining the centre one; but, to my mind, this spoils the look of the plants, so I let them all come to perfection. Avoid too moist an atmosphere overhead while in bloom, as the petals are quickly spoiled if it is allowed to settle on the flower. A little clear, weak soot-water given once a week tends to give the foliage that beautiful dark green tint always prevalent with healthy plants. Some cultivators grow on part of their stock for another year, selecting the healthiest of those in the smaller size pot, reducing the ball a bit and moving into 8½-inch and 8-inch pots, and growing on as before mentioned. My best results have been with a fresh layered stock each season, discarding any that lack health and vigour. Of recent years several new varieties have been given us, all more or less beautiful, and should be given a trial where variety is enjoyed, though few, if any, is likely to oust the old favourite flesh-coloured Souvenir de la Malmaison for purity and fragrance. J. M. B.

How, when, or whence these exquisite flowers were introduced to British gardens no one now appears to know. Whether they really originated in the once celebrated Jardin

NOTES AND REPLIES.

The Dodder on Pelargoniums.—I shall be very pleased to know what caused it. It grows on the leaves of Geraniums and finally kills the plants.—*Nemo.* (Your plants have been attacked by the Dodder (*Cuscuta*), a parasitical annual which attaches itself to the plant on which it grows, and into the texture of which it sends out aerial roots at the point of contact, and through these imbibes the sap of the attacked plant.)

Hanging baskets.—Baskets that hang from the roof of a greenhouse or balcony, or are suspended in a house window and filled with flowering plants, should now be in the zenith of their beauty, and it is, therefore, most desirable that one should keep them in good condition as long as possible. Most of the causes of failure with hanging-baskets arise from forgetfulness on the part of the owner to water at the right time, and this occurs often amongst those whose occupation calls them from home during the middle of the day, when the heat is most trying. The advice so frequently given—to take the baskets down and immerse them in a tank of water whenever they need it—cannot well be improved upon.—*WOODBASTWICK.*

Cinerarias in frames.—Young plants of Cinerarias often die off in the summer when in frames through being kept too long in one pot, instead of giving them the needful shift as soon as they are ready. When they show signs of the lower leaves turning yellow, and thrips commence to attack them, it is high time attention was given them. Cinerarias, least of any plants, should not be allowed to get into a neglected condition, as one can rarely make good any deficiency in this direction by subsequent treatment. Encourage growth by watering and syringing, keeping their roots cool by plunging the pots in ashes and shading them from hot sun. Steady growth with coolness just now is most essential.—*LEAFHURST.*

Bouvardias.—Should any plants require a shift it is not too late to repot, using good loam, leaf-soil, and a dash of sand, with a small quantity of peat if the loam is inclined to be heavy; potting firmly, and keeping under glass for a fortnight, when they should be stood out in a partially shaded position during the

next month. Those that do not require fresh pots should be put out at once, and towards the end of August the plants ought to be moved to a sunny aspect, where the growth may have the chance of ripening up, without which a full crop of flower cannot be expected during November and December. Secure the growths to a neat stake, and pinch out the point of the strongest shoots up to the middle of August, when no more stopping should take place. Clear weak soot-water is a good stimulant for Bouvardias at the roots, and is a good thing for syringing overhead with after hot days, this doing the plants a deal of good and warding off birds and red-spider, both of which will attack this plant if at all neglected during summer.—J. M. B.

Growing Calceolarias.—I was much interested in the article on Herbaceous Calceolarias, by "J. M. B.," in a recent issue of GARDENING ILLUSTRATED. He has given a capital simple account of the culture of Calceolarias. I have grown them from seed for some years, and have flowered a grand lot of about 150 to 200 plants in a cold-house this year, which are just over. Each plant was quite 22 inches high and about 16 inches wide. They were in flower about eight weeks, and the sight was magnificent. It is strange more amateurs do not grow them. If I might add anything to "J. M. B.'s" remarks, I might say that a good strain of seed and careful watering are the great secrets in growing Calceolarias. Never water unless they want it, but do not let them get dry.—E. H. H., *Heywood, near Manchester.*

Fuchsias for autumn.—In order to have nice little plants for blooming late in autumn, cuttings should be struck now. Put them in sharp, sandy soil, and keep them for a week or two under a handlight or bell-glass in any house or cold-frame where they can have shade and be kept moist by an occasional syringing, and they will soon strike root. The shoots that form the best cuttings are those that are strong and short-jointed. As soon as rooted it will be necessary to pot them out at once in order that they may have no check. For growing Fuchsias nothing answers better than rich fibrous loam with a little leaf-soil or very rotten manure added. In this they should be potted somewhat loosely and kept in a close pit or frame to give them a start. As soon as they get well hold of the soil they may at once be moved to a shady situation out-of-doors, as though the growth will not be so rapid, what they make there will be shorter and firmer, and compact little plants that flower freely are always the most valuable, as they come in for vases in rooms and window embellishment, purposes for which small Fuchsias are specially well adapted. To keep the roots uniformly moist when the plants are grown out-of-doors it is a good plan to plunge the pots in littery strew or some other non-conducting material, which should be wetted from time to time by watering the Fuchsias overhead after the drying heat of the day. This damping will refresh them greatly and help to keep them clean, as well as assist them in their growth, and to make them compact and symmetrical they should be stopped once by having the points of the side shoots nipped out, when they will soon branch and form perfect little pyramids, a shape which is the most suitable for Fuchsias. Plants raised from cuttings now and treated in the manner here specified will not only be most valuable for the autumn, but they will be of great use for starting early to make compact specimens the following spring.

Begonias fading.—I have some single Begonias in a fairly rich bed in the open air. As fast as the leaves form rusty spots appear, which decay into holes, and the leaf thus dies. I enclose a specimen leaf, and shall be obliged if you will inform me the cause of the rust and how to prevent it? The plants have not been watered in sunshine, so the rust can hardly be caused by a blister.—PADDY.

[Your plants are attacked by the Begonia rust, which for the last six or eight years has given a good deal of trouble in various parts of the country. Like other subjects (Fuchsias, for instance) originally natives of South America, they are more satisfactory in a cool, wet summer than when it is very hot and dry. The cause of the disease has been by different authorities attributed to minute thrips, fungus, and a microscopical oelworm, but considerable differences of opinion have been expressed on

these points. Of the various remedies tried, that which has given the greatest amount of satisfaction consists in giving the bed a good mulching of well-decayed manure and leaf-mould, for this class of Begonias is a liberal feeder. If this is done, it, in conjunction with the cooler nights that one may reasonably anticipate, will doubtless be a good way towards renovating your Begonias, and the late summer display may be better than you at present anticipate. This disease frequently comes on in a very sudden manner, and in several instances that have come under our notice it followed an addition of leaf-mould or other soil made to the flower-beds. Begonias of all sections are, particularly under glass, liable to be attacked by a very minute kind of yellow thrips, that cause the veins of the leaves and the points of the young shoots to become congested and the flowers to drop before expansion. They are very troublesome, but the result of their injuries is quite different from the ailment from which the leaf sent is suffering.]

FRUIT.

WATER MELONS.

WERE our climates warm enough to admit of the culture of Melons in the open air we should probably place a higher value on the Water Melon than we now do. In countries where the summer heat is intense, Water Melons are largely grown, and are considered wholesome as well as refreshing. The Water Melon,

The Water Melon.

being of strong growth, requires plenty of space, a single plant under favourable conditions covering many feet of soil. In favourable seasons in the warmer parts of this country it is probable the Water Melon would succeed, and considering its hardness and vigour we should do well, perhaps, to try it under glass, as it does not need much care, and bears freely. In any case early planting in rich, free soil, and copious waterings are indispensable. On the Continent it is planted out on gentle bottom-heat early in May, the plants being sheltered with bell-glasses until they become established.

•• SILVER-LEAF IN PEACHES.

As the season advances one may find in many gardens, both indoors and outside, traces of this disfiguring disease. As I have had to deal with the above disease several times in different gardens, a few remarks may not come amiss to those readers whose trees may be affected by it. As a rule, I have found it attack one branch first, and then if not taken in hand to gradually work all over the tree. When a tree is badly infested it has to the uninitiated the appearance of a severe attack of mildew, for which many amateurs often mistake it. Some few years back I took charge of the fruit department of a large garden in the north of England. In one of the late Peach houses was a very large Royal George Peach-tree, which, as I looked at it for the first time from the doorway, put me in mind of nothing so much as a Silver Birch trained to the trellis. As the tree was in such a very bad state the head gardeners had made

up his mind to replace it by another. However, he gave it another season's grace to see if I could do anything to eradicate the disease. Nothing could be done till towards the end of September or beginning of October. Drainage was perfect, as the subsoil was composed of nothing but sharp sand, which necessitated watering the borders daily throughout the growing season. As soon as the leaves began to fall the worst affected branches were eawn clean out, and the border over the roots pricked up with a fork, followed up by a heavy mulch of manure, with a good sprinkling of lime added. When the tree began to break in spring, feeding was carried out regularly three times a week, either with artificial manure or liquid from the farmyard. The young growth still had the same silver tinge, but in a much less degree, which was some reward for the trouble taken. By feeding often (and every now and then giving a sprinkling of lime, which was washed in by watering) right throughout the growing season, the disease died away, and the tree made new, clean growth. When the tree shed its leaves the disease could hardly be seen. The same treatment the following season gave very gratifying results, as the tree not only seemed to throw off the disease, but carried a few fruits to perfection. Since then the tree has behaved very satisfactorily indeed, and has not since, so far as I know, ever shown traces of the disease and always bore a good crop. From that time I have practiced the above on many trees, and seldom failed. The cause of silver-leaf, in my opinion, is weakness through overcropping and absence of lime; the cure, feeding well, perfect drainage, plenty of lime, and a medium crop. H. B. J.

NOTES AND REPLIES.

Mealy-bug on Vines.—One simple and yet cheap remedy against mealy-bug is hot water. This, applied at a temperature of about 120 degs., will destroy all that comes into contact with it, and will not injure the foliage of the Vines. To use water at this heat, the operator will need a cloth to hold the syringe, for this will soon become unbearably hot. Direct this hot water with as much force as possible to those portions on which the insects abound. It would not, however, be advisable to syringe the bunches direct when in a ripe state, but water falling on them from overhead leaves will not harm them. Bunches when cut from the Vine for use may be held under a hot water tap to wash out the insects and deposit. A time, however, when the most good can be done is after the Grepes are all cut, then the laterals may be shortened partially, so that there is less surface to deal with, and that remaining may be thoroughly treated. The water must be applied with all the force possible, as it is this jointly with the heat that does the work of destruction. Where much trouble has existed the walls, border, trellises, etc., must be treated on similar lines, for stray insects falling on the border or secreted in the walls or woodwork soon make headway and become re-established. When a remedy so cheap and yet so effective comes within the reach of everyone there is not so much excuse for having Vines badly infested. A touch with methylated spirit will quickly destroy any insects left.—W.

Pruning a Mulberry-tree.—You have an article on the pruning of Mulberries. I wish you would give all the pruning. I planted one two years since, and do not understand the best way of pruning it.—W. C. B. H. (In the case of the Mulberry, merely skin out any cross shoots where they are too thick. Any weak spray springing from the branches in the inside of the tree must be removed to admit sun and air.)

Plum-tree gumming.—I am enclosing a piece of my Grand Duke Plum as you asked me to send a piece later, thanking you for past information regarding the tree. The tree is on the south wall of the house in a country village.—J. LANGLET.

[You have, evidently, from the sample sent, been too free with the knife, causing the gumming from which your tree is suffering. Another reason may be that manure has been used too freely, thus causing a gross growth, which is liable to gum. Lift the tree in the autumn and apply some lime-rubble or old plaster to steady and moderate the growth, and the gumming will disappear. Nail in as much of the young wood as there is room for, if there

is any on the tree, and cut out all the bad wood. If too far gone it will be better to replace with a young healthy tree.]

Planting Strawberries.—I have a piece of land which I am desirous of putting Strawberry plants on this year. It is now in Potatoes, and I shall have it got ready for the plants in the autumn. It slopes gently to the south. The soil is stiff, and has always been noted for growing early fruit. Please tell me what sorts you think will be suitable to produce good-sized, early fruit, and what can do to induce the early growth?—W. BROWN-SMITH.

[To enable you to have fine and early fruit next year on your newly-planted Strawberries of the coming autumn you should select all the very earliest runners you can. Cut them from the old plants and dibble them out 6 inches apart into well-mannered soil, where in dry weather they can be kept well watered. They should then be strong and well rooted to plant out when the Potato crop comes off. But when you take off the Potatoes you should dig in deeply a further manure dressing, or otherwise after the first year the plants will do indifferently. If you have to purchase plants we fear you will not get them strong enough to give you fruit next year. Only quite early and strong runners will do that. The best market Strawberries are Royal Sovereign and Sir Joseph Paxton. Earliness to bloom and fruit after all depends chiefly on position, absence of frost, and general nature of soil.]

TREES AND SHRUBS.

NOTES AND REPLIES.

A yellow Rhododendron.—In your issue, week ending July 12, a correspondent referred to a yellow Rhododendron exhibited by M. Moser, of Versailles, at the Paris flower show in May. I wrote to M. Moser, and enclose his courteous reply. It may save other readers from being misled, for though doubtless lovely as an Azalea, it will not suit where the evergreen one is required.—A. BAYLDON, *Dartich, S. Devon.*

The Azalea pontica Baron Ed. de Rothschild, though having the umbels of flowers as big as those of some Rhododendrons, is like the usual forms of *Azalea pontica*, with deciduous foliage.—RENE MOSER.

Abutilon vitifolium.—This cannot be called quite hardy, perhaps, but when it has withstood 12 degrees of frost several nights in succession and no harm is done to the plant it may certainly claim to be half-hardy. In the grounds here, sheltered by trees, it has reached nearly 16 feet high, and during the month of June was a sight not soon to be forgotten. Its lovely porcelain-blue, Mallow-shaped flowers caught the eye of all visitors, some thinking it was an Hibiscus. It can be increased by cuttings in early spring or in the autumn by giving close treatment under a handglass and protecting from frost. Should any pruning be required, it is best done early in the new year, before growth commences.—EAST DEVON.

Quick-growing trees for shade.—Would you kindly give me the names of some common English trees which would be of the quickest growth and give the greatest amount of shade, as I am meditating taking a new house in a bare locality? The names of any quick-growing ornamental shrubs and the general treatment of each would be of great value to me.—WIDRICK.

[Quick-growing trees that can be recommended for such a purpose are: *Acer platanoides* (Norway Maple), *Acer pseudoplatanus* (Sycamore), *Ailantus glandulosa* (Tree of Heaven), *Fraxinus excelsior* (Ash), *Platanus acerifolia* (Plane), *Populus alba* (White Poplar), *Populus canadensis* (Canadian Poplar, one of the most rapid growing of all), *Populus fastigiata* (Lombardy Poplar), *Populus tremula* (Aspen), *Tilia vulgaris* (the Lime). Of evergreens: *Pinus austriaca* (Austrian Pine), *Pinus Laricio* (Calabrian Pine), *Pinus arcolata* (Himalayan Pine), *Cupressus Lawsoniana*, and *Thuja gigantea*. Of shrubs or small trees there are: *Berberis stenophylla* (Golden-flowered Barberry), *Colutea arborescens* (Bladder Senns), *Deutzia crenata flore-pleno*, (*Double-flowered Deutzia*), *Forsythia suspensa*, *Laburnum*, *Negundo fraxinifolia variegata* (variegated Negundo), *Philadelphus coronarius* (Mock Orange), *Philadelphus grandiflorus* (Large-flowered Mock Orange), *Ribes cereum* (Flowering Currant), *Sambucus nigra aurea* (Golden-leaved Elder), *Syringa (Lilac)* in many varieties, and *Weigelia*, all quick-

growing shrubs whose flowers run from white to crimson, some of the pink forms being very pretty. All the above-named shrubs are deciduous. While the above-named may be taken as the best in their respective classes, the list might be considerably extended; but from the tone of your letter we have, we think, given as many as you require. Planting may be done from the beginning of November onwards. In purchasing the plants take care that they are clean-grown, healthy stuff and have been transplanted within the last two years, as they then feel the check of removal less than if they have been long established in one spot. In most nurseries they are frequently shifted to insure them to the change. In planting, take care that the holes are sufficiently large to accommodate the roots without cramping them, and see that the soil is made perfectly firm all around. If the planting is done rather thickly at first for the sake of shelter, do not hesitate to thin out some of the least important if they become at all overcrowded.]

Wild single Roses and common Honey-suckle.—These have been a mass of bloom in our country lanes for many weeks during this summer. Those of us who are always mixed up with cultivated plants (good as they may be) find a relief in the flora of our lanes and ditches, and I often think we in the west have a great wealth of them. The wild Rose has a charm quite its own. This is seen when a large mass in full bloom stands amongst or is backed up with other greenery; added to this, all formality is gone, and the many shades of colour are noteworthy, from pure white to brighter shades in pink and red. Their beauty is increased when they have as a companion the Honey-suckle, which is often met with in West Dorset. Bright pink Roses and yellow Honey-suckle associate well together, and when seen climbing up the side of a tree or big Thoro-hush present a sight not easily forgotten. In many of our lanes the air is loaded with the sweet perfume in the evening. Everyone loves the Woodbine, and where it is possible it should find a home in the garden. Recently I saw it growing at the foot of two stone pillars by a lodge gate. A wire was placed round to tie the main stems to. In a private garden near Yeovil about the same time I saw it growing as a standard in mixed hardy plant borders with good effect, and a recent correspondent recommended it for pots, a purpose it must be charming for. Many of our pleasure grounds would benefit by more of these two shrubs and fewer of the common Laurels.—J. CROOK.

BOOKS.

"ROSES FOR ENGLISH GARDENS."*

THERE are so many books on the "Rose" that we doubt if another were wanted much, and fear this book has not arisen from the hearts of the authors—capable as the authors are—or the needs of the public so much as from a desire to use up a number of illustrations. There are far too many of these, and they are a great deal too much alike. In one case there are as many as twelve pages of cuts together, without a word of any kind between; in another case there are eight, in another six, and in another nine. We have never seen anything like this before, even in these days of process cuts. The list of the best Roses at the end is far too limited, and some of the very best are omitted. The stupefying division of Roses into "garden and exhibition" is kept up, although Mr. Mawley nullifies this by saying that in some cases the Rose is both an "exhibition and a garden" one. There is nothing more ensnaring to a certain kind of mind than false and needless definition, and there never was a more foolish one than the division of Roses into "garden and exhibition." There have been so many garden books issued of late that we hope the publishers will be a little more careful, especially in making books on subjects that are already overdone. In this book, which is pretty and well printed, there is no information that is not already abundantly to be had in the works of Dean Hole, the Rev. Foster-Melliar, and other writers.

* "Roses for English Gardens," by Gertrude Jekyll and Edward Mawley. Geo. Newnes, Ltd., 7-12, Southampton

GARDEN WORK.

Conservatory.—Bush Chrysanthemums should be pinched for the last time. If pinched later the flowers may be more numerous, but they will be smaller. Those plants intended to produce large blooms should have all side shoots regularly removed. In some cases premature buds have been formed. These, of course, will be removed, as the blooms will be useless. Rich top-dressings should be given when the roots have occupied all the soil, and weak liquid-manure may be given when necessary, but avoid over-feeding, as the growth must not be rushed. The plants must be securely staked and not crowded; there must be room to move freely among them, to do the necessary work. Earwigs will probably be troublesome, and must be sought for diligently and destroyed. Hiding-places can be made for them among the foliage, using sheets of paper crumpled up and placed among the branches. Pieces of white rag, about the size of a pocket-handkerchief, used in the same way will be even more useful than paper, because more lasting. There is one disadvantage in using Bamboos as stakes for Chrysanthemums—they are neat and lasting, but being hollow the earwigs creep into the cavity at the top and wait there till they are hungry. A stout piece of wire thrust into the hole during the day when they have retired will kill them, or, if preferred, the hole may be stopped with a small plug of wood, effectually closing the orifice. A group of Cannas when well grown is attractive from this onwards through the autumn, but the plants must have good-sized pots and the soil should be rich, though this may be made up with liquid-manure when the plants have made roots abundantly. I was reminded the other day of the value of the Fig-Marigold (*Mesembryanthemum*) by seeing a well-flowered, drooping plant among a group of plants at a cottage garden show. These have disappeared from better class gardens, but occasionally a plant or two may be seen in cottage windows in the country, and very pretty they are in a sunny window. More than three hundred varieties have been catalogued, and now that South Africa is being opened up it might pay someone to introduce them again. They are very charming, and are not difficult to propagate and cultivate. They are nice for baskets and brackets.

Stove.—Do with as little shade as possible now, and ventilate more freely to keep down temperature. This will ripen and harden the growth. Orchids which have completed their growth may be moved to a house with a drier atmosphere. *Dendrobium* and *Calanthes* will do in a vinery or a rather deep pit, lightly shaded. In the vinery the foliage of the Vines will afford sufficient shade. The young winter-flowering stuff will do best now in pits, lightly shaded for two or three hours in the middle of the day. Do not crowd anything now, either in pits or houses. It will be better to grow fewer plants than draw things up weakly by overcrowding. Watering is always important work, and should never be left to inexperienced hands, as, though there is less danger of overwatering now than in the winter, yet it is sometimes done. Specimen plants should be looked over twice in the twenty-four hours, and apply the usual test of tapping the sides of the pot. Clear soot-water may be given to Gardenias. Anything which requires more forcing stimulant may have a weak solution of any of the plant foods in the market, of which there are now many, all more or less good. Soft water in a time of drought is generally scarce, but the necessary atmospheric moisture at such times may be supplied by frequently damping the floors. No fire-heat will be required now.

The late vinery.—Scalding sometimes happens to closely-stopped Vines, and such kinds as Lady Downe's, Madresfield Court, and other Muscats, which sometimes scald when the foliage is much curtailed, will require careful management. The true remedy is to leave plenty of foliage without unduly crowding and ventilate freely, especially early in the morning. In the case of Vines which have been too closely stopped, a light shade may be used on very hot days. Forcing-houses of modern construction contain less wood

and more glass than older structures and require more care in management. In very light structures with large squares of glass the Vines should be dropped a little further from the glass; 18 inches will be none too much, and I have known houses where even this distance has been exceeded with advantage. Vines are gross feeders, and where the borders are as well drained as they ought to be it is not likely they will get too much water. The season, as regards the temperature, has been very fluctuating, and it is well to be ready to apply a little fire heat when the cold change comes.

Ferns under glass.—Seedlings should be pricked off thinly into boxes, and young plants which have acquired some size in boxes should be potted off singly. There is no better place for young Ferns during the next month or six weeks than a pit or low frame on a bed of coal-ashes, shaded from bright sunshine and kept moist. Maiden-hair and other Ferns which will have to supply fronds for cutting during autumn and winter should be freely ventilated and not too heavily shaded, so that the fronds may be hardened. Plants in 5-inch pots which have filled the pots with roots may have a shift into 6-inch pots. At least half the compost should be good, sound loam, and they should stand thinly, so that there may be room for full development. Ferns in baskets will require a good deal of water now, and if hard water has to be used, let it stand in the sunshine for a few hours to soften it.

The early Peach-house should be very freely ventilated now that the fruits are all gathered. If possible, remove the lights, and by complete exposure thoroughly ripen the wood. The night dews and showers will be beneficial, and see that the roots are moist.

Window gardening.—Begonias are a strong feature now. The old variety Weltonensis is a favourite cottage-garden plant. I have noticed Tuberosus Begonias in several window-boxes are doing well and attracting a good deal of attention. They want rich soil and careful watering in north aspects. The Mimulus family are useful, especially the spotted hybrids, which grow freely and hang over the sides of the box. Indoor Palms, Ferns, and Aspidistras are cool and resting to the eyes. For suspending we have the Campanulas.

Outdoor garden.—If it should be necessary to sow seeds of any kinds in hot weather, soak the ground in the evening and sow in the morning following, and shade till germination takes place. Under these conditions all good seeds will germinate strongly. This is not at the moment ideal weather for budding, but the time for such work is early, and we can wait; or, if there are only a few stocks to do, a good soaking of water will start the bark, and the budding can be done in the evening or early in the morning. If one has young seedlings to prick out and the weather is hot and dry, soak the ground in the evening and plant on the morning following. Shade can be improvised by sticking a few branches among the plants. These will suffice, either till the weather changes or the plants are established and require no more help. These are details that we have often found useful when dealing with such things as hardy Primulas and Forget-me-nots, which acon perish if disturbed in dry, hot weather. Oriental Poppies are very bright whilst they last, but soon get shabby after the flowers fade. They are very bright among shrubs, and, if Chrysanthemums are planted near, they will take their place now. Hardy early-flowering bulbs, such as Crocuses, Snowdrops, and Narcissi, may be lifted and sorted now, ready for planting next month.

Fruit garden.—One of the most important jobs just now is securing a stock of Strawberry runners for forcing and planting. This has not been a good season for the market grower, though those who grow late sorts may do better. Royal Sovereign is the best early kind. This season the frost cut the early blooms and made the gathering backward, and it clashed with Paxton, and a glut was created when the hot weather set in. Latest of All is a good bearing kind, but the want of colour is against it, though the flavor is not so bad.

Something more might be done with Elton Pine for late use. Sir C. Napier is a good Strawberry and there is never a glut of British Queen. In some gardens I visit, Apples and Plums are very plentiful, chiefly on young trees planted from eight to ten years. From this onwards to twenty years is the most profitable time for fruit-trees. Before and after the crop is often scanty. A good deal may be done to help young trees by judicious top-dressing, or mulching with anything which has any manurial value. Keep the growth of open-air Vines thin and the fruiting shoots pinched back to one or two leaves. Where there is room, train up a young shoot that will replace one of the old ones in the near future. The summer pruning of wall-trees should be done now. Leave from four to five leaves, and then the hack eyes will not start, and may develop into fruit-buds for next season's crop. Remove all defective fruits from Pears and Apples. Lord Suffield Apple is in good condition now.

Vegetable garden.—Salt is a good dressing for land in dry seasons, especially for green crops. It is not so good for Potatoes, unless the soil is very porous. This season and last one could scarcely do wrong in applying salt to any land, for on all soils the crops suffered from drought. This season the crops have not suffered quite so much; still, the rainfall has not been sufficient for green crops on light or porous soils, and a pound of salt to the square yard would have had a good effect. Sow an early kind of French Bean on a warm border where it can be protected, and a further planting may take place a little later in a pit, with the lights off for a time. Sow Lettuces and Endive freely now; it is better to have too many than too few. Bath Cos and the Hardy Hammermith Cabbage are reliable kinds. Hicks' Hardy White Cos and All the Year Round Cabbage are also good, and every gardener knows what a good little Lettuce Wheeler's Tom Thumb is. Make a fresh sowing of Spinach and winter Onions. Sow a few more Cabbage seeds of a good early kind, and a full crop of Turnips for winter use should be sown now. E. HOBDAV.

THE COMING WEEKS WORK.

Extracts from a Garden Diary.

August 4th.—The surface is freely stirred among Winter Greens, Turnips, Lettuces, Endives, etc. Tomatoes outside are regularly trained, and the surface between the rows freely stirred. The bottom trusses are well set, but we shall stop the leaders when the tops of the stakes are reached and permit no further progress upwards. No flower-stems are permitted on Seakale. Root-cuttings make the best plants, and seeds are not sown. Sowed Chervil.

August 5th.—The ground for Winter Spinach and Onions has been dressed with soot and forked over, ready for sowing shortly; but a further sowing of Spinach will be made later, as this is an important crop. A little soot has been dusted over the Celery to keep off the Celery-fly. Pelargoniums have been cut down and cuttings inserted. We are also putting in cuttings of Fuchsias and early-flowering Zonal Geraniums. Those Geraniums intended for winter-flowering are outside, with all flower-buds picked off.

August 6th.—Sowed a few more seeds of Eillam's Early Cabbage. Planted Coleworts 10 inches apart, also Tom Thumb Savoy. Liquid-manure is given to Figs on south wall. The borders are shallow and well drained, and the Brown Turkey is carrying a good crop. A note has been made of Gypsophila elegans, which has been found valuable for light decorative work, even more so than the perennial variety G. penicillata. Shall further sow the annual variety in succession.

August 7th.—The beds of Geraniums and Petunias are very bright. We generally plant some Geraniums of the best bedding sorts in reserve beds for producing cuttings to save the beds, and those will soon be headed back and cuttings inserted. They will be rooted in the open air. Heliotrope Lord Roberts, of good habit, produces very large flowers and makes a good mass. Sowed seeds of Auriculas and

hardy Primulas in boxes in a shady frame. Budding and layering are continued.

August 8th.—We are waiting for rain for pricking off a lot of seedling hardy stuff, as we cannot face the labour of watering so many young things in a dry, hot time. Box edgings have been trimmed, and all evergreen hedges of Yew, Privet, and Box have been cut. The Box makes a very neat hedge in the garden. All houses where Grapes are ripening have been, as far as possible, cleared of plants, and after the last watering the borders will be covered with straw.

August 9th.—Herbs have been cut for drying and vegetablea gathered for pickling. All are gathered when dry. Strawberry runners are still being layered into pots, as we want many and cannot obtain enough at once. All summer pruning of fruit-trees has been attended to. Top-dressed Cucumbers in frames. We want to keep these going till beginning of October, and we generally have no difficulty in this, and by that time the first lot will be coming on.

LAW AND CUSTOM.

Trees growing over wall.—I have a garden surrounded by a wall, against which I have fruit-trees growing. The owner of the adjoining garden has planted Elder-trees, which grow high above the wall, and cast light on the fruit-trees. Can I insist upon his cutting them to level of wall or not?—H. F.

[You cannot compel your neighbour to cut the trees, but if he will not do the work you may do it yourself. Your best course is to give him written notice that if he does not cut the trees within a reasonable time—say within three weeks from the date of the notice—you will do the work yourself. If he fails to comply with the request you may properly do the work yourself. You may only cut those portions which are actually overhanging your land or growing in it. You may cut these portions perpendicularly over the boundary, but you must not cut further back than the boundary or you will be liable to an action of trespass. You will gather from this reply that you cannot lower the height of the trees—your neighbour may allow them to grow as high as he chooses—although, of course, if any of the upper branches overhang your land you may sever those branches perpendicularly over the boundary.]

BIRDS.

Death of Canary (F. K.).—A conservatory would be about the worst place possible in which to keep a bird at this season of the year unless the greatest care was taken to well protect the cage from the full glare of the sun. The Canary sent was too decomposed on arrival to permit of a full examination. Its sudden death may, however, be safely attributed to heat apoplexy, otherwise sunstroke, caused by the direct action of the solar heat. An attack of this kind does not always cause immediate death, but the patient will almost certainly remain in a paralysed condition for the rest of its life. Where there is disease of the liver or fatty degeneration of the heart heat apoplexy is pretty sure to prove fatal.—S. S. G.

POULTRY.

Hens with scaly legs (Inquirer).—Your hen had suffered from scaly legs, a disease which may be due either to a deficiency in the secretion of oily products or to parasitic influence, the latter being prevalent in confined runs or wherever space is somewhat limited. Langshans and their crosses are very subject to this complaint. The best treatment is to thoroughly bathe the legs with warm water, and, when dry, rub well with neat's-foot oil, afterwards applying a little vaseline. In severe cases a mixture of turpentine and paraffin will be found useful, the mixture being applied with a hard brush after the legs have been thoroughly washed with soap and water. It would be well to dress any birds that show symptoms of this complaint, and also to thoroughly cleanse and limewash roosting places used by the ailing birds. Zinc ointment and vaseline in equal parts are also serviceable in scaly legs. When the trouble arises from parasitic influence, sulphur ointment proves very beneficial.—S. S. G.

4TH EDITION.

NOW READY.

FARM & HOME YEAR-BOOK

A HANDBOOK FOR THE FARMER.

IF YOU WANT TO KNOW—

How to Manage your Stock

Tell the Age of Stock,
Treat their Diseases,
Value and Mix Manures,
Read an Analysis,
Test your Milk,
Manage Pastures,
Select Pasture Grasses,
Recognise Poisonous and Injurious Plants,
Make Various Kinds of Cheeses,
Identify Injurious and Useful Insects,

How to Graft Fruit Trees,

Measure Land,
Measure Stacks and Dung Heaps,
Get Compensation for Improvements;

All about Forms of Claim,
Scales of Compensation,
Ground Game Rights,
Income Tax Charges,
Employers' Liability,
Notices to Quit—

—BUY FARM AND HOME YEAR-BOOK.

Simple Farm and Home Cookery. Humours of the Country.

ALL THESE AND MANY MORE SUBJECTS DEALT WITH CLEARLY AND FULLY.

FRUIT.

GRAPES SHANKING.

It is found that Grapes never show signs of shanking until after the berries have stoned, and then when subject to this disease all appears satisfactory until colouring indicates a change from the acid to the saccharine state. When this dreaded stage is reached the affected eye is over on the alert for a few tiny black spots round the shank, a thin limpness of the stalk, and a stationary condition of the berries, both as regards size and colour. These berries never recover, but shrink rapidly to the shrivelled vinegar condition, whilst the remainder of the bunch, and other bunches in its entirety on the same Vine, will attain to the greatest perfection. Some varieties, notably the old Frontignan, are more subject than others to shanking, and, what at first appears strange, Vines started in midwinter never produce a shanked berry, whilst similar varieties in borders exactly alike, but started in the spring, are badly affected by the disease. The normal treatment in each case being all that the most fastidious grower can wish, the cause of the mischief, it is quite evident, lies principally, but not entirely, in the mismanagement of the roots. I use this term in a qualified form, I believe it is quite possible, where the roots are the run of the best border ever made, not to produce shanking, but to ruin the crop by withholding water, by overloading, or by destroying the best foliage when the Vines are in full growth. The conditions, however, under which shanking is most generally met with are

HEAVY CROPPING—that is, allowing the Vines to carry a weight of fruit altogether out of proportion to the spread of leaves, whilst the roots, white and fleshy like those of the Eucalypt, are feeding in fat borders—it may not be too damp, but most certainly too wet and cold. If Vines thus situated were started on New Year's Day, moderately forced and slightly cropped, it is more than probable the berries would not shank to any serious extent, perhaps not at all; but allow them to break naturally, give them plenty of rich liquid throughout the summer, keep their quill-like roots growing well into the autumn, and although the foliage may be dense, green, and plentiful, some berries in every bunch will shank. This shanking is easily accounted for in the following way: The leaves, as autumn comes on, cease to act, and in due course fall, but the roots started late die back, as they are far from ripe. The Vines, nevertheless, contain a certain quantity of stored-up sap, which keeps them through the early stages in the following spring; but so soon as this is exhausted by the first flush and setting of the fruit a check follows, as they have no feeders to maintain the supply, the few they made in the preceding year being paralysed, or dead. Now when a plant through any cause loses its roots, all gardeners know that it cannot renew them without the aid of leaves; consequently the formation of these has scarcely begun when the berries are passing the

STONING PROCESS; and although, as I have just stated, the disease does not then develop, it is owing to the pinch at this most trying of all stages that the foundation of shanking is laid. The same Vines, on the other hand, started in January have the whole summer in which to ripen their roots. These keep fresh and sound, and by the time the stored-up sap is exhausted, they are again not only in full work, but capable of replenishing the cells before the Vines feel the check. When Grapes shank, the owner should first of all ascertain that they are not over-cropped, that the foliage is clean, healthy, and plentiful, that the roots are liberally supplied with water, and the house properly managed. Finding these points satisfactory, he must seek the prime cause of this evil in the borders, and although possibly only recently lifted, his only and never-failing remedy will be found in lifting and relaying again. I will not go into details, as the preparation of compost and the formation of Vine borders are thoroughly understood, but this much I may say, the compost should be poor rather than too rich; bones should be used in preference to animal manure, and the drainage should be good. The roots formed in a well-drained porous border of this kind will be small, numerous, bright as gold, hard and woody, and so active that they will permeate the whole mass. These hungry mouths, capable of supplying any amount of wholesome food, it is hardly necessary to say, will ripen before the cold autumn rains set in, and in this condition they will be well up to, if not actually in advance of, their important work in the following spring.

MELONS AND CUCUMBERS IN COLD FRAMES AND PITS.

THERE is no way in which cold frames and pits that have been used for bedding plants can be employed better than by using them to grow Melons and Cucumbers in. For these the frames require but little preparation, although the plants get a gentle heat for the roots which will help them considerably by giving a start. A ridge of soil should be laid along through the middle. If the intention is to grow Cucumbers, fresh, light, fibrous soil is the best, and any gatherings from the roadside, with grassy loam, chopped up and roughly mixed, will just suit the plants. The same will also do for Melons, but they require a firmer or closer root medium, and anything used for them should therefore be trodden down, or the Melons will be found to run too much to leaf. For an ordinary-sized light two plants are quite sufficient, the one to be trained towards the front and the other behind. To fill up those parts, all that has to be done is to train two leading shoots from each plant, by running them in lines towards the four corners, and as soon as they get within a foot of the sides the ends should be stopped. This **PINCHING OUT OF THE POINTS** will force them to break, and the laterals they send out will all, or nearly all, show fruit. As soon as they do this they should be stopped at one, or at most two joints beyond, and very quickly used

the flowers on the young fruit will open. The thing then is to ensure a good set, and to bring this about it is necessary to fertilise the blooms, as no dependence can be placed on the pollen being carried by insects. It is very important that the fertilising or setting be all done in one day, otherwise one or two fruits will start and take the lead, and others will not move at all, as the strength of the plants seems absorbed in those that pull on them first. Frames and pits that are started without bottom-heat should be kept shut for a few days after the soil is put in, so as to get it warmed before the plants are turned out, as they may get a chill at the roots, and when turned out it is a good plan to keep them nearly close and shaded, as then the heat from the sun will assist the plants to root. As soon as the start is fairly made then more air must be given during the forenoon, and

SHADING, so far as the Melons are concerned, abandoned, as they delight in sunshine, but to aid them in their growth and swelling the fruit they should be closed about 3 o'clock, and kept so till about 7 or so next morning, when it will be necessary to tilt the lights slightly to prevent the leaves from scalding. Before shutting up the frames the plants should either be syringed or sprinkled with tepid water, and never at any time allowed to become dry at the roots, as when that happens a severe check is given and red-spider follows. Melons are rather subject to this insect, but by maintaining plenty of atmospheric moisture in the way referred to it may be prevented or held in check, and the plants kept healthy and strong.

NOTES AND REPLIES.

Figs failing.—I have a large Fig-tree—Brown Turkey—on a south wall, covering 18 feet by 24 feet. Last year there were several hundred ripe Figs. In the autumn I tied in the branches, but did not prune for fear of causing long, soft shoots. Now there is a fair quantity of fruit on the outside branches, but the centre is crowded with unfruitful and weak but short shoots.—F. FOWLER WARD.

[The remedy is in your own hands. Cut out all the weak wood and allow the sun and air to get at the remaining branches, so as to well ripen the wood. The reason of the failure to fruit is that the wood in the centre of the tree is far too thick, and is in consequence soft and unripe.]

Summer pruning.—Can your correspondent in your paper of July 19th add to his valuable information answers to following? 1. Wall fruit: In addition to pinching of shoots, would it be more advantageous to cut back the growth intended for extension of tree during the summer or autumn rather than leave it to be done in the early spring? If so, when should this be done, and how much should be taken off? A third part is, I believe, usually laid down as the length to suppress. 2. Pyramids and bush-trees: The same as regards Apples, Pears, Cherries, and Plums? 3. Currants: Would it be more advantageous for next season's fruiting to cut back to six leaves all the young growth of Red, White, and Black Currants during summer, rather than hard prune Red and White after fruiting is over, and thin out only some of the old wood of Black Currants, which is generally laid down as the method for pruning this fruit? In a season like the present, where the growth of young wood has been so great and rapid, it is rather difficult, except by employing a good deal of fairly skilled labour, to keep all in touch with one's trees and bushes before the young growth has reached almost too great a length—certainly too great to allow of pinching with finger and thumb.—Close.

[The special object in view, when summer shoots are pinched, is done whilst tender, or cut back it done later, is to cause the back wood to be the main branch—to

plump up and gradually to change from wood-buds into fruit-buds. That reason does not apply to leading or extension shoots, which it is the rule to allow to extend fully, especially as their free growth helps to counteract any check to a tree that may result from the pinching or cutting back of all other shoots. As a rule, it is best not to pinch summer shoots too soon, but rather to shorten them to about four or five leaves early in August, shortening the leader shoots in the winter. Precisely the same rule applies to pyramid and bush-trees, each main branch being spurred in this way so as to form a sort of cordon with a free leader, which may be cut back more or less hard in the winter. In pruning Red or White Currants, it is best to cut back one half the shoots when well grown to about five or six leaves, and the other shoots to double that length. That leaves on the bushes ample leaf area, as it is the duty of the leafage to mature wood and to form fruit-buds for the following year. In the winter all these summer shoots may be cut back quite hard, say to a couple of leaf-buds, as the primary object in pruning is to cause clusters of fruit-buds to form close to the main stems. As a rule, Red Currants are not pruned one half so hard as they should be.

it is not the soil alone which is at fault when the same variety will succeed and fail when procured from different sources. There cannot be any question that far too many plants are perpetuated from a debilitated stock, and this is why failures are so frequent with special varieties for forcing. What is wanted is a good stock to start with, raising the batch for forcing from yearling plants grown for the purpose if possible. A variety which requires extra care is the good old Keen's Seedling, than which when well grown there is not a better second early in cultivation. The first care is to get a good stock, and then to look well after it by layering the stock annually.—A.

PLANTS AND FLOWERS.

FERNS.

STAG'S-HORN FERNS (*PLATYCUERIUM*).

A very remarkable genus of epiphytal Ferns, differing from all other known kinds in the manner of their growth and the extraordinary configuration of their fronds. They are large stemless plants, with fronds of two sorts.

P. ALCICORNE.—This species, on account of its small barren fronds and the quick manner in which it throws out young plants from its roots, forms a fine object. It will thrive either in the stove or greenhouse. It comes from the East Indies and Australia, and there are several distinct forms of this.

P. GRANDE, also from the East Indies and Australia, should be grown on a large block. The fertile fronds reach a length of from 1 foot to 3 feet, and it succeeds best in the stove.

P. WALLICHI, from the Malayan Peninsula, somewhat resembles *P. grande*, but the fertile fronds are shorter and broader.

P. WILLINGII is another very pretty Stag's-horn Fern, seedlings of this soon developing fertile fronds, which are narrow at the base, terminating in deeply-cut segments of a pale glaucous green and of a drooping habit.

GROWING ADIANTUM CUNEATUM.

It is not everyone who has favourable houses for the growth of this popular old Fern so as to provide a supply of cut fronds of enduring character. What is wanted is a light, well-ventilated house with good control over atmospheric moisture, the plants being as near the

Platycerium zethiopicum (syn. *P. stemmaria*). From a photograph sent by Mr. Geo. E. Low, Dublin.

Black Currants must not be so pruned, as these bear from the leaf-buds of the preceding year's shoots. Therefore, except in the case of quite young bushes that have to be formed, the summer shoots of one year should be left to fruit the following year. Still, the bushes need thinning, and to that end old wood or branches should be cut hard out. From beneath the cut strong shoots or suckers generally break, and those become fruitful. Probably many trees will benefit by root pruning next winter where they have made such a strong growth of wood as yours have.]

Strawberries—change of stock.—Most cultivators will bear me out when I state that at some time or other, when visiting other gardens, varieties are seen doing remarkably well, although the treatment they are receiving differs but very little, if any, from that given the same variety in other places. Of course, good culture is answerable for a deal of the success, but not to such an extent as to make any difference noticeable. A cultivator, in selecting his varieties for forcing, may be very careful in choosing and layering the earliest runners obtainable, also growing them on in a rational manner, and yet he may not succeed in securing high quality fruit, and this plentifully. Soil no doubt has great influence on the well-doing or otherwise of many varieties of Strawberries, but it is quite evident, that

Those first produced are broad, entire, and spread almost horizontally, forming a shield. These fronds are barren. As the plants grow, the fertile fronds develop from the centre of the shield, and are quite different in form from the barren fronds, from which they stand out in all directions, sometimes to the distance of 2 feet or 3 feet, presenting very much the appearance of a number of stag's antlers grouped together. All the species require a stove temperature, with the exception of *P. alcicornis*, which may be grown in a greenhouse. They do best fastened on to blocks of wood, so that they can be hung up in the house, according to convenience. When fastened on these blocks with copper wire, some Sphagnum and fibrous peat should be packed behind the barren fronds, and the plant and block immersed in water until the soil is thoroughly saturated. After this, the only cure needed is to see that the atmosphere is kept moist and sufficient water given to maintain the soil in a nice moist condition.

The following are the best known kinds:—

P. AETHIOPICUM (syn. *P. stemmaria*), which we figure to-day, is a fine stove species from Western Africa. The barren fronds are permanent, but differ from those of the other kinds in that they die annually and take on a chestnut-brown colour, being, however, hidden by the young ones produced in the spring.

glass as possible and in no sense overcrowded, otherwise the lower fronds, and others where the growth is dense, will either turn yellow or damp off. Damping off spreads rapidly in a humid and close atmosphere with possibly no fire-heat. This latter accessory cannot be considered essential by any means, being all the better for the plants if dispensed with entirely, provided other means are equal to the case. By this I mean a proper system of ventilation both by night and day, with no over-shadowing from other plants. At all times should more or less air be left on; by this means there should be no signs of moisture upon the plants in the form of dew in the morning. The greater part of the watering should be done early in the day, with no late evening damping down. A good lasting growth will in this way be obtained, the fronds of a pale green, with small pinnae as compared with those of other plants grown in more moisture, more warmth, and more shading. What may be termed the cool treatment is not nearly enough seen in practice. Many growers do not sufficiently realise the fact that this Fern is but little removed from a greenhouse plant as to its actual needs. On the other hand, it is rarely possible to grow it well in houses with heat and moisture, but in order to do this in the best possible manner two or three points have to be considered. Firstly, the position should be

one with a large amount of light; secondly, the plants in warmth should be of the two in smaller pots proportionately than those in the cool, and, thirdly, the watering ought not to be excessive, nor overhead syringing be permitted. In this way it is quite possible to so manage the plants as to make them in every way valuable. In no case should over-potting be permitted. To fancy that fresh potting is needful every year is altogether a fallacy. It may be urged by some that they cut such a quantity of fronds, and therefore the plants need to be repotted; whereas, in fact, quite the opposite is the case. Take two plants, for instance, in health and of equal conditions in all respects; pot the one, giving an average shift and treat in the usual manner, leaving the other not potted at all, but assist it, if needful, with manure-water and clear water also in plenty. When the growth is fit for picking treat both plants alike, cutting them hard if needful, and after this act which plant of the two will afterwards recover itself and be presentable in a given space of time. The plant that has been re-potted will stand the greater risk of losing its roots, or, at any rate, of having them weakened considerably.

GROWING IN PITS.—When the house room is not sufficient to accommodate the plants satisfactorily, and there are pits or frames at disposal, let these be turned to account for their occupation, standing the plants on a bed of ashes, the depth being sufficient to allow of the plants standing upon a 4-inch pot inverted, this being much better than close upon the ashes. Top and bottom air is left on all night to prevent any damp, and a very light shading is laid on the glass during bright sunshine, as the plants are close up to it. Here these plants may remain until the middle of September at the least, and they are better off than if shaded in houses by other plants.

If only a more rational mode of culture were adopted with this popular Fern we should not hear so many complaints of the fronds not standing well when cut. What is wanted is hard fronds, to use a popular phrase, and these can only be had by what may also be termed a hard course of treatment. A young stock of plants should also be coming on to supply the place of those becoming exhausted.

ROOM AND WINDOW.

CACTI FOR WINDOW CULTURE.

Many of the Cactuses are of the easiest culture in windows, and few plants give so ample a return for slight trouble. The seedlings which have been raised in recent years are far in advance of the old type, hybridisation having improved them greatly, and those who are interested in window gardening can scarcely do better than procure a few specimens or a collection of these lovely flowers. Their cultivation is simple. Plenty of water (they love to stand in a saucer) during their flowering season and a sunny window are all they need; the supply of water being continued through the summer (when they make their growth), and gradually diminished during October, giving scarcely any water from the beginning of November until the end of February. During this dormant period the plants should be moved away from the window, and they can be kept safely in any place where the temperature does not fall to freezing point, only very occasional

watering being desirable, just enough to prevent the fleshy leaves from becoming flaccid and wrinkled. When March arrives they should be replaced in the window, as near the glass as possible, and supplied with saucers, these being filled every morning with warm, but not too hot, water. At the same time the dust of the winter may be removed with a paint-brush and clean tepid water, and the hard upper soil changed, without disturbing the surface roots, for a little fresh compost. In a short time flower-buds will appear at the edges of the leaves, and with a good supply of water (to which a little clear soot-water may be added) will swell rapidly, until the plant becomes a mass of bloom. Each of these should be removed directly it fades, to avoid exhausting the plant, and the opening buds should be turned to the sunshine, or they sometimes drop off. These cacti may be propagated very easily by cuttings; a leaf, or even a part of a leaf, cleanly cut from the old plant, can be laid aside to dry for a day or two in the shade, and then inserted firmly in a small

blossoms of the annual *Gypsophila elegans* and long sprays of elegant Grass plumes gave a charming and pleasing finish to the whole. The fourth exhibit, which was exclusively confined to garden Roses, was pretty, but being indifferently arranged the general effect was rather poor. When the verdict of the judges was made known, to the surprise of many the first and second prizes went to the two exhibits first mentioned above. The judges in coming to their decision absolutely ignored the essentials in regard to a proper artistic production. The colours of the Sweet Peas in these two sets of stands were of a very mixed kind, embracing bronzy-chocolate, purple, blue, crimson, and other colours of a softer and more pleasing hue, all ingloriously muddled together. The *Gypsophila* helped to relieve the incongruous arrangement to some extent. The general public, many of whom know very little about these things, and who visit these exhibitions in the hope of learning something, leave the show with an altogether erroneous idea of what is

Cactus Jenkinsoni grown in a window. From a photograph sent by Mr. J. Sofey, Netherleigh, Tibberton Road, Great Malvern.

pot of sandy soil (without manure), well drained, when it will soon strike root, and can be removed to a little larger pot in October. Do not repot Cactuses often, and use rather light soil.

JUDGING FLORAL DECORATIONS.

With the remarks on "Floral Decorations," in the issue of GARDENING ILLUSTRATED for June 14th last, I, with many others, am in full accord. There is no more frequent example of bad judging than in the exhibits of floral decorations, and in local shows these mistakes are often met with. Colour and its proper associations are, to my way of thinking, of primary importance, and unless a due regard be paid to the use of colours, it is impossible to achieve those artistic results which all true floral artists strive after. I have in my mind at the time of writing an instance of exceedingly bad judging. In the case to which I allude a competition for a dinner-table decoration was provided and there were four competitors. Two of the exhibits were very similar in their appearance, and were confined to Sweet Peas, with *Gypsophila elegans* and Asparagus, etc., as adjuncts. A third set was also confined to Sweet Peas, in various shades of pink, and the minute

the proper thing to do, being entirely misled by bad judgment. These facts prove how real is the need for persons to judge who have a full and proper knowledge of that which goes to make a floral decoration in the truest sense. "S. W. F." is quite right when he says that the number of those who can rightly judge is extremely limited, and there is a great deal in what he suggests, as to affixing a plainly written card giving the reason for awarding or withholding a prize. No person should be asked to adjudicate upon any exhibit of the kind referred to unless he can give his reasons for making the award. D. B. CRANE.

Keeping cut blossoms.—Every year at this period, when there are flowers in abundance, one is not with the inquiry as to the best way to keep cut flowers from falling, both to the private grower and exhibitor alike the matter is an important one, and though many of the methods employed are old, yet they are worth recalling now that a need for them presents itself. It depends very much when blossoms are cut and how they have been grown as to whether they will last long. An old exhibitor would not think of cutting any of his blooms that had been over-exposed to sunshine, but would select the early morning when the dew was yet upon them, placing them in jars

of water in a darkened room until required. For flowers for the house, one can adopt a similar course, gathering them either at night or before the sun's power has become felt too much, and so have them in their freshest state before they have time to go limp. The vases or bowls of water in which the blossoms are placed should contain a little charcoal, which will help to keep it sweet, and wet sand over the surface of which green Moss is scattered, often used by exhibitors, will be found convenient. I know someone who always has a little salt in the water to ensure the flowers keeping. The old advice to cut off a portion of the stems each day cannot be followed with all flowers, as in the operation itself failure often ensues. I believe it depends more us to when the blooms are cut whether they will last long, and this is undoubtedly best when three parts expanded and gathered, as stated, early in the morning. Do as one may, the weather is a great factor in the matter, and must be taken into account, for, after all, our most promising blooms are but fleeting, and are not proof against tropical heat. Often when we think we may keep them and try our best to do so we are disappointed. —LEAVINIST.

INDOOR PLANTS.

HERBACEOUS CALCEOLARIAS.

Time was when gardeners and others cultivated a named collection of these beautiful greenhouse plants, but nowadays few people think of this mode of culture, seedling plants giving far and away the best results. July is a capital time for sowing the seed, and, in order to secure the best results, the finest strains only of the seed should be procured. Take a shallow box or a seed-pan, well drain with crocks, and over these put a layer of nice, sweet, turfy loam, fill up with a compost of sifted loam and silver-sand to within an inch of the top, giving the pan a sharp tap on the bench to settle the soil. Immediately after, water through a fine rose, and sow the seed on the surface. The seed, being so minute, no covering of soil is required. A good plan to follow in sowing these or any small seeds of a similar character is to mix the contents of the packet with a pinch or two of dry silver-sand, and sow as usual. This ensures the seed being scattered more evenly than it would otherwise be. The best place for the pan or box after sowing is a cold-frame from which the sun is excluded. This should also be darkened until the seeds germinate, when it must be removed to prevent the young plants from becoming drawn. When the plants are strong enough or have made two pairs of leaves (other than the seed leaves), they may be pricked off into other pans or boxes, made up as before. Give them a gentle watering overhead, and keep close for a few days until they recover from the check, when air may be admitted on every fine day. By the end of September they will be requiring a shift, and pots 3½ inches in diameter may be used for same, the soil being fairly rough and fibrous, and mixed with a good dash of sharp sand and a little leaf-mould. After potting, they are better in the greenhouse on a nice airy shelf, and free from artificial heat.

Some gardeners do not approve of pinching these plants, but having tried both ways, I am of opinion that pinching the plants when 6 inches high induces growth of an even and strong constitution. The stronger a plant is and the healthier it is the preventer to a great extent the plague of green-fly or aphid which is wont to worry it in spring. As the 3½-inch pots get full of roots shift into the 5-inch size, and therefrom to the 7-inch or 8-inch pots, in which, if all the shoots are carefully tied out, magnificent specimens, well repaying any extra trouble expended, can be grown. In staking, many a good plant is often spoiled owing to the stakes being too thick and of white wood. For Calceolarias especially the thin twigs which are cut from the Willow-tree are indispensable for staking. When the buds appear weak liquid-manure should be given every alternate week, gradually discontinuing same as the flowers open, and shading from hot sun.

D. McIVER.

Bridge of Weir, N.B.

PLUMBAGO CAPENSIS.

This easily cultivated plant should not need any recommendation: its rapid growth and lovely pale blue trusses of flower should alone be sufficient in this respect. Yet it is not seen nearly so often as one could wish. In growing this, plenty of sunshine and not too much atmospheric moisture are essential points. If at all shaded the growth is inclined to be weakly, with less disposition to flower, and if grown in too moist an atmosphere the growth will be far in excess of all needed requirements. If the plant be grown in the open border of a light cool house, the soil should not be too rich or of a great depth: it should consist for the greater part of light loam and road-grit or sand, and this should be made as firm as possible. In pots the same soil will suit well with a little peat added thereto. The sunniest spot, even in a light house, should be chosen for it, and as far as is practicable freedom of growth should be allowed, close pruning being

Cape Leadwort (Plumbago capensis).

the rule during the resting period, and that well in advance of the starting into activity again. To tie in the shoots as they grow for the sake of trimness is utterly wrong and out of all character; only just sufficient of this kind of work should be allowed to keep the shoots from breaking down with their own weight. If it is seen that the growth is too free, of which there is more danger than the reverse, then less water should be given for a time; this will have the desired effect of producing flower-trusses plentifully in due course. For the flower garden Plumbago capensis is admirably suited. If grown as standards in 10-inch or 12-inch pots and plunged the effect is excellent, sufficient room being allowed for an appropriate undergrowth. Smaller plants can be planted en masse with good effect, and taller ones of long, rambling growth will be quite at home when trained against walls or verandahs in sunny positions. In a cut state the flowers quickly fade, and are in nearly every case disappointing.

NOTES AND REPLIES.

Tuberous Begonias.—These are wonderfully useful in pots as well as in flower beds, having undoubtedly largely surpassed or taken the place of many older things. The old tubers now growing freely should not be hurried, unless carelessness is an object. These will now be quite safe in a cool pit or frame if the houses are so crowded as not to allow of sufficient room for them. They enjoy a moist, cool bottom to stand upon with gentle dampings overhead in the after part of the day when it has been warm and sunny. The lights even may be left off in the daytime if in a fairly sheltered place; this is almost better than having them on without a slight shading. Where any tubers have progressed more favourably than usual, giving promise of making extra good plants, another shift may be allowed them into pots one size larger. This will be found far better than staving them, so to speak, the flowering period being thereby lengthened. Good loam and leaf-soil in about equal parts will suit them well, but of the soil be not altogether first-rate then add a few handfuls of a well-tried and reliable artificial manure. Seedling plants of this year will be all the better if still kept a trifle warmer, any house or pit wherein a fair amount of artificial heat is still being used being suitable. Where late seedlings are not yet potted off no time should be lost if they are fit.

Plants for conservatory.—I have a conservatory opening from the drawing-room, facing south, north and west, heated by hot water in the winter. I am anxious to keep this filled with flowers from August to January. Would you advise me what to sow? Is it possible to cultivate Stocks and Peas? My gardener says it is too late to sow Primulas and Cinerarias, though he has a forcing-house. I planted some Campanulas last April, and they are just big enough to pot off. Will they flower this year indoors? If I sow Lobelias will they flower in time?—V. O. B.

[There are many things well suited for a conservatory during the times stated, but it is late to be starting now for a beginning. Some of the plants that may be grown with ease, and that could be accommodated in pits or in the open air in winter, are Hydrangea Hortensis and Hydrangea paniculata grandiflora. These kinds are showy and valuable. To these may be added quite a host of showy Lilies, such as auratum, tigrinum, speciosum, in at least three kinds, longiflorum in two kinds, all of which may be grown out-of-doors in pits plunged in ashes till required. Of other plants that but little trouble in winter to preserve roots are Achimenes and Tuberous Begonias. These latter are especially valuable in pits, a cool conservatory, and only require starting into growth quite naturally to suit your case. Such trailing Campanulas as C. isophylla alba, C. i. Mayii, and C. fragilis are also valuable. It is, as the gardener observes, too late for sowing Primula and other such things, yet you may purchase seedlings of all these at a small cost. If the Campanulas you refer to are the Chimney Campanula (C. pyramidalis), they will not be large enough to flower this year, and, indeed, will only arrive at a good flowering in July, 1903, by continued good cultivation in the interval. As a rule, these things require fully sixteen months to make blooming examples, and by this method it will be easy to maintain a flowering each year. Sown in early spring, the seedling plants should receive every encouragement, and be in 6-inch pots by the early autumn. Then winter in cold-frame or house, and in February or March give a final shift to 9-inch or 10-inch pots, according to size of plant individually. The Canterbury Bells may also be grown in pots for flowering indoors. For later work, summer-flowering Chrysanthemums in batches and a few good late kinds would keep up a display to the end of the year. Bulbs of all kinds, Daffodils, Tulips, Freesias, Hyacinths, Lily of the Valley, etc., should be secured in early autumn for giving winter supplies of bloom. The Lobelia may flower a little if sown now, but you would not obtain a tithe of its flowering value before the end of the season. Such things require to be sown in February.]

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS," or "THE ENGLISH FLOWER GARDEN," to the possessor of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus:—

OUTDOOR PLANTS.

ANNUALS IN THE GARDEN.

ALTHOUGH too much reliance should not be placed on annuals for the adornment of the garden, their usefulness for a variety of purposes should not be underestimated. They may be planted amongst bulbs, and then in the autumn, when the foliage of the bulbs has withered and disappeared, they will cover the earth, which would otherwise be bare, with bright colour. They are also useful for growing around subjects like *Dicentra spectabilis* and the Oriental Poppy, both of which wither and become unsightly before the commencement of autumn, at a time when many annuals are growing strongly. Some, like the deep blue *Phacelia campanularia*, are seen to advantage when grown in pockets in the rock garden among grey-leaved *Sedums*, and *Saxifragas* and *Verbenas* do well pegged down in a border where *Crocuses* are planted. A method beloved of the jobbing gardener is to "tidy up" the borders by cutting off the foliage of the bulbs after their flowers have faded. This has the most disastrous effects, for the bulb of the ensuing year is built up by the sustenance drawn down from the leaves, and if these are cut off while still green the supply is suddenly stopped, with the result that the bulb can make no further increase in size. Under such

by the plants later on, when compared with the stunted stature of the puny weaklings in the unthinned bed. There is no more beautiful flower than the single white Opium Poppy, but, unless the seedlings are a foot or 18 inches apart, they will not attain their rightful dimensions. Asters are particularly valuable autumn-blooming annuals. Great so-called improvement has been effected in these flowers since the single *Aster sinensis* was introduced some 170 years ago, and we now have numerous double forms known as Paony, Comet, Quilled, Crown, Pyramidal, Chrysanthemum-flowered, etc. The single Aster from which these were originally derived was lost to cultivation, and was only re-introduced a few years ago. This plant, when given good soil and plenty of room, forms a branching bush 3 feet or more in height and as much through, and bears great many yellow-centred flowers, the largest of which are fully 5 inches in diameter. When this plant is compared with the double Asters of to-day one feels that the alteration effected in a century and a half has been a retrograde movement and not an advance. However, all nurserymen now sell seeds of *Aster sinensis*, and white and rose-coloured forms can also be obtained.

Many other annuals besides those mentioned are of infinite use in the garden as long as they do not displace herbageous plants. Of these may be mentioned *Galettias*, *Coreopsis*, annual

looking north, protected from wind by a Beech forest on south side only, and the soil tenacious, yellow clay; most unfavourable conditions for producing anything very early, yet every year my autumn-sown Sweet Peas are glorious, bloom early, grow very tall, and flower for months. The other invariable success in autumn sowing is Poppies—Shirley and red double Coquelicot. I was less successful with *Galettias*, annual *Coreopsis*, *Eucharidium*, and *Antirrhinum*, although once obtained they sow themselves freely. Some double rose-flowered *Balsams* sowed themselves last summer and came up satisfactorily quite late in the spring. They astonished me, as they are not noted for hardiness. *Papaver bracteatum* has become almost a weed here. It is so happy in our clay soil, also *Lupinus polyphyllus*, which has been in June the pride of the garden. May I send a longer article dealing with plants which succeed or go wrong in our yellow clay? My experiments may help other readers.

[Many thanks; shall be glad to have your experience.—Ed.]

TUFTED PANSIES IN JULY.

THE cool and moist weather of the first three weeks of June suited those plants, and rarely have they flowered so well or the individual blossoms been better. The most astonishing fact is that the plants which were put out in March and April grow away freely, and have since that time been all that one could desire. No doubt the constant stirring of the soil between the plants has contributed largely to their present satisfactory condition. From time to time, too, I pick off all the spent blossoms and seed-pods, thus giving the plants a much needed rest, and this, too, without seriously interfering with the brightness of their display. Within a week from the time the blooms, etc., were removed, the plants were again flowering freely. Insect pests have not caused any trouble, and this is something to be thankful for. However, when the plants are attacked by red-spider, green-fly, etc., they may easily be eradicated by a timely application of soft-soap solution. This solution is made by dissolving 2 ounces of soft-soap in a gallon of clear water, and is squeezed into the points of the shoots of the affected plants by a sponge or piece of flannel. In hot weather this should be done in the evening and syringed off in the morning before the sun gains much power. No better time could be selected for applying this remedy than when the plants have had their flowers and spent blossoms picked off. In hot weather, too, copious supplies of water should be given, these being followed with liquid-manure water. In very hot and dry situations it is a good plan to mulch between the plants with some rotten manure, this keeping the roots cool and thereby encouraging growth. Peat-Moss-litter has been used here, and with much success. It is well, however, to turn the heap over pretty often before using this material, otherwise the ammonia, with which this substance is heavily charged, may burn or blister the foliage. The larger pieces of peat-Moss-litter should also be broken up. Particularly pleasing now are: *Seagull*, a rayless white, with a very neat yellow eye; *Florizee*, lavender, with a perfect habit; *Mrs. E. A. Cade*, bright yellow and rayless; *Miss Jessie Cotter*, a rayless flower in varying shades of yellow; *Miss Gertrude Waterer*, bluish-white, wondrously free, perfect habit; and *Elaine*, large pure white, with yellow centre. King of the Blues, the best of the blues, of medium size, was raised by the late Dr. Stuart, and another of the same raiser's is *Pensee d'Or*, a very rich and deep rayless yellow, an ideal bedding sort. A bright yellow, specially free, and beautiful for beds and borders, is *Clondyke*.

Original from Sweet Peas, early sowing.—Your correspondent, W. L. B. (see page 263),

A bed of China Asters.

circumstances it is impossible to expect bulbs to flower well. It must be admitted that, if bulbs are grown in the borders there is a time when their appearance leaves much to be desired; but if annuals are planted amongst them as early as they can with safety be put out in the spring they will soon grow away and do much to hide the withering leaves of such bulbs as *Daffodils*.

As cut flowers annuals are invaluable, and in the reserve garden they should be largely sown. In sowing, the greatest care should be taken to sow thinly. The growth of a self-sown seedling which rises alone in a bed evidences to what dimensions a plant will attain when it has not to strive for existence with others of its kind. A blue Cornflower seedling that came up by chance in a bed measured, when its growth was completed, 4 feet in height and 2 feet in diameter, and carried hundreds of flowers. It is far better to sow too thinly than too thickly; if fact, it is almost impossible to sow too thinly. Thick, or even moderately thick, sowing entails laborious thinning of the seedlings if those left are to attain satisfactory growth. As a rule, in addition to sowing too thickly, seedlings are insufficiently thinned. *Mignonette*, *Gypsophila elegans*, and *Sweet Peas* should be thinned to 4 inches apart; 6 inches is better. *Shirley Poppies* should not be nearer together than 8 inches. The thinning to this extent of a bed, say, 18 feet square, of the latter flowers means a considerable amount of labour; but this is well repaid by the vigorous and robust growth exhibited

Chrysanthemums, *Bartonia aurea*, *Suljiglossis*, *Stocks*, *Zinnias*, *Marigolds*, *Phlox Drummondii*, *Nemophila*, *Limnanthes Douglasii*, *Sweet Sultan*, *Lavatera trimestris*, *Sunflowers*, *Petunias*, *Cosmos bipinnatus*, *Antirrhinum*, *Linum grandiflorum*, *Schizanthus*, *Marguerite Carnations*, *Eschscholtzia*, and *Scabiosa*.

S. W. F.

AUTUMN-SOWN SWEET PEAS.

I SHOULD like to relate my very successful experiments with autumn-sown Sweet Peas. I sow them every 10th of September. They grow well at first, and seem to die down entirely with the first frost. Then in spring they come up again with great vigour, and bloom much earlier than those sown in spring in the open. This summer (when everything was backward on account of late, prolonged spring frosts) the autumn-sown Peas bloomed on the 20th June, and the spring-sown on July 4th. All varieties do not seem equally hardy. This year I put in *Invincible Carmine* and *Sadie Burpee*. The former came up much more thickly after winter. But *Sadie Burpee* had longer stalks; the length was 15 inches the first week—not a few exceptional ones, but they were all that length—and three flowers to every stalk. *Invincible Carmine* had only 12-inch stalks. The method of culture is simple enough. They are sown in good vegetable garden soil, each seed in a small hole about 18 inches deep. They are neither covered nor mulched, and my garden is a slope

has had a quite different experience to mine, as my early sowings gave stronger growth and bloom a fortnight earlier than the late-sown ones. I did not use any pots, but sowed the first lot the first week in December, 1901, and the next lot in February, 1902, my object being plenty of bloom at a minimum cost of labour. I had abundance of bloom during what should have been Coronation week in June. My impression is that pots check the roots from going straight down to find moisture.—J. Groom, Gosport.

NOTES AND REPLIES.

Soldagdos.—I do not know why in some gardens valuable space is given up to Soldagdos. I grew them years ago, but rooted them up when it was found that some Rose-trees in close proximity to them were being swamped, owing to their abnormal growth and the fact that nothing else did well near them. They are very well as fill-gaps in shrubberies when one has nothing else, but from a small garden they are in my estimation better omitted.—W. F.

Dimorphotheca Eckloni.—This recently introduced plant is a welcome addition to the somewhat numerous so-called Marguerites. The flowers are from 2 inches to 3 inches across, pure white on the inside, and shaded with purple on the exterior surface, the disc being of a deep violet. The culture is similar to that for *Chrysanthemum frutescens*. The plant may be grown to a considerable size, but is apt to become somewhat leggy and straggling when old, and it is better, therefore, to raise a stock of young plants annually, and discard after the second year.—J. Ross, 1, Ravelin-road, Oxford.

Clematises Lady Caroline Nevill and Fairy Queen.—Belonging to the lanuginosa section there are some very beautiful Clematises well suited for planting out-of-doors, but differing from those of the Jackmani group in that they only require a moderate trimming of shoots every season, whereas Jackmani and all of that group benefit most if cut hard back every autumn. The varieties I wish to call attention to are Lady Caroline Nevill and Fairy Queen, the former blush with mauve bars, whilst the latter is pale flesh in colour with pink bars.—WOODRASTWICK.

Begonias out-of-doors.—During the past few weeks outdoor Begonias have bloomed exceedingly well. There is a growing disposition on the part of many who have window-boxes to plant the tuberous-rooted sorts, and some that I have noticed this season have been charming, being a blaze of colour, quite a relief to the combination of Calceolarias, Geraniums, and Lobelias one sees so frequently. Where one has to buy plants for bedding or windows, Tuberous Begonias should not be overlooked, as the tubers can be kept all the winter in a frost-proof place and started in a house-window the next year with a certainty of doing well.—W. F. D.

Day Lilies.—Valuable plants for shady and moist borders or for planting near to streams are the Day Lilies, but it is next to useless to grow them in dry, shallow soils and expect success. Where, however, they can have a cool root-run, they bloom freely, require scant attention, and are very acceptable when cut. The common yellow-flowered variety, *Hemerocallis flava*, is met with in many gardens, is fragrant, lasts a considerable time in bloom, and is readily propagated by dividing the roots, as, indeed, are the other sorts. *H. dumortieri* precedes *flava* in blooming, but is not so continuous with its flowers. All who have opportunities for planting these showy subjects by the waterside should do so, in company with Irises.—DERRY.

Alstroemerias.—A warm border where the soil is both light and rich is the place best suited for Alstroemerias. When growing in groups in the garden they are most effective, but are not always understood, as, for instance, though needing a warm border they must, whilst growth is proceeding, be supplied with moisture at the roots, otherwise the tubers ripen too quickly, and after they have done blooming the flower heads should at once be removed to prevent exhaustion, but leaving the stem intact so that ripening of the tubers shall not be interfered with. During winter also it is advisable to spread over the surface a good thick layer of manure. It is imperative that the place Alstroemerias are to occupy should be thoroughly prepared, and this consists in digging out the soil to a depth of 3 feet, laying in the bottom pieces of brick, over which leaf-soil or manure should be spread. In preparing the plants in autumn, arrangements

should be made to have them in pots, for if lifted from the soil it invariably follows that the roots are injured, being, as will be seen, deep rooting subjects. It is on this account that when once they have been planted no further disturbance should take place.—LEAHURST.

Increasing Sweet Williams.—I have a splendid bed of Sweet Williams. They were raised from seed, and this is the first year of flowering. Each plant has from six to ten dozen young shoots round the base of old plant. Would the young shoots grow as well from slips or cuttings as they would from layers? In either case I shall (soon as plants have done flowering) have to remove them, as I want the ground for other things. If you prefer young plants to the old stools, what would you do with latter—destroy them? I suppose they would be no use without the young plants, as each shoot is a flowering spike.—CHAS. CUBBY.

[As your present flowering Sweet Williams have thrown so many young side shoots, you can adopt two or three courses. If you must remove the plants, cut down the flower-stems so soon as over, then lift each plant carefully with a fork, and, having made a hole to receive it, replant a little deeper than before, filling in round with good soil, and putting some about the young shoots. These would carry very fine flower-heads next year. If you can do so, it will be best to let the plants stop until October. You can, of course, layer the best shoots as if they were Carnations, using some sharp sand in the soil. Those layers would make stronger plants than if cut off as cuttings. But if you prefer cuttings, set them into shallow boxes filled with sandy soil, place them in a cool-frame, keeping closed and shaded in sunshine. These should root well in six weeks. If you left a few shoots to each plant, they would be worth preserving. If you have a fine strain, why not save some seed from the plants?]

Tufted Pansy—value of a good tufted habit.—Seldom have the Tufted Pansies looked better than they do at the present time. All through the moist weather of early summer they were making free growth and flowering profusely, and now that the atmospheric conditions are hot and dry they still continue to reward us with the brightness of their display. A notable feature this season is the handsome appearance of two-year-old plants. The display at the time of writing is remarkable. I leave a certain number of plants undisturbed for two seasons or more, in order to test their hardiness and robustness. A noteworthy fact in this connection is the satisfactory state of plants possessing, what all admirers of the Pansy (Tufted or otherwise) desire—a creeping-like style of growth. Plants of this description keep the soil far moister than others having a less desirable habit of growth, and for this reason the plants blossom continuously, and continue in a healthy condition right throughout the season. All the members of the "Duchess" family, represented by Duchess of Fife, Goldfinch, White Duchess, Duchess of Teck, and Ardwell Gem, are in splendid form. Others worthy of mention are Seagull, a very chaste rayless white; Blanche, syn. White Empress, creamy-white; Elaine, pure white, with yellow centre; Florizel, lilac and lavender; and Mrs. E. A. Cade, bright yellow.—D. B. C.

Starworts.—We owe much of the beauty of our autumnal flowers to perennials, and in blossoms of long standing it is open to question whether for a late display there are many to excel Starworts. There is an attraction in these charming flowers, and where bunches of bloom are required for house decoration every gardener should make room for some of them. It has been said that they occupy a dual of space; but this does not apply to all varieties, some of them being of a dwarf habit, and, if they encroach more than they ought to do, it is because they are not divided often enough. But tall-growing plants are needed on back rows, as well as dwarf sorts on the front, and a careful selection will prove the usefulness of both. I give an abridged list of each, and, if open weather is selected, Starworts may be planted any time between November and March. Varieties growing 1 foot to 2 feet high: *Sibiricus*, mauve, late; *Acris*, lilac purple; *Novi-Belgii* Pleiad, rosy-purple; *ptarmicoides*, white. Two and a half feet to 3 feet: *Novi-Belgii* Ianthe, pale blue; *N.-B. Madonna*, white, large; *N.-B. T. Smith*, blue; *N.-B.*

lavigatus, rose; *Coombe Fishacre*, flesh. Three and a half feet to 5 feet: *Novi-Belgii* Top Sawyer, rosy-lilac; *N.-B. Flora*, lavender; *N.-B. Ella*, mauve; *N.-B. Janus*, white; *N.-B. Robt. Parker*, lavender, yellow centre; *N.-B. White Spray*, sprays of white, twisted petals; *N.-B. F. W. Burdige*, one of the best white sorts; *levis* Lady Trevelyan, white, changing to rose; *Novae-Angliae* *praeox*, crimson-purple; *N.-A. ruber*, rich crimson; *turbinellus*, large violet, tipped rose; and *multiflorus*, small white.—TOWNSMAN.

Lenten and Christmas Roses.—I will feel obliged by being informed what is the proper treatment for Christmas and Lenten Roses under the following circumstances: They were bought, some in February and some in April, and were at once potted in rich, moss, loamy soil, with plenty of vegetable matter, in 12-inch and 12-inch pots, and were placed in a cool, shady position under a not very thick hedge facing east. Two of them (out of twelve) have gradually lost their leaves, and no growth is visible; the rest, while retaining their leaves, have made no further fresh growth this year, and look sullen and indisposed. Will they recover before the winter, or should they have a change in any way?—W. H. S.

[The behaviour of the plants, and of the latter group in particular, is exactly that we would have expected from so late transplanting as April. This is much too late, and for the simple reason that the chief rooting is past for a time, and the plants have virtually been existing upon their own stored-up vitality. The Christmas Rose family (*Helleborus* spp.) is best replanted in August or September, as in this way all, or nearly all, the root system, then freshly growing, are preserved intact. It is quite possible, if you examine your plants by shaking them out of the soil, you will find but few root fibres, and these of the main root type. If, however, any large or main roots are in sight, you can do little good, and had better wait for results; yet without root and foliage there is small chance of obtaining flowers, as these are always in proportion. If you require these things for pots, we would advise obtaining fresh supplies not later than mid-September, and potting at once, plunging the pots to nearly their full depth in some uniformly cool and shady place. Those now in pots would do better if planted out in the garden, as recovery is very slow when confined in pots. We wish it your plants have not been plunged; hence it would be difficult to keep them in a satisfactory condition. The soil you mention should be suitable, but soil in plant cultivation only plays one part, though naturally an important one. In the Christmas Roses two sets of roots are produced each year by healthy plants—viz., the chief or main roots only in autumn, and the fibrous roots in spring, usually with the leaf growth. If from any cause the main roots are checked or broken, the annual growth of the leaves, that usually takes place in February or March, is much impaired, and a generally weak, debilitated condition ensues, that from these reasons does not recover for a season or two. With the Lenten *Helleborus* the case is different, as this section inclines more to a perpetual rooting, making large quantities of root fibres each spring. This section may be replanted so late as April in good ground, and with every attention in watering, etc. The very nature of these and their great rooting render it necessary that the most liberal treatment should be given, and, even so, we do not recommend them as good things for pots, still less so if the pots are continuously exposed to the great changes of atmosphere ever going on.]

Sweet Peas—some good sorts.—One of the most conspicuous sorts this season is Prince of Wales. The flowers are very large, of good form, and rose-pink in colour. The majority of the sprays have developed four blossoms. The newer Duke of Westminster is even more robust than the last-named, its rosy-purple colour and good form, apart from its freedom of flowering, giving it a very high place in the list. Too much cannot well be said in favour of *Prima Donna*, the soft pink colour being charming. Rarely, indeed, does the spray develop less than four blossoms. Of the dark sorts, Black Knight appears to be the best. It may be described as dark bronzy-chocolate. The flowers are large and of good substance, the plant robust and also free-flowering. Among the pale yellow or rich cream flowers it is difficult to find anything

prettier than Queen Victoria. The flowers are very large, and each spray has a fine length of footstalk. Lady Mary Currie still holds its own among the rich salmon coloured sorts. The deep mulberry-red of Salopian stamps it as first class in its colour, and the chasteness of Sadie Burpee has a value which none of the other whites possess.—D. B. C.

Pretty annuals.—Too many gardeners, and amateurs especially, are apt to overlook the exceeding beauty and usefulness of many annuals in gardens, and amongst these there is the charming Swaa River Daisy (*Brachycome iberidifolia*). I saw this growing in quantity the other day outdoors, where on a flower border it was beautiful, flowering profusely 4 inches in height and in large 60-sized pots, in which seed had been sown very thinly, not less beautiful, though just a little taller, in a cool greenhouse. The flowers much resemble those of the star-like *Cinerarias*, and are about 1 inch in diameter. Seed should be sown in pots early in April, and outdoors in rows or tiny clumps at the end of April. This Daisy

house all the winter, bloom gloriously in the spring in pots.—A. D.

WAYSIDE GARDENS.

MUCH of the pleasure in a country ramble has its source in the wayside gardens that edge the road in villages and country towns, or here and there in solitude face some remote lane. They vary from the comparatively large enclosure fronting some old red brick or stone house standing well back from the road, unpretentious in its aspect, but with an air of solid comfort and respectability, to the narrow, pebble-edged border flanked from the road, which may be seen in front of white-washed Dorsetshire cottages. These latter reflect great credit upon their originators, for even if the road at the base of the cottage wall is loosened with a pick and some of the metal cleared away, there is but little root-run, yet by heaping up the soil, using a good proportion of manure and assiduous watering, a bright display is contrived. A little humlet,

south-west plants not hardy enough for more northerly districts can be used with success, and in Cornwall *Solanum jasminoides* is often seen. Where this can be grown it is without doubt the finest flowering climber that we have, for its blooming period extends over six months. I once saw on either side of the porch of a Cornish cottage two huge bushes of *Salvia coccinea* fully 6 feet in height. In that county Myrtles are common on the cottage fronts, and the walls are sometimes mantled to the eaves with the Ivy-leaved *Pelargonium Mma. Crousse*. This is rarely much injured by the winter. *Cytisus racemosus*, which grows into a great bush in the south-west, and in mild winters is often in flower in December, is sometimes trained on the wall, and other rarer plants, presents from some large neighbouring garden, are occasionally seen. The well-to-do wayside garden is, though equally interesting, on an entirely different plane to the cottage plot. The house is often veiled with varied climbers, the paths are neatly gravelled or formed of flag-stones, and

A Gloucestershire farmhouse and front garden. From a photograph sent by Mr. W. R. Mills, Abington Farm, Fairford, Gloucester.

has a long blooming season, which can be extended if decaying flowers be picked off. If put into a bed which has been thickly carpeted with *Lobelia* or *Nemophila* it would be all the more charming. Of more tender annuals, I saw but the other day breadths of the varied and most lovely African *Nemesia strumosa*, the flowers of which give colours of unrivalled beauty. But the plants, whilst blooming freely and for a long season, yet have little foliage, and for that reason need some other plant to form a foliage base. Sweet *Alyssum*, *Limnanthes*, or *Nemophila* sown thinly would do capitally for that. *Nemesia* should be sown in shallow pots or pans and in colour, and be from these latter dibbled out into beds or borders where to flower. It is perhaps better to sow three or four seeds in 60-sized pots in fine soil, and thus raise several dozens of small clumps to turn out of pots. It is difficult to over praise the lovely colouring found in many of the flowers. The new *Schizanthus Wisetonensis*, with its charming butterfly-like rose and white flowers, is a hardy annual that cannot be too warmly praised. Seed sown in August, the plants kept in light for a week

each cottage in which is faced with a tiny flower strip such as described, is a pretty sight in early autumn, with its African Marigolds, Hollyhocks, here and there a scarlet *Gladiolus*, *Dahlia*, or *Chrysanthemum*. The gardens of one village generally show a certain degree of similarity in their contents. With trifling differences the same plants appear in each, evidently passed from one occupier to another. In another village a few miles distant another selection is probably in vogue, and it is extremely interesting in a 50-miles' bicycle ride to watch the variation exhibited by the cottagers' flowers as one passes from village to village. Where cottages have the inestimable advantage, both artistically and practically, of porches a now opening is afforded for its holder's gardening proclivities, for there are numberless flowering climbers that will wreath these with loveliness. *Jasmine* and *Virgin's Bower* (*Clematis Flammula*) are perhaps the most general favourites, but *Roses*, *Passion-flower*, *Clematis montana*, and large-flowered *Clematises* are often employed, and one of the prettiest I have seen was covered with the great white *Bindweed* in full flower. In the

formal beds are trimly edged. In looking into such a garden one is not seldom delighted with the flowers it holds—scarlet minks of white *Madonna Lilies*, beds of fragrant *Carnations*, of tenderly-tinted *Tea Roses*, clumps of old double *Rocket*, *Bergamot*, *Pansies*, *Love-in-a-mist*, *Irises*, *Mignonette*, *Stocks*, and *Lavender*, all of them beautiful and very sweet-scented. There are many other gardens of which much might be written—of the mill garden, with its *Paspalum Grasses*, its *Christmas Roses*, and *Mimulus* (yellow and blood-red), and the *Bulrushes*, *Willow Herb*, and *Loosestrife* around the mill-pool—of old-world inn gardens, and of the gardens of old Elizabethan manors now fallen in their estate to farm-houses. S. W. F.

Peruvian Lilies (*Alstroemerias*).—These are among our most showy herbaceous plants, and in the south-west are quite hardy, while in the colder parts of England, with a slight protection during the winter, all would be well with them, I think, especially if a fairly sandy soil and thorough drainage be afforded them. The golden varieties, no doubt, is the best

loer, and will thrive in a damper, stronger soil than the other varieties. All of them are grand for cutting, and stand a very long time in water. In light soils they require frequent watering during spells of drought in summer, and to be supported with branched sticks to keep the growth from falling over. I have found the less disturbance at the root the better for the plants. When it becomes necessary to remove them, early spring, just as growth begins, is the best time. They should be planted quite 6 inches deep. Here they will be secure against several degrees of frost if a few inches of sand or coal-ashes are placed over the roots at the end of November.—J. M. B.

ROSES.

MEDAL ROSES.

To me the most interesting of exhibits in an extensive show like that of the National Rose Society's display at the Temple are the medal blooms. These are collected from the whole of the stands, and the flowers so honoured are invariably perfect specimens. A silver medal goes to the best Hybrid Perpetual, Tea, and Hybrid Tea respectively, and in the two divisions—amateurs and nurserymen. Six flowers, therefore, are chosen. This year the finest Hybrid Perpetual was Mrs. J. Laing in both cases. These were very fine, splendidly developed blossoms. The best Hybrid Tea was a huge bloom of Mildred Grant in the trade exhibits, and Bessie Brown was the sort selected among amateurs. Maman Cochet, of the latter division, was that honoured as the finest Tea-scented; Cleopatra gained the other medal of this class. There is always some comment in regard to the medal Roses late in the day. It is not always remembered that the chosen blooms are considered the best when judged. It may be that they improve or lose in beauty as the day advances—mostly the latter—and, therefore, it is not surprising that other specimens which have improved are considered finer by the visitor. Thus, a splendid flower of Captain Hayward—one of the brightest of red Roses—and an equally fine Bessie Brown other than the one selected were much admired. Regarding these medal blooms, it is interesting to note that, with one exception (Maman Cochet), the sorts were raised in these isles. Mrs. John Laing and Cleopatra are the grandest of the choice varieties raised by the late Mr. H. Bennett. Mildred Grant and Bessie Brown are both from A. Dickson and Sons. The Gold Medal of the National Rose Society is also awarded to any new variety of exceptional merit. This year at the Temple two kinds were thought worthy. These were both Tea-scented—one named Lady Roberts, and the other Souvenir de Pierre Notting. The former is in shape the exact counterpart of an esteemed variety—Anna Olivier—but with deeper shades of buff and red tints. It is a charming Rose. Presumably, the latter is of French origin, although exhibited by Prince, of Oxford. The flower is not over-large, but the shape is first-rate. It is said to be a cross between Maman Cochet and Maréchal Niel. If that be so, it should grow to a large size to follow parentage. The combination of shades—yellow and pink—appeared to me its chief charm, and I should say it is a decided acquisition. H. S.

MAIDEN ROSES FOR EXHIBITION.

KINDLY tell me what Roses (exhibition) give best blooms as maidens, H.P. and H.T.? Also which exhibition Teas are best on standards, and which on dwarfs? Which are the best new exhibition Roses, and those a small amateur should go in for? I have 600 stocks (200 Manetti, 100 each of seedlings, standards, and cuttings) to bud now, and am anxious to do so to best advantage for next year's shows.—O. K. D.

[There are certain varieties of Roses that are only good for exhibition upon one-year-old or maiden plants, as they are termed, but if such varieties are budded where they are to remain they will give very good flowers the second and subsequent years. Of these varieties the principal are A. K. Williams (B), Horace Vernet (B), Xavier Olibo (C), Marchioness of Dufferin (M), Gustave Pignoneau (M), and Duchess of Bedford (B). These are all splendid show kinds, and several of each should be budded. There are also many Roses that produce good

flowers as maidens and also as cut-backs—a term usually employed for Roses that have been pruned back. If you desire to enter the larger classes at the shows you should grow five to ten each of the following as maidens, for not only do they produce splendid individual blooms, but they also come a little later than the cut-backs, consequently they are of more service in an early season. The following list should be grown: General Jacqueminot (M), Comte Raimbaud (C), Jeannie Dickson (M), Mrs. Sharman Crawford (M), Marie Baumann (C), Alfred Colomb (M), Caroline Testout (M), Etienne Levat (M), Duke of Fife (M), Frau Karl Druschki (M), Gladys Harkness (M), Mrs. John Laing (M), Robert Scott (M), Mrs. W. J. Grant (M), Mme. Jules Grolez (B), White Lady (B), Tennyson (M), Prince Arthur (M), Mildred Grant (B), Bessie Brown (B), Papa Lambert (B), Victor Hugo (B), Charles Lefebvre (M), Helen Keller (M), Suzanne M. Rodocanachi (M), E. Y. Teas (M), La France (M), Dupuy Jannin (M), Marchioness of Londonderry (M), Margaret Dickson (M), Duke of Wellington (M), Marquise Litta (C), Pride of Waltham (C), Tom Wood (C), Ulrich Brunner (M), and Antoine Rivoire (B). The following are best as cutbacks: Francois Micholon (C), Her Majesty (B), Mme. G. Luizez (M), Exquisite (B), and Mrs. Cocker (B). If you bud a few of each of these you will stand a good chance of carrying off some of the prizes, provided skill is employed in cultivating.

Tea Roses for exhibition are best from half-standards, and, if possible, I would advise that they be so grown, although certain kinds will produce fair blooms from dwarfs. These are marked with an asterisk. *Catherine Mermet, *Bridesmaid, Cleopatra, *Devoniensis, *Mme. Cusin, Mme. de Watteville, *Souvenir d'un Ami, *The Bride, *Mme. Hoste, *Souvenir d'Elise Vardon, *Souvenir de S. A. Prince, *Niphotos, *Anna Olivier, Innocente Pirola, Ernest Metz, *Medea, Maman Cochet, and *White Maman Cochet. The best new exhibition Roses are: Frau Karl Druschki, Mme. Vermorel (S), Boadicea (S), Mrs. Edward Mawley (S), Mildred Grant, Gladys Harkness, Bessie Brown, Exquisite, Papa Lambert, Dr. F. Gnyon (S), Lady Moym Beaulere (S), Duchess of Portland (S), Tennyson, Ben Cant (S), Lady Roberts (S). All of the kinds named would do well on the Brier, but for your guidance I have placed a letter against each kind indicating the stocks that give best results. For instance, B for seedling Brier, C for Brier cutting, M for Manetti, and S for standard or half-standard.—ROSA.]

NOTES AND REPLIES.

Pruning Roses.—Immediately after flowering, the climbing Roses against the house (Gloire de Dijon, Bouquet d'Or, W. A. Richardson, and others) send up long shoots 5 feet to 6 feet long. Ought I to cut them off or top them and nail them up?—GLOUCESTER DUKE. [Nail them in so that the wood can get well ripened, as on this depends the blooming next year.]

Rose Robert Scott.—Among the newer Roses this is not the least striking. It is a large, well-formed flower of a good type. The colour is a flesh-pink, with an exquisite finish to the petals. It is a cross between Mrs. W. J. Grant and Merveille de Lyon, raised in America, and not much known. It was seen in grand form at the Windsor Show the other day, and is one that should be noted by those who cultivate Roses for exhibition. It is said, too, by the raiser to be a good one to force and for pot culture generally.—H.

Pruning Marechal Niel Rose.—I have a Marechal Niel Rose in my small greenhouse. It flowered well this spring, and has run all over the house. It is not very robust. What had I better do with it now—prune it, or wait till autumn? I have a Niphotos just the same. What should I do with it?—REV. H. GOSSE.

[As a rule, strong-growing Roses planted out or grown in pots under glass are best pruned immediately after flowering, but this more especially applies to old established plants that have become quite a thicket of growth. In such cases some of the oldest shoots or branches are cut quite out, retaining as much as possible of the growth of the current season. By letting in sunlight and air to the shoots they are enabled to ripen off better, which is a necessary condition for the future success of the plants. Should your plants be much crowded with shoots, we would advise thinning at once, by cutting into the vacant spaces, the young shoots.

Any further pruning, such as shortening the lateral growths, will be best done in the early part of next year.]

Rose Fisher Holmes.—Few dark-coloured Roses have held their own like the splendid variety named above. It is what exhibitors term undersized, which perhaps renders it all the more useful to the novice, who, above all things, admires a shapely bud. And then its colour is so good. Fisher Holmes is a first-rate autumnal, blooming well and late, and is one of the few good H.P. crimson Roses to grow for that purpose. As a maiden plant the flower is superb, although small, the centre high and pointed, good alike on Manetti or seedling Brier, but more enduring on the latter. It makes a tolerably good standard, although I prefer Roses of a freer growth to standards—in fact, the more semi-pendulous the shoots the more graceful are these standard Roses.—ROSA.

Rose Noella Nabonnand.—I believe we have in the above a very fine climbing Rose, and one likely to be sought after. It has the beautiful rich velvety shading so much admired in Bardou Job, and (this is not to be wondered at, seeing that the variety under notice resulted from a cross between that Rose and Reine Marie Henriette. In the bud state Noella Nabonnand is lovely, and when fully expanded the large, semi-double blossoms are particularly showy. A wall covered with this Rose should be a splendid feature, and it is equally valuable for arch or pillar. One can also imagine what a glorious free-headed standard the Rose will make, especially if worked on a tall stem.—ROSA.

Climbing Roses for north wall.—Could you give me the names of two yellow or white climbing Roses suitable for a north wall? I often see Reine Marie Henriette praised in your columns. Here it does not do well. When in bud it is good, but when out all the colour goes.—T. S.

[As a nearly white Rose, you could not do better than plant Mme. Alfred Carriere. It is a splendid free kind, with large, showy, and very fragrant blossoms. In this position it should succeed well, and its not over-double flowers are very lasting. Celine Forestier is another reliable kind, pale yellow in colour, and one of the good old Roses that will probably never be surpassed. Commence well by cutting back the plants to quite half their length the first season, and, if they are nice bushy plants, we would advise you to cut one or two growths quite close down to the base. These, in course of time, will send up new shoots, and thus well furnish the wall. Reine Marie Henriette, as you say, is rather disappointing at times. We much prefer Waltham Climber No. 1, and also Waltham Climber No. 3. Cheshunt Hybrid is good on a north wall. In the bud no Rose is prettier, but when expanded the colour is not pleasant. Whilst the climbers are making growth you could well plant one or two of the dwarf Teas among them. Marie Van Houtte we have seen in such an aspect flourishing admirably, and doubtless others of similar strong habit, such as Mme. Hoste, Medea, Anna Olivier, etc., would also do well.]

Rose Mildred Grant.—No new Rose of recent years has created such interest as this, at least among exhibitors. This season has seen it in even better form than last year, when it was grown by the raisers only, Messrs. Dickson, of Newtownards. It is absolutely faultless as a show Rose. Its great size and charming shape, with attractive pink shades on a white ground, make it a variety all growers must have. It is a Hybrid Tea, and, like those kinds of that class, a free bloomer. If not rampant, it may be termed a good grower, with capital foliage. This variety has won more medals during the past two seasons for the best single flower than any other, old or new.—H.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Miss L. Bland, Carroney, Belfast, for Azalea and Holly; 2, Miss Mabel Gaisford, The Grove, Dunboyne, for Inias against Yew hedge.

TREES AND SHRUBS.

KALMIAS.

Among the dwarfier evergreens there are few better than the Kalmias. The genus is purely an American one, extending from the Arctic regions in the north to as far as Cuba in the south. The Kalmias belong to the Heath family, the flowers being rather flat and saucer-shaped and borne at, or near, the ends of the previous season's branches. They require the same conditions under cultivation as the great majority of their allies—the so-called "American" plants. A soil of a peaty nature is best, but in gardens consisting of pure loam

cuttings may also be employed, but seeds are preferable.

Both *K. angustifolia* and *K. latifolia* may be used for forcing. The plants should be potted up at the beginning of winter, and may be brought into the forcing-house at intervals to provide a succession, but slow and gentle forcing is necessary.

K. angustifolia is a very pretty dwarf shrub, growing from 1 foot to 3 feet high, and flowers during June. The flowers are of a purplish-red (but of different shades), each a little under half an inch in diameter, the corymbs being produced in the leaf-axils near the ends of the shoots, sometimes extending several inches downwards from the tips and

and useful as an edging for a group of the taller Kalmias.

K. A. VAR. RUBRA has flowers in which the purplish tinge of the ordinary form gives place to a purer red. Of the several varieties it is the richest in hue.

K. GLAUCA.—This species differs considerably in general aspect from the other two, and compared with either of them, but especially *K. latifolia*, is poor and scanty in appearance. Out of flower it is by no means so handsome a shrub. The glaucous white colour of the under surface of the leaves renders this species easily distinguishable. The flowers are reddish-lilac, each over half an inch across, and produced in terminal corymbs. The species was introduced from the United States in 1767. It is in flower, as a rule, early in April, and is thus two months or so in advance of its two fellow species.

K. LATIFOLIA.—This, commonly known as the Mountain Laurel, is much the largest of the Kalmias, and may frequently be seen 6 feet or 8 feet high in this country, whilst in the Southern Alleghany Mountains it is said occasionally to attain a height of 20 feet. It is a very handsome shrub both as regards its foliage and blossom, and in places where the conditions suit it there are few evergreens of greater beauty and value. The flowers appear in June in a cluster of corymbs terminating the shoot. Each flower is about three-quarters of an inch in diameter, and is rose-coloured. The shade varies in depth in different plants, and the flowers are sometimes almost white.

K. L. VAR. MYRTIFOLIA is a distinct and very pretty plant, of dwarfier habit, and its leaves are not much larger than those of the Myrtle. The flowers, also, are smaller than in the type, but the whole plant when in bloom is as pretty as it is neat and compact.

K. L. VAR. POLYPETALA.—In this the foliage does not differ from that of the ordinary *K. latifolia*, but the corolla, instead of having the usual saucer shape, is divided into several segments, as the name implies. It flowers each year at Kew at the same time as the others.

The Mountain Laurel (*Kalmia latifolia*).

Lonicera japonica.—This name includes the different forms of one species of Honey-suckle which are variously known in gardens and nurseries as *L. chinensis*, *Halleana*, *flexuosa*, and *brachypoda*. It is just now one of the most charming shrubs in flower, alike for the luxuriant elegance of its growth and for the sweet, strong fragrance of its blossoms. It is a climbing plant, but by giving it the support of three stakes 6 feet or more high, arranged on a tripod, it will form a dense, graceful bush, and may in this way be used to furnish the open border. It has broad ovate leaves, each from 1½ inches to 3 inches long, of a beautiful rich green. They are opposite, and a pair of flowers is produced in the axil of each one, so that four flowers appear at every joint. At first they are creamy-white, but gradually become yellow with age. The fragrance is like that of our native Honey-suckle, with a suggestion of Cowslip added. In mild winters this *Lonicera* is evergreen. It is a native of China and Japan.

Veronicas.—It is a great pity these charming plants are not more hardy in this country, as they make a grand show towards autumn. They are found in imbecile bushes throughout Devon and Cornwall and grow like weeds. It is best to give them a sheltered position and where plenty of sun can reach them to ripen the wood. Pruning should be done before growth begins in spring, and they grow in any good garden soil, most of the varieties increasing tenfold by seed in the counties named above, though they are easily rooted by taking cuttings in autumn and treating them similarly to *Pentstemons*, *Calceolarias*, etc., planting out in nursery lines early in April, when severe frosts are past. Most of the varieties are of a bluish tint, though a few are white and one or two reddish in colour. There are over 100 varieties, many being suitable for the rock-garden, and in localities where they do not prove hardy they are very suitable for pots, all they require being protection from very severe frost, standing outdoors from April until they come into flower, where they make a good display in a cool greenhouse. *Veronica Anterior* variegata is

they may be grown well by trenching deeply and mixing plenty of well-decayed leaf-soil and as much peat as can be afforded with the top spit. They have the same antipathy to lime at the roots, which renders the cultivation of so many ericaceous plants in chalky soils a difficult and expensive matter. A cool and continuously moist soil is an important desideratum, and this is why deep trenching is recommended. In hot, sandy soils the ground should be removed to a depth of 2 feet and replaced at the bottom with the best of the natural soil mixed with a heavier loam, filling the upper part with a mixture of peat, leaf-soil, and loam. All the three species here mentioned ripen seed in this country, by means of which they can be increased by layers and

forming a showy cylindrical shaped mass of blossom. It is a very free-flowering plant. It was introduced in 1736 from Canada, but extends from those southwards to the hills of the Carolinas. Of the several named varieties a cultivation the most distinct is

K. A. VAR. OVATA.—This, a native of the mountains of New Jersey, is easily distinguished by its larger, oblong or ovate leaves, which almost suggest a small-leaved *K. latifolia* in their glossy green colour and firmness of texture. The leaves are produced in whorls of three or four at each joint, and the whole shrub is of taller, more robust growth.

K. A. VAR. NANA is also a distinct and very pretty plant. It is of close, dwarf growth, forming a neat, dense bush 1 foot or less high,

a useful dwarf plant for edging in the flower garden during summer, and is also at home in the front row of a bank of plants in the greenhouse throughout the year.—J. M. B.

VEGETABLES.

PLANTING IN DRY WEATHER.

MANY consider that the best time for planting such things as Broccoli, Winter Greens, Savoys, Lettuces, and such-like is during the time of, or immediately following rain. No one will deny that it is much more easy to carry out such work under these favourable circumstances, but what of long spells of drought, when there are vacant spots put out of use by the maturity of their early crops? It certainly is not true economy to allow plants to remain crowded in the seed-bed while there is vacant ground on which they may be planted. It would be feared by some that to disturb plants in tropical weather such as that remembered in early July would spell failure in the attempt to get them established in new quarters. Such, however, is not the case if watering is possible for a few days. In dry weather there is much to gain in having firm ground to plant in, and, indeed, it is folly to dig in midsummer for the planting of winter crops. Rather plant or sow a crop that will mature in time for the ground to be cleared and dug in winter. Previous to lifting plants from the seed-bed, a good watering would be helpful. In old Strawberry-beds, from which the plants, weeds, and straw litter have been cleared, an iron bar will easily make suitable holes for the insertion of the roots, and, if these are well watered in, it is surprising how well moisture is retained. Necessarily, the plants will suffer and put on a poor, starved look for a time, but directly new roots take possession of the firm soil they soon make amends, and once they are well started further watering will not be called for. The evening is the better time for planting and watering, and, if the latter is repeated for about a week, the plants will then be self-supporting. I do not hesitate to plant in any weather, provided there are suitable land and seedlings to put out. When the soil is very wet and firm, the dibber makes a hole with smooth sides that is impervious to the free passage of air and water, and, as a consequence, neither roots nor plants progress with any degree of satisfaction. Those who may have been fearful of the attempt to plant Broccoli, Savoys, Winter Greens, etc., in dry weather may soon become convinced if they keep them watered for a few days and the ground is firm.

W. S.

TOMATOES SETTING BADLY.

IN some localities there is much complaint from growers of Tomatoes, who bewail the lightness of their crops through their failure to set. The cause of this is not very clear, because while one garden has suffered from this failing in a marked degree, in another it will be practically unknown. My indoor crops have never been heavier, and the same freedom would appear to characterise the outdoor plantings. While this is true of one case, several can be cited where the opposite is much in evidence. If the early indoor stock had displayed this stubbornness it might have been better understood, but when the failing follows each batch outdoors as well as those under glass it becomes at once a puzzling problem. Some of my plants have given crops averaging 10 lb. on a length of about 7 feet of stem, and these confined to boxes. The trusses were not more than 6 inches asunder, showing clearly the short-jointed nature of the growth. These were grown in a span-roofed house, and trained close to the glass. I find it advantageous, in dealing with Tomatoes in boxes or pots, to stand them where they can root through the bottoms into a bed of ashes or soil. It is not always practicable to do this, but is mentioned so that any of your readers who have the means placed within their reach may do so. I find that when the soil is exhausted in the boxes or pots the later set trusses suffer from lack of the needful support. On the other hand, if roots can escape through the bottom into some material, and coal-ashes in particular,

these late trusses become quite as good as those earlier formed. Cinder-covered stages maintain a state of moisture beneficial to any plant, and this same provision affords conditions exactly suited to Tomatoes. My span-roofed house accommodates a crop of Tomatoes at the same time as a stage full of plants, and all do well together.

W. S.

NOTES AND REPLIES.

Peas failing.—I enclose you some roots of Peas, and will be glad if you can tell me what is wrong with them. I never saw Pea roots in this state before. The entire sowing was the same. They grew badly all along, flowering later than they should, and were midwived very early. They followed a crop of Broccoli, and were spring sown. I should like to know if it would be possible to avoid this again and its cause?—F. WATT.

[It is difficult to say what is wrong with the roots of your Peas. The little nodules or excrescences on them are formed by certain bacteria, and are beneficial to the plant, as they assist it in obtaining nitrogen; but there was grub at the roots, which was probably that of the Pea-weevil (*Sitona lineata*), which would certainly injure them, but there must have been a great many to have really injured the crop. I should think that the inclement weather and, perhaps, aphides, had more to do with the failure than anything.—G. S. S.]

Early Potato disease.—As far as my experience goes I have never seen the disease so bad at this early season as this year. In a general way, when the atmosphere is favourable for its growth, I generally look for disease in the early part of July, and have noticed it often in such seasons from the 6th to 10th. I never remember seeing it before the 4th. But to my surprise it was visible in a field here on the 25th of June, and now, July 12th, many of the plants have not a green leaf on them. It made its appearance first on some of the early American kinds, amongst them Early Puritan. I observed it first on a patch in a close, hot corner, and not 50 yards away, where the air could circulate freely, it is not half so bad. I had an idea that if air could circulate among the plants this would ward off disease. It is clear crowding of leafage is to be condemned, but evidently this will not prevent it. In this field I have a quarter of an acre of a very late kind, and the tops have not grown enough to meet in the rows, yet the leaves are spotted as if hot water had been thrown over. In our village, on a hillside in the allotment gardens, the foliage is gone and the tubers are not larger than big marbles.—J. C., Forde Abbey.

Tomatoes in pits and frames.—Capital crops of Tomatoes may be secured in pits and frames, and any which may have been utilised for Potatoes or such like crops may well be used for Tomato growing. Varieties such as Early Ruby and Conference are excellent kinds for frames, not being strong growers, and also setting and swelling off heavy crops under such confined space. If the frames have already been occupied with Potatoes, no other preparation of the soil is needed. Before planting, a trellis should be erected, so as to bring the stems up to the glass. This trellis must also be close enough to prevent the fruits falling through. A trellis will be found a much better plan than allowing the stems to trail upon the surface of the bed, and then having to support the trusses of fruit—no easy matter. Squares of glass may be placed under these, but, on the other hand, these cause a condensed moisture to form under the fruits. Plant out along the front of the frame, training the stems slantwise. Sufficient shoots may be allowed to form without crowding, keeping all superfluous side growths promptly removed. Even if the frame should not already have been occupied with Potatoes, it is an easy matter to place a ridge of soil along the front, keeping it in position by a board or bricks. In this confined space the plants will require abundance of water and also feeding to swell off the crops. Do not attempt at any time to sprinkle overhead and close up the frame with sun heat, thinking that the plants or fruit will be forwarded, as on account of the sudden lowering of the temperature during the night and the stagnation of the atmosphere, disease is very apt to appear. Keep a little air continually on, increasing it more or less during the day, and reducing in the same ratio.

GARDEN WORK.

Conservatory.—Many greenhouse plants will now be in the open air, but they will require as careful management as when indoors, especially as regards watering. There is less danger of over-watering in dry weather, but the position the plants occupy will have some influence upon the supply of water required. At any rate, all plants in the open air should be looked over twice a day in hot weather. It is better to wait till a plant is dry, and then give enough to moisten all the soil. To anticipate the needs of a plant in this respect is not wise. Dewing over the foliage of Azaleas and other plants in the evening, when there is no dew deposited, is beneficial. No one should water a valuable specimen hard-wooded plant without testing its condition by tapping the sides of the pot. This is the best and surest test. Those who want Mignonette during autumn and early winter should sow soon seeds of any favourite variety. Machel is perhaps as good as any, but the size of the flowers is pretty much a matter of cultivation. The soil should be composed of good loam and leaf-mould, with a little old cow-manure, a sprinkling of bone-meal, and a dash of old plaster and soot. This would make an ideal compost for Mignonette when well blended and made firm in the pots. To some this mixture may seem needless trouble, but very few grow really good Mignonette. Sow the seeds thinly in 5-inch pots, or sow fewer seeds in 3½-inch pots, and shift into larger pots as required. Several sowings may be made during the autumn. Bulbs for forcing should be ordered early, and those intended to be forced early should be potted on arrival. Roman Hyacinths are much dearer than they were a year or two ago. It has been hinted that growers, or some of them, are forming a combine to raise prices. If so, they will have to keep the bulbs, as they are not necessary of life. What are termed Dutch Romans are very useful, and are cheaper, but will not force so well as the French Romans; but, if potted early, they will flower early, and this also refers to such bulbs as Freesias, which should be potted at once for early flowering. Double Daffodils, also, should be potted early for forcing. The permanent plants in the conservatory must be kept moist. Camellias especially want nourishment during the formation of the flower-buds. Weak soot-water will be useful to them and other things now.

Stove.—This is a good season for thoroughly cleansing the interior of the house and painting, if necessary, as the plants will take no harm if moved to another structure till the work is finished and the smell of paint passed away. It is far more difficult to grow plants well in dirty houses than in those which are clean and sweet, and insects also are more troublesome where the houses are dirty and in bad repair. This also is a time of ripening and resting, and more air should be given and the water supply in some cases reduced. Plants intended for table decoration during the autumn and winter should now be in 5-inch pots. Young, well-grown plants are the most suitable, and will include Crotons, Dracaenas, Caladiums, Cocos, and other small, neat Palms, and other dwarf plants of neat habit. The plants are usually grown in sets where much table decoration is done, giving as much change as possible. Among suitable flowering plants dwarf plants of Poinsettias, Begonias, Gesneras, Rivina humilis, and a few Orchids, such as the Cypripediums and some of the Dendrobiums, may come in the winter as a grateful change. In addition to plants, suitable foliage will be required, and a good stock of Asparagus plumosus and A. Sprengeri will be wanted, as also long trails of Smilax. Croton leaves are used a good deal in some places, and this means, of course, that large plants are in stock. Rather small but well-grown Maiden-hair Ferns are useful, especially that best of Maiden-hairs, A. Farleyense. All this means, of course, thoughtful attention and energy, with suitable places for their growth. Small, low places are best for these and other young stove plants.

Cold-frames.—There is seldom any resting time for these useful moveable structures. Now they are filled with Cucumbers, Melons,

Cinerarias, Cyclamens, Primulas, and various other young plants making growth. For the shade-loving plants it will be better if they can be placed in a shady spot with a couple of inches of ashes in the bottom. Worms in the pots are a great nuisance, and every effort should be made to keep them out. If a plant stands on the bare ground without an impervious foundation, worms will enter and soon block up the drainage. This is where the evil comes in. Though worms are useful as drainers in the open ground, they make wretched work in a pot, and should be cleared out with lime-water, or, better, their entrance prevented, which thoughtful men bring about by the bed of ashes or a foundation of boards, tiles, or slates. Plants in frames require abundant ventilation: in fact, on warm nights remove the lights altogether and let in the general night dews. Cuttings of many kinds of soft-wooded plants will root in the cold-frame now; and in a frame in the shade of a wall or fence, Pinks, Carnations, and choice evergreen shrubs may be rooted.

Ripe Grapes, if left too long on the vines will shrivel, unless shaded, and black Grapes lose colour and freshness if exposed to a hot, drying atmosphere. If there is a good Grape-room, ripe Grapes should be cut with suitable lengths of stem and placed in bottles of water in such a way that the bunches of Grapes hang free and clear of everything. In this room, with an occasional look round with the scissors, Grapes will keep longer than if left on the vines, and the houses may be thrown open to complete the ripening of the wood, or, if the lights are movable, they may be taken off as soon as the wood is firm and hard. The Grape-room must be ventilated, and no dust should be raised by sweeping, etc.

Orchard house.—Stone fruits will be getting plentiful outside now, and the trees in pots may be placed outside to ripen the wood when the fruits are all gathered. During the autumn any trees which require more pot-room should have a shift, and those not rejected should have some of the old soil removed and a top-dressing applied. No fruit-trees, even when its wood is finished for the season, should be left without moisture in the soil, or the buds will suffer.

Window gardening.—Window-boxes will be benefited by a little stimulant in the water. Fuchsias, Balsams, and other plants in flower, either in the house or in pots or tubs outside, will require some help now. Ferns and Palms must be shaded from the sun. Anything which requires repotting should have attention now if at all this season. Remove dust and insects with the sponge.

Outdoor garden.—There is a good deal of disease among patches of *Lilium candidum*, but away in the country, where they never buy imported bulbs, they seem healthy enough in the cottage gardens. Spraying early in the season with a fungicide seems the best remedy. Bordeaux-mixture, or sulphate of potassium in solution, $\frac{1}{2}$ oz. to the gallon, if used in time, is effective. It is best not to transplant very often, but the best time to move this Lily is immediately after the flower-stems die down early in August. Seeds of any choice plant should be looked after, gathered, and placed in an airy room to complete their ripening. Among the shrubs in flower now, the St. John's Wort are interesting, and the hardiest of them, *Hypericum calycinum*, is one of the best plants for covering the ground in shady places where other things will not grow. It is now in flower, and a wide patch of it is very effective. *H. Moserianum*, a taller-growing species with smaller flowers, makes a good group at a time when flowering shrubs are scarce. Among the shrubby Spiraeas, *S. arifolia* is very effective and graceful. Its habit of growth also is good. With a little pruning after flowering, a pyramidal outline will be given, which is more suited to its large, drooping sprays of white flowers. Somehow the season seems out of joint in the manner and time of flowering of many things among the hardy plants.

Fruit garden.—When the Peaches are gathered it is a good plan to cut out any old wood which is not likely to be required. This lets in the air and helps to ripen the wood. The young wood of Raspberries should be

thinned, leaving only enough of the stoutest canes for next year's bearing, and as soon as the fruits are all gathered cut out all the old canes. The autumn-bearing Raspberries should be tied to stakes or a trellis formed with wires to keep the fruit off the ground. If Red or White Currants on north walls are covered with hexagon netting they will keep fresh for a long time to use for tarts with the autumn-bearing Raspberry. I have kept them good till the end of November in mild seasons. A few bushes of Red Warrington Gooseberry may be preserved in the same way for some time. The old Strawberry plantations not required for next season's bearing may be chopped over with the spade and the rubbish burnt, the ashes scattered about, and the land planted with late Broccoli, if there are strong plants reserved which have been transplanted. In some districts Apples and Plums are falling from the effects of drought. This might be mitigated by a soaking of water and a rich top-dressing. Liquid-manure or house sewage will be useful, or a dressing of nitrate of soda watered in will be a great help in swelling off the fruit. In some gardens Strawberry runners are difficult to get in sufficient numbers, and in some instances older runners which were pricked out last autumn have been utilised, but strong runners of the current season are best.

Vegetable garden.—In our district the ground is hot and dry, necessitating mulching and watering. As regards mulching, when the manure supply fails other things may be used, such as the decayed vegetable matter or old potting soil, and sifted ashes among Lettuces and Endives check evaporation and keep the earth cool, as well as put a stop to the work of snails and slugs. Where the land is in good heart if the hoe is used freely to break up the surface this of itself forms a very useful mulch over the roots of the plants, and is a great encouragement to growth. This is the time to sow Winter Spinach, Tripoli and other kinds of Onions. Lettuces, Endives, Turnips, Radishes, and French Beans should now be sown in a frame to be sheltered from frost during the autumn. Liquid-manure may be given as freely as the supply will permit of to Celery, Leeks, Cauliflowers, Globe Artichokes, Lettuces, etc. Lift all early Potatoes as they ripen, and the land will come in for more of the crops named above, or may be prepared for Strawberries. If there is a surplus of Scarlet Runners, gather the pods of suitable size and place in earthen jars, with layers of salt, for winter use. Sow seeds of Telegraph or some other good Cucumber for planting in a warm house next month for winter use. In the meantime have the house thoroughly cleaned inside and whitewashed with hot lime, and, if necessary, painted. Keep the growth of Tomatoes thin, but do not remove any of the main leaves. E. HOBNAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 11th.—Made a further sowing of Winter Spinach and Onions. The necks of the forward spring-sown Onions have been bent down to increase the size of the bulbs. Cut down Pelargoniums and put in cuttings. Sowed Mignonette for autumn and winter blooming. Our new plantation of Strawberries will this season follow the earliest lot of Potatoes, which have been cleared off and the ground dressed with soot and a little bone-meal lightly forked in. The ground was trenched and rather heavily manured for the Potatoes, so nothing further is required now.

August 12th.—Finished layering Carnations and Picotees. The soil will be kept moist to hasten root formation. We are still doing a little summer pruning to fruit-trees, including a little thinning to Gooseberries where the young wood is crowded. The young canes in Raspberry plantations have been thinned, leaving only the requisite number for next season's bearing. We shall increase our stock of Superlative next autumn, so all available young shoots suitable for transplanting have been left. Apples are falling a good deal; but they will have a good crop, and can spare

August 13th.—We have been busy putting in cuttings of various plants for next season's bedding out, so it has been necessary to give some thought to the necessary changes in the arrangement, and we always like to make a few changes so as not to have the garden always the same. Begonias have been rather a strong feature, and Cannas will be more used in future, special attention being given to the preparation of the beds. It has been necessary to water some beds of moisture-loving plants, but we do as little watering as possible, trusting to mulching in some form and deep working.

August 13th.—Paper collars have been placed round Celery and the forwardest Leeks to help the blanching. We have always more or less potting to do, as many young plants are propagated and grow, and these require shifting on from time to time. Winter-flowering things especially are receiving attention now. A good batch of winter-flowering Begonias, including *Gloire de Lorraine*, has been placed in 5-inch pots in a pit. Cyclamens, also, and Primulas are for the most part in 5-inch pots. Heracleous Calceolarias have been pricked off into boxes, and Cinerarias are ready for shifting on.

August 13th. The hulls intended for forcing were ordered when catalogues arrived, and the first batch of Freesias and Roman Hyacinths has come to hand and will be potted immediately, and double Daffodils will have attention as soon as possible. The budding of standard Briers has been finished, and attention will be given to the dwarfs at once. A spare frame has been prepared for cuttings of choice evergreen shrubs; it is placed on the north side of a wall and the soil specially prepared. Peaches are gathered before they are quite ripe and either packed away or placed in cool fruit-room.

August 16th.—Sowed more Brown Cus and All-the-Year-Round Cabbage Lettuces. As plants become large enough they are transplanted to suitable positions. Transplanted a bed of Parsley to a warm site, where a frame can be placed over it in winter. All the bottom leaves were removed before planting and a good soaking of water given after. We always find this bed useful in winter, and it is generally reserved for bad weather. Made a further sowing of Turnips for winter use. Roses in beds have received a soaking of liquid-manure to help late blooms.

BEEES.

Earwigs in hives (*G. S. Stubbs*).—It is very rarely indeed that earwigs enter a hive. They, however, very frequently take refuge in coverings of straw hives where sacking or like material is used. In the case of frame hives, earwigs sometimes take refuge between the quilts or coverings of the frames, and, although they do no harm, it is not pleasant to have insect life in such close proximity to the honey. In this case, the renewal of the quilts will usually banish them from the hive, while, if they frequent the floor-board, a thorough scraping and cleansing of the same will prove effectual. Where straw hives rest upon a floor-board, a slight application of paraffin to the edges of the hives will keep earwigs at a distance.—S. S. G.

LAW AND CUSTOM.

Sale of land subject to a right of way.—Can a field be sold subject to a right of way to a meadow beyond it "As used and enjoyed by the owner and occupier heretofore," when that way has been closed for forty years and there is no indication of it on the plan attached to the conveyance, and all evidence in field and fence is lost, a permanent hedge and ditch running where the gate and posts must have been? Or does the fact that the owners of the field were also tenants of the meadow the whole time relieve the owner of the meadow of all his responsibility in seeing that his tenants keep the right of way open through their own land, although they did not need to use it, and permit him when they sell their field and give up his meadow to compel his new tenant of the meadow to cut a wide way through the hedge which was passed into the hands of the new owners of the field, and cast his crop across it as if there had been no break of forty years?—E. A. W.

The owners of a field are at liberty to sell that field subject to any right of way they may think proper to reserve or to grant, whether to

the public or to individuals or to the occupiers of certain lands. On the facts stated, there might be a question as to whether the owner of the meadow had or had not lost such right as he previously possessed, but I take it from your statement that the field in question has been expressly sold subject to such a right of way, and no purchaser or other person can deny the right of the vendor to sell subject to such right. The owner of the meadow cannot compel his tenant to make a way through the hedge of the meadow, still less to cast his crop across it, whatever that may mean, neither can he himself do these things; but if the occupier refuses to do it, the owner of the meadow may give him notice to determine his tenancy, and when he has resumed possession may exercise his right in such way as he thinks fit.—K. C. T.]

United Horticultural Benefit and Provident Society.—The usual monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi-terrace, W. C., on Monday evening, July 14th. Mr. C. H. Curtis presided. After the minutes of the last meeting were read and signed, four new members were elected. The death of a member was reported, and the amount standing to his credit in the ledger was granted to his nominee. A request for assistance from the Convalescent Fund was granted to a member who has been ill for a long time. Four members were reported on the Sick Fund.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in this column free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING ILLUSTRATED, 11, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING ILLUSTRATED is sent to a large number of subscribers, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Weeds on lawns (R. D.).—The ground was probably foul with the seeds of weeds before the Grass seeds were sown. All the annual weeds, such as Groundsel, may be destroyed by mowing the tops off frequently, never permitting them to run to seed. This is the most expeditious way of getting rid of them without injury to the Grass seeds.

Mildew on Roses (O.).—Roses are often mistlewed from being planted in a wet, heavy soil, with the surface hard and close from much treading. If the ground be well drained, and the surface often stirred, mildew will seldom give much trouble. When it does so dust flowers of sulphur over the affected parts as soon as it makes its appearance.

Raising Cobaea scandens from seed (R.).—Bottom-heat is not absolutely needful for raising seeds of Cobaea scandens. The seeds will come up in an ordinary greenhouse. Seedlings will bloom the same season, but the seed must be sown early in the year in a warm house, so that good, free, strong plants are ready for planting out in a cool greenhouse by the beginning of May.

Insect attacking Roses (H. W.).—The insect attacking the leaves of the Roses is the grub of one of the Sawflies. Syringe the bushes with soft-soap and Tobacco-water, or soft-soap and the extract from boiled Quassia-chips. In the winter remove the soil from under the bushes to a depth of 3 inches, and burn or bury it deeply. This will kill the chrysalides, and so prevent an attack next season.

Propagating Sweet-scented Verbenas or Lemon-plant (Aloysia citriflora) (V. P.).—This sweet-scented plant may be propagated from cuttings taken from the old wood in March, or the young shoots when firm in August. In either case cover with a bell-glass, and shade from bright sunshine. Let the soil for the cuttings be a mixture of loam, leaf-soil, and sharp sand, and this, when put in the pots, should be sprinkled with water before the cuttings are inserted.

Annuals for windows (R.).—For a potting compost about equal parts of good loam and leaf-soil will suit the greater part of them. It is necessary to be very watchful in regard to watering them, as, if allowed to become dry when young, many annuals run to wood, or woody in character. Other matters will be stated in due season when they are allowed to get into that state.

useless to attempt to put much further growth into them. Annuals in pots offer some advantages over permanent plants for window decoration, as one does not regret throwing them away when done with, so quickly can they be replaced with others.

Camellias—pruning (Mrs. M. Kildale).—Camellias should have what pruning is necessary immediately after flowering, but, as a rule, camellias in pots do not require much pruning. If the plants are planted out and the roots in good condition you may prune them if it is necessary to keep them within bounds, but the mere cutting of the blooms is, as a rule, all that is really necessary. If in good health leave them alone.

The Algerian Iris (Iris stylosa) (Algeria).—This is quite hardy, but the flowers are so delicate that unless the position is well sheltered you ought to protect them. It flowers in midwinter, the flowers being hidden in grassy foliage. Its silky, rhy-lily, fragrant flowers are very useful for cutting. There are several varieties, including a white form. They all require very light, warm, well-drained soil or raised borders. The other specimens you send are too dried up for us to hazard a name.

Araucaria albens (syn. Phylanthus albens) (Stejneger).—This is a pretty greenhouse climber that flowers freely towards the end of summer and in the autumn. The slender twining stems are clothed with leaves of a peculiar whitish tint, the flowers, borne several together in the axils of the leaves, whitish. It is a native of Brazil, whence it was introduced in 1830. It is easily raised from seed sown in heat in the spring, using sandy loam and fibrous peat. It has flowered and fruited in a garden in the open air near Dublin.

Wireworm in Carnations (A. B.).—Your Carnations have been attacked by wireworm. Many remedies have been given to destroy them, but it is too late after the Carnations have been planted out. The best way is to give a dressing of gas-lime, fork it in, and let the ground lie fallow for a year, frequently stirring it in the meantime. You may put slices of Carrots on the end of pointed sticks, burying the Carrots 2 inches or 3 inches in the soil. Examine these daily, when the wireworm will be found on the Carrot slices and may be destroyed.

Mealy-bug on Clematis (A. E. Harrison).—Without seeing the insect you refer to, the only conclusion we can come to is that the Clematis has been attacked by mealy-bug—one of the worst plant pests we have. Well syringe the plant with paraffin emulsion, the recipe for making which is: 1 quart soft-soap, well mixed in 2 quarts of boiling water; while hot add 1 pint of paraffin, and mix well with a syringe, then add ten or twelve times the quantity of water. When using see that this is kept well mixed to prevent the paraffin coming to the surface. See note re Mealy-bug on Vines, in our issue of August 2, p. 300.

Roses refusing to expand (J. L. M. Rhyll).—Generally speaking, varieties having thin petals are the worst in this respect. Heavy rains saturate the flower, and the petals, being so thin, become stuck together, which the sun, if it shines, seems powerless to prevent. Such Roses should really be shaded. They are too full of petals. If planted near a wall this trouble would not occur so much, if at all. It really pays to have a number of neat shades at hand ready to place over blooms of great merit, for it is very disappointing after watching the progress of the growth to find the flower-buds refusing to open.

Climbing Roses (C. Kirk).—1. As you already possess so many first-rate kinds it is rather difficult to suggest others, but we think you will find Climbing Kaiserin Augusta Victoria, Celine Forestier, and Mme. Alfred Carriere three valuable kinds. 2. It is not easy to name a Rose for contrast to Gloire de Dijon, but either Monsieur Desir or Longworth Rambler suggest themselves. The latter is freer, but the former is the better flower. Waltham Climber No. 1 is also a splendid bright red climber, similar in habit to Gloire de Dijon, but not quite so perpetual. 3. Clustered Roses of fast growth are Felicite-Perpetue, Flora, Virginian Rambler, and Ruags, all good, but should select in order given. The Garland and Mme. d'Arhley are two splendid pillar Roses.

Plants for sheltered spot, etc. (R. J. C.).—Your suggestion to sow Grass seeds should be carried out at once, but the evergreens could not be planted yet for some weeks. Could you not also add such things as Hollyhocks, Sunflowers, Perennial Pea, Delphiniums, and other showy plants to help to hide the wall? Or, if the latter be roughly built, why not other seeds of all flowers, Snapdragon, Fuchsia, Asterias, Poppies, etc., and sow in the crevices mixed with soil? These things would give a floral beauty quite unusual. Plants suitable to the wall are many—Sedums, Saxifragas, Corydalis lutea, Achillea umbellata, with Silver and Gold Thyme. These things, if planted in early autumn—say September—and kept fairly moist, soon take to their respective places, and give satisfaction generally.

Garden Pinks (W. M.).—The following rank amongst good faced or show Pinks, the edgings of the petals being red or purple: Jessica, John Ball, Lancer, Boiard, Modesty, Mrs. Pettifer, Tottie, Derby Day, Ada Louise, Bertram, Emerald, and Master Harry; of border kinds, suitable to furnish flowers for cutting: Mrs. Sinkins, Her Majesty, and Albino, white: Anne Boleyn, Asot, Ernest Ladhams, Paddington, Diamond, Godfrey, Hebe, Lizzie Duval, and Charles. These latter mostly have dark centres and white or coloured ground. Whilst the faced or show Pinks need special culture, some being "timid," the border Pinks generally are fairly robust. All can be propagated freely from pipings or cuttings, put into sandy soil under a handlight in June. Single are best got by sowing seed, as from that plants come freely. Of Male Pinks, the old one and Napoleon III. are the best, and almost the only ones. Transplant Pinks in October or November.

Iris Kamperi seedlings—treatment of (Bodford).—As the seedlings become large enough you had best pot them, say into 3-inch pots, and give them pot treatment for a year. Then for another year you had best plant them out in a frame or pit, or in a specially prepared bit of ground in a cool, sheltered, and partially shaded spot, where frequent waterings and sprinkling overhead can be given them. Even the young seedlings thoroughly appreciate liberal care, rich and deep

soil, with plenty of moisture, so long as this does not haze about them. The size of the plants will be the best guide as to when they are fit to plant permanently; but in any case, when you plant them, do not make the common error of doing it in late autumn or winter, early spring, April, being one of the best months in the twelve. Do not throw the seed-pot away until you are well assured you have the majority of the seedlings, as frequently quite new seeds do not vegetate all at once, or with uniform regularity. Place the seed-pots in shady corners or in a frame, but if no seedlings appear by the month of March, place the pots in a warm greenhouse till they appear. By this means a longer season of growth in the first year will be assured.

Sweet Peas failing (A. B. H. S.).—Without seeing your garden we cannot satisfactorily explain the cause of failure. From the specimens sent to us, however, we should attribute the cause of failure to a want of moisture to a large degree. They have a poor, dried-up appearance, such as one meets with in gardens which lack a proper supply of water, and without copious applications of water it is not possible to cultivate the Sweet Pea so satisfactorily. In view of what you say regarding the ground being "thoroughly well prepared beforehand, and at time of sowing in excellent order," we cannot very well attribute your failure to the poor condition of the soil, and yet in our own garden we have grown the Sweet Pea on the same ground for several years, and have never yet had to record a failure. To do these matters the ground must be thoroughly well tilled. Deep cultivation is essential to success, and heavy manuring must be regarded as an accompaniment. Sowing so late as mid-May, and this followed by the abnormal weather of the present season, you could not very well expect to have strong, healthy plants within a period of six weeks. Your absence from the garden during the period referred to is probably responsible to a considerable extent for the failure, constant overlooking, as you no doubt know, being an important item in one's system of culture. We should advise you to raise your plants in pots in future, giving them rather cool treatment after the seedlings are through the soil. Plant them in clumps 3 feet apart, taking out the soil round the soil filling in with half or half a barrowful of good manure. We are confident you would succeed with this method.

FRUIT.

Seedling Oranges (S. B. Elliot).—Your seedling Oranges may be years before they show any bloom. The Orange plants sold by nurserymen have all been grafted with good kinds, and this is the only way to ensure early fruit bearing. Any gardener should be able to graft these for you.

Grapes "rusting" (M. B.).—The Grapes are badly attacked with "rust," which may arise from an over-heated fire (the house being heated by fuel, causing an escape of sulphurous fumes when the berries were young and tender, or they were rubbed with the hair or brush when being thinned. But we think the overheat fire is the cause.

Filberts and Nut-trees (E.).—The chief thing to attend to in their management after the trees are established is their pruning, and you would do better than take a well-managed Gooseberry-bush as a model, only, of course, the former will be many times larger. A low, wide, spreading bush, producing abundance of short, stubby, fruitful spray is the thing most desired.

VEGETABLES.

Maggot in Potatoes (Alec).—The maggots among your Potatoes doubtless were brought into the soil in the cow manure. When you have lifted the crop give a dressing of unslaked lime, and ridge up the ground for the winter. This, we think, will disperse them.

Scabbed Potatoes (F. Fowler Ward).—It is quite clear what is the cause of scab in Potatoes, you inclining to the opinion that it is a form of fungus. We think the fungus is only an accessory, arising from the broken condition of the skin brought about by some unknown cause. It is generally held that the scab depends on the absence of lime in the soil, and that a good dressing of this is very helpful. No doubt your soil would be all the better for a good lime dressing. Never use any manure which there are wood shavings, as the decayed wood sets forth ferment in all fungus diseases, and may be the cause of the scab in the case of your Potatoes.

Woodlice in Mushroom-bed (C. Booth).—From the specimen of Mushroom you send we think you will find that the culprit are woodlice, to get rid of them trapping is the only cure. Place some Potatoes, cut in half and hollowed out, in their haunts. They will congregate on the Potatoes, and may be destroyed by plunging into boiling water. If you can get their haunts at the bottom of a wall or in other positions, they may be killed by pouring boiling water over them. You can also get bricks, tiles, or boards near their haunts, under which they will creep, and may then be collected and destroyed.

Poultry-manure for vegetables (M. F.).—This manure may be spread over the soil and be dug in it as last as it is made, or it may be mixed with refuse and heaped, and be permitted to lie until somewhat sweetened. It is not good material to make liquid-manure of, the best way to rather it is to cover the floor of the front-hoop with sifted ashes, and then rake off the droppings every other day. In this way the floor is kept clean, and the manure is easily removed. Mixed with ashes it soon dries and works freely.

Sleeping disease in Tomatoes (H. B. Pollard).—Your Tomatoes are suffering from what is known as the "sleeping disease," caused by a fungus, Fusarium imperfectum, the spores of which attack the delicate root hairs and rootlets of the plant, finally invading the whole of the roots and spreading up the stem. The treatment recommended is that directly a plant is observed to droop it should be pulled up and burned, the soil also in which it has been growing being removed and mixed with lime. Are they growing in the same soil as you had them in last year? If so, this tends to disease, as Tomatoes do well must have a change of soil every year.

Pulverising clay soil (Farmers).—To get clay soil partly sweetened and pulverised by the use of a hot-plate on it in October heaps of fresh lime, at the rate of one bushel per rod. Just cover up each heap with soil described from close round, and very soon the lime will

rest and slack, bursting the soil covering. Then at once spread it evenly over the soil and dig it in. You should find most useful street sweepings, especially such as contain much horse droppings. If you could work that, some 3 inches thick, into the clay it would do good. So, too, will lawn Grass mowings, stable manure, tree leaves, or other such material. Great good results also from making up a wood and coal fire in the garden, and placing some of the clay over it. In that way in the course of the winter many cartloads can be charred, and should then be spread over the soil and dug in.

Beans and Broccoli (Garden Lover).—The reason why your Runner and Dwarf Kidney Beans make gross escape and pod very late is no doubt due to the greatly enriched and, perhaps, damp nature of the soil, and, no doubt, also too much shade. If these are not the causes, and they are the common ones in such cases, then there would be some peculiarities connected with your garden of which we know nothing, and cannot indicate unless you had further information. What you describe as a Purple Broccoli is doubtless Early Purple Cape Cauliflowers, these will occasionally button or produce tiny heads prematurely, but few persons grow them now. Such varieties as Snowball, Mammoth, and Autumn Giant, all white ones, are much superior. If you refer to the Purple Broccoli, nothing is more unusual than for that to flower prematurely. If it be that, pinch out the flower, and make the plants break afresh.

SHORT REPLIES.

Lozenges.—Put the cuttings at once into pots, stand in the open air, and when well rooted move to a room from which you can keep out frost. Keep fairly dry during the winter and pot off singly next spring.—*A. Constant* under "Gardening Illustrated."—See reply to D. S. M., re "Mildew Grapes." In our issue of July 12, 1902.—*Cyclamen.*—See note in our issue of February 22, 1902, p. 678, as to the value of rotted leaves. Peat is only used for hard-wooded things, as Heaths, Azaleas, etc., and peat-bark-fibre is employed for plunging plants in, and serves well as a mulching to retain moisture.—*Anon.*—You cannot do better than plant Sweet Briar, Honey-suckle, climbing Roses, Mock Orange, Choleya ternata, Camelia, Forsythia, Aloyria citriflora, and Magnolia. There was no signature to your query.—*Stueser.*—1. Get Hobday's "Villa Gardening," from this office, price 6s. 6d., post free. 2. Yes, if you incorporate some rather heavier soil at the time of planting. 3 and 4. Consult our advertisement columns.—*A. B.*—Your Rose is not sufficiently well established to perfect so many blooms; pick off the flowers and encourage the plants to grow freely.—*W. G. Callahan.*—You will find the recipe for destroying worms on lawn in our issue of May 17, p. 161. Your lawn

evidently wants draining.—*P. J. W. Fear.*—See note under heading "Imported Orchids in New Zealand." In our issue of June 21, p. 218. The photo you sent was, unfortunately, not clear enough for reproduction.—*N. J. H.*—It is very difficult to assign any reason without seeing the fruit, but from what you say we should imagine that your Peaches have split stones. See reply to "S. J. A." in our issue of June 14, p. 209, re "Peach-trees Casting their Fruit."—*A. N. T.*—Impossible to advise without further particulars as to size of house, etc. The temperature you give is that kept up in a stove, and if we were to recommend greenhouse plants such a house would be far too hot for them. It is too hot for Tomatoes.—*H. M.*—You had better get Shaw's "Market Gardening," from this office.—*J. W., Cambridge.*—There is practically nothing to be done in the way of killing slugs but hand-picking.—*R. J. C.*—See reply to "Wildbrook," in our issue of August 2, p. 301.—*D. McCallum.*—You give us no particulars as to the soil, etc., in which the Peas are growing. We should imagine they have been sown too thickly, causing mildew, while they are probably dry at the roots, and have fallen a prey to red-spider.—*L. H.*—Your Grapes have been badly affected by mildew. See reply to "D. S. M." in our issue of July 12, p. 282, re "Grapes Mildewed."—*Inyranus.*—Difficult to say without further information. Rose query will have attention.—*Miss Elizabeth J. Bennett.*—The best thing you can do is to well syringe the plant with some good insecticide, paraffin emulsion being as good as any. The recipe for making this has recently been given in our pages.—*A. K. Cockburn.*—The best and only thing you can do is to trench the ground, and in the operation to clear out every piece of root you can find.—*A. B. Todd.*—See article on "Air Roots on Vines" in our issue of July 5, 1902, p. 244.—*Lazol.*—Your Rose has been severely attacked by mildew, the best cure for which is dusting well with sulphur. Your Begonia and Gloxinia leaves have been attacked by thrips, which fumigating will destroy.—*W. L. W. Boidie.*—Try giving the wire arches a coat of white lead paint, as the acid from the zinc is injurious to the young growths of any plant. Peaches often suffer in this way.—*J. Burtenshaw.*—No need to be alarmed. The leaves of Gros Colman Vitis assume the colours yours have when dying off. In your case this may have been hastened, as we find traces of thrip and red-spider on the leaves.—*Greenmount.*—The leaf looks as if it had been scorched. Are you quite sure that the plant has not been allowed to get dry, or did you fumigate when the foliage was damp?—*Knowe.*—Kindly make your query plainer.—*A. P. Davison.*—It would be advisable to cut down the spike when it is fading, as by doing this you will strengthen the plant.—*T. H. P.*—In the word Polygonum the second o is short, as in the Greek word for knee.

NAMES OF PLANTS AND FRUITS.

*. * Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—*B. G. I.*—*Spiraea confusa.*—*Don.*—*Lathyrus sylvestris.*—*Ebric.*—Flower quite shrivelled up, but evidently a Clematis—probably *C. montana.*—*N. D. P.*—*Arum liliaceum.*—You can do nothing to change the colour or destroy the offensive odour; 2. The Calla must have a very moist position; 3. Try the white forms of *Lilium speciosum.*—*F. Guardia.*—*Gloriosa superba.*—*Tenny Beginner.*—*Bloo Cupidone* (*Catanacho corulea*), easily grown in any soil and quickly raised from seed.—*David Jones.*—2, *Lysimachia vulgaris*; 3, *Tropaeolum polyphyllum*; 7, *Spiraea Bumalda*; 8, *Aconitum Napellus versicolor*; others next week.—*D. McCallum.*—*Lysimachia vulgaris.*—*A. H. J.*—*Stachys lanata.*—*E. Arnold.*—We cannot name florists' flowers; Plinks are propagated by pipings or layers immediately after flowering.—*A. B.*—Quite impossible to name from such scraps as you send.—*E. W. Page.*—We cannot undertake to name from such specimens as you send us.—*M. K. C.*—Kindly send better specimens, with numbers affixed to each. See our rules to correspondents.—*Miss G. Elkington.*—*Campylopus alliarifolia.*—*F. L. S.*—1, *Sedum album*; 2, *Echinochloa frutescens*; 3, *Spiraea filipendula* fl. pl. 1, 4, Send in flower.—*Tyneville.*—*Diplazis glutinosa*; easily increased by cuttings.—*B. T.*—1, *Cape Leadwort* (*Plumbago capensis*); 2, *Habrothamnus slossans*; 3, *Paest. flora* sp.; should like to see a piece of the growth as well as a bloom.—*T. H.*—1, *Verberis barwinii*; 2, Please send better specimen; 3, *Achillea ptarmica* fl. pl.; 4, *Solidago virginica*; 5, *Achillea millefolium* rosea; 6, Send in flower; the *Asparagus steni* you send is what is known as *fasciated.*—*Smilax.*—Please send fresh specimens and affix a number to each, so that we may be able to identify them.—*Regular Reader.*—Specimen quite dried up.—*F. Wilson.*—1, *Agrostis* sp. (f) *canina*; 3, *Aira caespitosa*; 5, *Avena elatior*; 6, *florens* sp.; 7, *Dactylis glomerata*. You ought to have put the specimens through two sheets in the paper. The Fern specimen is insufficient.

Catalogue received.—Cooper, Taber and Co., 90 and 92, Southwark-street, London, S.E.—*Wholesale Bulb Catalogue.*

CAMBRIDGE

LEMONADE

"BEATS ALL."

"AS GOOD AS CHIVERS' JELLIES."

That is very high praise indeed for the Cambridge Lemonade, because the Jellies are recognised to be the best that can be produced. Same firm, same high standard of excellence. The Lemonade is made from Lemons and Sugar. No foreign acid added. 5½d. per bottle. Goes

farthest. Ask your Grocer, or send 6d. for sample to Chivers & Sons, Ltd., Histon, Cambridge, where Chivers' Jellies are made.

The Cambridge Lemonade is carefully prepared from selected Sicilian Lemons, and is guaranteed to contain the natural refreshing constituents of the fresh ripe fruit, free from any added acid or other injurious ingredient.

5½d. per bottle, sufficient to make Two Gallons delicious Lemonade.

CHIVERS & SONS, LTD., HISTON, CAMBRIDGE. Original from URBANA, CHAMPAIGN, Proprietors of the First English Fruit Growers' Jam Factory.

GARDEN & PLANT PHOTOGRAPHS, 1902.

THE EDITOR OF GARDENING ILLUSTRATED announces Photographic Competition for the season of 1902.

Class 1.—SMALL GARDENS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best ten photographs or sketches of picturesque small gardens, including town and villa gardens, rectory, farmhouse, or cottage gardens.

Class 2.—FLOWERS AND SHRUBS OF THE OPEN AIR.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS to the sender of the best series of not less than twelve photographs of the above. These may include wild plants or bushes, or any plant, flower, or shrub grown in the open air, including also half hardy plants put out for the summer, and either single specimens or groups, or the objects resulting therefrom, in beds or borders. Shoots also of rare or beautiful plants photographed in the house may be included in this class.

Class 3.—INDOOR FLOWERS AND PLANTS.—A prize of FIVE GUINEAS and a SECOND PRIZE of THREE GUINEAS for the best series of indoor plants—greenhouse, stove plants, Orchids, or any other plant not of the open air—either single shoots, plants, or specimens, or the effects resulting from good grouping or other arrangements of such plants separately or in association with others. Ferns or groups of Ferns in houses may be included in this class.

Class 4.—BEST GARDEN FRUITS AND VEGETABLES.—A prize of FIVE GUINEAS and a SECOND PRIZE of TWO GUINEAS for not less than twelve photographs of the best kinds of garden fruits and vegetables, Grapes, Peaches, Apples, Pears, Plums, Cherries, or any other fruit grown in Britain, to be shown singly or on the branches. Overcrowding, as in dishes at shows, should be avoided. The aim should be to show well the form of each kind, and as far as may be life-size. The object of this is to get good representations of the best garden fruits and vegetables under the old names, though we do not want to exclude real novelties when they are such.

Class 5.—GENERAL SUBJECTS.—A prize of FIVE GUINEAS will be awarded for the best twelve photographs of any garden subject not included in the previous classes, such as winter gardens, waterside effects, rock gardens, picturesque effects in gardens, vases, cut flowers, table decorations, and pretty garden structures.

All competitors not winning a prize will for each photograph chosen receive the sum of half a guinea. In order to give ample time to prepare good photographs the competition will be kept open until November 29th, 1902.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with flowers. Figures of men or women, burrows, scattering pots, rakes, hoes, rollers, and other implements, iron railings, wire, or iron supports of any kind, ladders, and all like objects should be omitted from these photographs. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. The subjects should not be overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others, but the source whence they are obtained must be stated, and none the copyright of which is open to question must be sent. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly. Platinotypes and bromides should not be sent, but those on albumenized and printing out papers are preferred for engraving. All photographs should be properly toned.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. Care should be taken to avoid the ink being seen on the face of the photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor, 17, Farnival-street, Holborn, London, E.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." Unsuccessful competitors, who wish their pictures to be returned must enclose sufficient postage stamps for that purpose.

Patent Greenhouse BOILERS.

The special merits of our Boilers are—

- 1.—Long Burning.
- 2.—Even Temperature.
- 3.—No Trouble.
- 4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition.

Guaranteed Minimum Burning 12 Hours Without Attention

It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unsatisfactory Boilers can be replaced in a few hours' work without moving existing pipes.

EXTRACTS FROM LETTERS RECEIVED:—

"My gardener says he never had such a stove before so easy to work, and does its work so well." "Does it work splendidly, and is certainly the least trouble of any stove I ever had." "My maids manage it." "The last No. 2 I had from you always goes 24 hours at a stretch. I never look at it but once a day, and have a good fire heat the whole 24 hours."

VEGETABLES.

NOTES ON EARLY PEAS.

The past spring will long be remembered as altogether against vegetation; yet, in spite of the long-continued cold, sunless weather, Peas evidently did not mind it so much as many vegetables, and, though growth appeared slow above ground, the roots were active in laying a good foundation, so that when warmer weather came a reaction would set in, which certainly the case, for I do not remember greater roadway being made after the 1st of May and the first week in June. Our Peas cannot be called an early one, for, as a rule, it is from the 6th of June to the 12th of June before one can gather the first dish of Peas, but this year it was the 22nd, from the east border—not the best position for the first crop—but inside our walled garden fruit trees occupy the whole length of the southern wall, which deprives us of an early border. Our first gathering was from seed sown January 30th, while a row sown in the open on February 17th was but a few days behind that of the former. *Opinionos* differ as to which is the best to sow for an early crop—the dwarfs or the taller varieties—and, after giving both an extended trial, I prefer the dwarfs, and the one that has given me most satisfaction is *Harstoner*, truly a grand Pea for first crop, not reaching more than 10 inches to 12 inches in height, but literally covered with well-filled pods of good size, while the flavour is all that could be desired in an early Pea, and one that I can with full confidence highly recommend. *Chelsea Gem* is another favourite with me, a very heavy cropper, and of the finest flavour; this reaches over 2 feet generally with me. Then comes *Daisy*, which follows quickly in the train as a second early Marrowfat, with large, handsome pods well filled and of excellent flavour, and nearly 3 feet in height with this season, owing, no doubt, to the bountiful shower during May and early June, which greatly favoured the Pea crop. Of the taller kinds, *Exonian* and *Gradus* both do well with me, though the former is considered by many to be a bit miffy. It certainly is rather a weak grower, though it crops well and the flavour is right. In *Gradus* we have a Pea hard to beat as a second early, and I have no hesitation in saying it is one of the best and finest Peas in cultivation when procured true to name, and one we shall bear more of as time goes on. Dwarf Peas are often sown far too thickly—I mean from row to row. Instead of 2 feet being the maximum, much better results would be had if given another foot, while *Daisy* should have 3 feet 6 inches to 4 feet apart, and even the very dwarfest grower should be supported with bushy sticks, thus preventing the haulm getting crippled. In a future issue I hope to deal with maincrop and late varieties of Peas, the succession of which is quite as important to the gardener as that of earliness.

NOTES AND REPLIES.

Gourds failing.—I have attempted to grow Gourds this year with little success; most of the fruits drop off when well formed. They are placed in various parts of the garden in sunshine and shade, rich and poor soil, and they are all about on a level as to quality. Owing to the very late, cold spring, they were kept waiting too long in the pots, and the foliage began to turn yellow. They also had to weather some cold spells late in June. Do you think this check has caused the mischief? Is there anything specially to be guarded against in their culture?—P. M. G.

[The check you mention is, no doubt, the cause of failure, one great point in the culture being to keep them growing on freely until planted out. See note on culture of Vegetable Marrows in our issue of July 26, p. 286.]

Vegetable Marrows failing.—Would you kindly tell me in your next issue of GARDENING what is the cause of my Marrow-plants going like the enclosed? They are on a border facing south. The soil is light, about 1 feet deep, on gravel. I give them plenty of river water. I have tried them in different parts of the garden, both with and without water, and also by mulching and without, but they go the same. Sometimes one plant will fail, while the next one will be all right.—J. BRATSHAW.

[We have seen what is called the "yellows" very much in both Marrows and outdoor Cucumbers this year, and attribute it to lack of wurmth. These plants need plenty of sunshine. Yours is a plant of the Bush Marrow, and seems to be more liable to that disease than do the rambling varieties. Primarily the cause is found in root-stem gumming. The stem just beneath the soil splits and then the plants collapse. We have seen Cucumbers plants under glass suffer greatly in that way, and found the best remedy in the following year was to give them a stiffer soil. As yours is a light soil it may be that this is the cause of the gumming and splitting. The complaint is a common one, but, this season, being so general, we think it is more due to general low temperature and too much moisture than to any other cause.]

Potato Onions.—Would you kindly tell me the name of the enclosed—*Echallots* or *Onions*? I entered some of my best bulbs in a local show as *Echallots* (cottage's class), and they were rejected as not being *Echallots*; but neither of the judges could tell me what else they were. I have enclosed what was left of the seed-bulbs I purchased, and also one root just as they were lifted.—KIDDERMINSTER.

[The judges at your show were right in disqualifying you, as your bulbs were not those of Shallot, but were what are commonly known as Potato or underground Onions (*Allium aggregatum*) or the cluster-producing Onion. Bulbs have to be planted in November or March just as Shallots are, but need rather more room. They never flower. You must have noticed that the bulbs are rounder than are those of the Shallot. Many years ago these Potato Onions were commonly grown in gardens and used. That was before there were such fine ordinary or seed-raised Onions in commerce as we now have. The true old Shallot has a skin of the same colour as your Onions have, a pleasing nutty brown, and there is a form of it that has skins of a dull white colour. The large Jersey or Russian Shallot is red and coarser in texture than is the true Shallot. You should get bulbs of both to grow another year.]

Judging allotment gardens.—We have a garden allotment prize, and the gardens have been judged by the head gardeners. Twenty-three competed for six

prizes. Ought the competitors to see how many points each competitor had? Ought the judges to judge these vegetable gardens by the schedule, or could they give points for flowers, fruit-trees, etc., which are not in the schedule? Are there any rules for judging the best cultivated allotment? How is it that Runner Beans flower best without sticks?—GRANVILLE JOHNSON.

[When allotments are judged by points, and it is the only satisfactory way of doing so, the number of points given to each judged plot should be published by the secretary. At shows, generally, it is done by posting them on a large card at the entrance to the flower show tent. When you ask whether the judges should judge the allotments by the schedule, of course, they must, but as we do not know the conditions of the schedule, we cannot say whether they are justified in giving points to fruits and flowers which you say are not in the schedule. But if these things are not excluded, they should, of course, be judged. We hold that dwarf or bush trees, bush fruits, and Strawberries should be represented on any good allotment. So also should flowers, and we like to see a border some 6 feet wide full of flowers at one end of each allotment. There is no county in which allotment judging is better done than in Surrey. There the chief portion of the judging is done by the County Council instructors, who have great experience, as they judge several hundreds each year, and have their own printed lists of crops, etc., on forms to work by. They include every possible crop, and give a maximum of ten marks for such things as neatness, order of cropping. Some crops have a maximum of eight marks, according to value, and others six or four, according to their values, and not a thing grown in gardens or on allotments is overlooked. The results when totalled up are sent to the secretaries of the various societies for whom the judging has been done. This system inspires the completest confidence. Runner Beans begin to flower sooner if not staked, but then the crop is later and so much less. Good staked Beans carry three times the flowers and pods those do that are not staked. These Beans well repay deep soil and tall stakes.]

Runner Beans.—We seem likely to have a very short season with these most valuable Beans, as hardly a pod was gathered from plants raised under ordinary conditions during the month of July. Out of hundreds of rows I have seen in diverse places, many quite strong, 6 feet in height and freshly flowered, yet hardly in one case can good pods be found at the end of the month. This late cropping is due to the exceedingly prolonged coldness of the spring and early summer. How is that difficulty to be faced another year should similar climatic conditions prevail? No doubt it is wise to sow in some three or four dozen of small pots filled with good soil one *Beau* each, and raise them under glass. If that be done early in May, the plants should be 12 inches in height at the end of the month, and if then planted out into good soil in a warm, sheltered position, they should have a couple of weeks start over those sown in the open, cold ground. Of course, plants thus raised should be well hardened before they are planted out.

PLANTS AND FLOWERS.

INDOOR PLANTS.

FINE-LEAVED BEGONIAS.

THERE is now among the fine-leaved Begonias an infinite variety, some being suffused all over as with silver, whilst the combinations of pale green, dark green, bronze and silvery variegation in many kinds are beautiful in the extreme. Some of these form quite a picture of themselves and are well worth a study. These Begonias are most accommodating plants, being of free and vigorous growth. They are excellent plants for an amateur to grow in his greenhouse, where he does not let the temperature ever fall below 40 degs. For the stove and intermediate house they are also well adapted. Where a wall which is unsightly wants covering with growing plants these Begonias are first-rate material to use. All that they seem to require is just sufficient soil to establish themselves; after this their roots will ramify in all directions and cling to the bare wall, more particularly if it be bare brick-work. If the position be a damp and shaded one, these Begonias do equally as well or even better than under what might be thought to be more favourable conditions. If they are required to cover a dry wall, all that one has to do is to keep them well supplied with water. I have been particularly struck with the beautiful effect produced by their use in a planted-out fernery. Here the roots will delight to ramble and cling to the rockwork, particularly sandstone. Thus grown in a cool fernery they will generally retain their foliage all the year, looking bright and cheerful in the dull days of winter.

As pot-plants their value is pretty well known and appreciated for the decoration of plant houses. They also make capital decorative material for the house, in many instances being singularly appropriate to the surroundings. Small plants usually face all one way; thus they are well adapted for vases upon brackets, niches, or corners. They are most accommodating as to soil, but that which is light suits them best; mellow loam, leaf-mould, and sand answer well. Large pots are not at all requisite.

PROPAGATION is simple and easily effected by the leaves; all that one has to do is to prepare a pan with sandy soil, and then after cutting through the ribs of the leaves to peg one or more upon the surface of the soil, the outer portions of the leaves being cut away. Plenty of young plants will soon be the result. This is far better than the cumbersome system of dividing the older plants, whereby the beautiful effect of a small plant is lost.

PLANTS FOR COLD GREENHOUSES IN WINTER.

(REPLY TO "D. T.")

THE question raised is one beset with difficulties—viz., as to how one may have flowers in the winter time in greenhouses where there are no means of artificial heat. With most blossoms wanted between December and March it is a matter of heat at the disposal of the grower—the rest is easy, and mainly resolves itself into preparing plants, bulbs, etc., so that a succession of flowers may be kept up, bringing them into warmer quarters as circumstances demand. But with a cold greenhouse it is different. Here one has to make the best of things, and, as far as is possible, afford what protection one can in the severest weather. Very much, of course, depends upon the situation of the house itself, and, if I had to erect a cold-house, I would prefer a lean-to one having a south aspect, so that every gleam of winter sunlight would be taken advantage of. As already pointed out, bulbs, like

Hyacinths, Tulips, Narcissi, may be potted up this autumn, and to these may be added Snowdrops, Scillas, and Chionodoxas, some of our bulbs which, with the shelter of a house, will commence to bloom in the earliest days of the year. A glance at hardy plants will show us that there are many that bloom in the open, even in the darkest days of winter. Such are the Christmas Roses (the Hellebore), which, often from want of a slight protection, lack purity in their blossoms, but, covered with a frame-light or potted up, yield us most liberally unsullied flowers. If room can be found in the house, I would lift carefully in November plants of *Jasminum nudiflorum*, whose yellow blooms, often starved and pinched out-of-doors, are beautiful and abundantly produced with the slightest shelter. Fragrant flowers, too, must be thought of, and because the house lacks heat it does not follow that sweet smelling things shall not be grown. We think of that old shrub the Winter Sweet (*Chimonanthus fragrans*) and know how on many a wall it opens its blooms in the depth of winter, the scent pervading every room into which sprays of it are brought. This, too, is of service. I well remember also how pots of Neapolitan Violets brought under glass in October will bloom with equal freedom as in a frame, and Brompton Stocks and Wallflowers—flowers that for sweetness and prodigality of blossoms one would find it difficult to surpass—how by potting them in October one may have flowers for

A fine-leaved Begonia.

weeks before those out-of-doors show colour. Mention has been made, and rightly so, of *Azalea mollis*, which in the first days of spring lends a sweetness to a house, and the same may be said of Lilacs. One is reminded, too, of the Lilies of the Valley, Solomon's Seal, *Dieolytras*, and Irises, beginning with that earliest sort, *reticulata*, which need little more than a covering to bring them into bloom in the springtime slightly in advance of those outside. I have stated my preference for a lean-to house, if limited to a cold one, and my reason is that with a good wall at the back some protection is gained, and in severe weather a covering of mats, or blinds, or even brown-paper, will keep out a deal of frost, if it is not possible to exclude it nearly altogether, from harming the hardy subjects already alluded to, by using an oil-stove. Under any circumstances if there is a readiness on the part of people who have cold-houses to make the best of them, there is no any need for them to be entirely bare of flowers, for in making the most of those that bloom in the open, one may have Christmas Roses more pure, Violets, Wallflowers, and early Irises more sweet, and Jasmines more lavishly produced, and all of them weeks before those out-of-doors have unfolded their first buds.

LEAHURST.

NOTES AND REPLIES.

Cutting down *Nepenthes*.—I have some *Nepenthes* which are doing very well. I have been told that unless I either cut them back or cut off the pitchers, they will not bear pitchers another year. I shall be glad if you

will give me brief hints as to the culture of the same! And if they are to be cut back, what is the best time?—J. A. R.

[If your *Nepenthes* are doing well and have pitched freely you should neither cut them down nor cut the pitchers from the plants. September is regarded as about the best month in the year in which to see this section of interesting plants. After September the plants will begin to lose their pitchers from natural decay. The growth will also be less vigorous, consequently during the winter months, with cooler and slightly drier conditions, little advancement in growth will be made until the middle of February, when the lengthening days will stimulate the growth. As soon as this renewed activity is observed the tops of the growth may be cut off to within 5 inches or 6 inches of the base. Allow the plants to remain undisturbed in the old pots and compost until the new breaks appear. When these are observed the plants may be carefully turned out of the old potting compost, and fresh material, consisting of fibrous peat, living Sphagnum, a little leaf-soil, and plenty of rough silver-sand, given. Afford ample drainage. The coarse Bracken roots abstracted when picking the peat may be substituted for the crocks. Where the Bracken roots are used less water will be required. To increase your stock, the tops you cut off as above suggested may be made into cuttings in the usual way. These should be placed into pots of chopped living Sphagnum Moss and sand, or they may be plunged in a propagating case in which there is a brisk bottom-heat, where they root quickly. Another method of propagation is that commonly known as ringing—that is, take a knife and remove one of the leaves where the wood is in a half-ripened state; the point of the knife should be then inserted into the bark, drawing it about an inch on each side of the joint from where the leaf is removed in three or four places around the stem. Then bind some green Sphagnum, or a halved pot containing some moisture-retaining substance. Into this the plants will soon emit new roots, and they may then be potted up in the usual way. —H. J. C.]

Canas in pots failing to flower.—I have seven or eight *Canas*, which flowered the first year I had them (1900) beautifully in pots in the porch; since, though treated in the same way, they have never thrown out a flower-stem. The plants look perfectly healthy, and have plenty of good strong leaves. —ROSEVAX.

[Your *Canna* question is somewhat of a puzzle, for, as far as we can judge by your letter, the plants should flower freely. Is the porch a shady one? If so, this would account for the production of leaves at the expense of blossoms. It should be borne in mind that the *Canas* are liberal feeders and revel in bright sunshine, though during the flowering season the blossoms remain fresh longer if shaded. Some varieties, too, have a tendency to break up into many weaker crowns, and these flower much better if they are divided when repotted in the spring. We should think more exposure would result in the production of blossoms, and as these develop the plant may be removed to the porch.]

Azaleas not flowering.—My *Azaleas* last year did not bloom well, although treated the same as other years, and brought into the house by the end of September. Was it the change of temperature that caused the leaves to drop? I ought to say they were not repotted last year. —A. E. S.

[These plants lose a proportion of the older leaves each year—i. e., those lowest on the stems, twigs, or branches. If the loss of leaves is out of all proportion to those newly formed, then the plants have been more or less dry at the roots. This, if repeated a few times, would mean the loss of root-fibre in that portion of the plant affected, and the fact of the plants not flowering materially strengthens the view we have taken. All hard-wooded plants require great quantities of water, regularly applied at the moment of becoming dry. Small quantities given at any time, whether the plant requires it or not, are equally bad. Far better allow the plant to become nearly dry, and then thoroughly saturate by a double dose of water. Established plants of *Azalea* require a thorough watering daily in summer if in a sunny place in the open, being first examined to ascertain the condition of dryness.]

Carnations for winter.—I have a batch of *Carnations* raised from seed sown in early spring; they are now in 6-inch pots in an open frame. I want them to bloom during winter in the greenhouse. Kindly say if the

flower-buds now appearing should be pinched out? Any hints as to their treatment will be appreciated.—R.M.M.

[Your Carnations may belong to the summer-flowering race, in which case, if you pick off the buds now it is very probable that none will develop later on. Carnations are of different sections, and if yours belong more or less to the perpetual-flowering class they will continue to produce buds. Such being the case, we should advise you to let the flowers develop, as an autumnal display is preferable to none at all. With regard to the treatment, as your plants are in 6-inch pots, it is not very probable that they are full of roots, but if they are, a little weak manure and soot-water occasionally will be of service. Carnations in all stages need a free circulation of air, and in a stuffy atmosphere they are soon spoiled, hence, when taken under glass to develop their blossoms this fact should be borne in mind. The Carnations that bloom through the winter belong to what is known as the Tree or Perpetual-flowering class, the plants of which are struck from cuttings early in the spring,

ROSES.

ROSE MME. PERNET-DUCHER (H.T.).

It is freely conceded by all who have planted the Hybrid Teas in quantity that Mme. Pernet-Ducher is one of the best garden Roses we have. Its grand trusses of loose white flowers, the numerous carmine-tipped buds and half-open blossoms of pale canary-yellow, when massed, produce a picture not surpassed by any other variety of my acquaintance. It is such a splendid perpetual-flowering kind, and, like all semi-double Roses, especially beautiful in autumn, when its fine petals have a cooler season to develop. Some time ago I had a pillar plant of this Rose in a pot, and, when in bloom, I never beheld a more lovely object, the great white petals being so persistent. As a standard it makes an exceptionally fine head, not quite so large as *Gustave Regis*, but perhaps even more decorative, the plant being more compact in growth than this well-known variety. As a cut flower Mme. Pernet-Ducher

should be dug and some burnt earth, gritty sand, or sifted coal-ashes incorporated rather liberally. A layering trowel, quite flat and about 4 inches or 5 inches wide, 3 inches or 6 inches deep, is a very handy tool when layering Roses and shrubs. The trowel is inserted in the soil, and then the branch bent over towards the latter. It will then be seen where the cut in the branch must be made. I prefer that the cut part should be under the soil about 4 inches, and 4 inches or 5 inches of the branch should appear above. The cut is made in the upper surface of the growth. Commence to cut the bark near to a bud, and bring the knife in a slanting manner along the shoot for about 1 inch, then cut off extreme point of the tongue—i.e., the cut part. Fold the branch beneath the cut with one hand and gently bend it into the niche in the soil prepared for it by the trowel. Great care is necessary not to snap off the end of the branch. By making a sufficiently deep niche layering pins are not required. The soil is made firm after inserting the layer with the

Rose Mme. Pernet Ducher.

and grown on during the summer, the last portion of the time out-of-doors. In the autumn, when the heavy rains set in, they are taken under glass in a light, airy house, when, if kept free from aphides, the blooms gradually develop.]

Aspidistras.—There is no subject amongst fine-foliaged plants so popular as the *Aspidistra* for rooms, etc., and none that will stand—for a time, at least—apparent neglect. There comes a time, however, when it requires special attention; when, owing perhaps to close confinement or gas, the foliage turns yellow, and it needs a change. It is just then when the benefits of a greenhouse are most felt, and a few weeks will generally bring about the desired improvement. In the absence of a greenhouse the next best thing is to seek some other remedy. One of the best ways is to keep the leaves of *Aspidistras* clean by washing them with soap and soft water twice a week and syringing them occasionally. A little soot in the watering-can, or guano, will aid in keeping them in good condition, and air freely admitted to the room at this time of the year will be advantageous.—L.M.

is very lasting. I proved this only last week. A mass of the exquisite trusses was taken to a country flower show, and the next day I was able to stage them at another exhibition. A very showy bed of this Rose could be made by interspersing some pillars of Grass or Tepitz, loosely secured to 4-foot stakes or canes. The simultaneous flowering and the contrast in colour could not fail to have a fine effect. I do not, as a rule, favour the contrast form of planting on the one bed, but in this case make an exception. Rosa.

LAYERING ROSES.
(REPLY TO "E. M.")

Now is a good time to propagate Roses from layers. All old-fashioned varieties are very easily increased in this manner, and most of the present-day kinds too. It is necessary that the branches to be layered should spring from the base of the plant, and, of course, they should be fairly pliable so that stiff, erect growers are not so readily increased by layers. These had better be reserved for cuttings. Lay the plant to be layered the ground

handle end of the trowel. The stools should be watered now and then if the weather is very dry, but do not water the soil about the layers. Fine own-root plants are obtainable in this simple way in eighteen months.

Rosa.

EXHIBITING ROSES.

THERE is a growing dislike to the system of showing Roses in long lines of boxes. In fact, it follows the complaints noted in recent years in regard to *Chrysanthemums* and *Dahlias*, and changed methods are likely. Roses in vases are certainly beautiful, but there seems to us room in an exhibition for both arrangements. Show Roses are grown to their utmost size by good cultivation, the specimens are judged individually, and therefore we want to exhibit them in their most perfect state without a spot, in such a position that the eye of the judge shall best examine them. Boxes answer this purpose, and it would be a bold person who would say that this long established system has not been the chief element in making the Rose so popular as it is. But after noting the really grand cases of blossoms in

one or two instances at the recent Temple show one is forced to conclude that the Rose lends itself to other forms of exhibiting. Handsome, well-grown flowers are noble when arranged together and tastefully in suitable glasses. To my mind a big vase of the variety Killarney was quite one of the most beautiful things in the show alluded to. White Maman Cochet made another grand exhibit. In fact, it is the better kinds of Roses that are the most admired in whatever way they are shown. I do not care much for most of the so-called garden Roses. The best of the bunches as we see them exhibited are the choicer kinds of Roses in a badly developed state. If I were asked why people show garden Roses, I should say because they either cannot or will not grow Roses well. Rambling over a wall or trellis I can admire the lovely rambling Roses, but cramped in a bunch as we see them at shows they seem out of place—at least, in competition. I can also admire the charming Laurette Messimy in a mass, but this unless in a mass is not a Rose to care for. Roses in vases should be encouraged and extended in every possible way, and more especially at what may be termed country exhibitions. In this case those who compete are mostly near, and the blossoms may be taken without much in the way of packing. This question of the large amount of packing required to convey Roses with long stems a distance so that they shall not be damaged is one that, perhaps, will tell in favour of the older system of exhibiting.

S.

NOTES AND REPLIES.

Two yellow Roses for arches.—Kindly give me the names of two good yellow Roses suitable to grow on arches and a pink, but not the ordinary Ramblers, but strong climbing Roses.—P. B. S.

[Climbing *Porte des Jardins* and *Celine Forestier* are among the good yellow sorts suited to climbing or covering arches. *Alister Stella Gray*, though of not quite the colour, is a very charming thing in bud and blossom. To these may be added *W. A. Richardson* and the well-known and fragrant *Gloire de Dijon*. *Euphrosyne*, a *Polyantha* kind, with clusters of bright rose, semi-double flowers, is a good vigorous climber.]

Decayed wood on Roses.—I enclose two branches of Rose-wood and shall be glad if you will say what causes the old wood to rot in the way this has done? I have only noticed this on *Baroness Rothschild* and *Merveille de Lyon*. My house stands 500 feet above sea level, and the soil is a heavy clay.—IGNORANTS.

[It is nothing unusual to find growths partially decayed similar to those sent, and there are several causes, such as insect punctures, frost-bites, injury by gales, etc. In this case we believe the injury arises from the action of frost upon unripened growths. It is a great mistake to foster this old wood. Better far have only one well-ripened young growth than a lot of weakly old shoots. We should advise you to rid your plants more of the latter another year.]

Growing Crimson Rambler Rose.—Will you tell me the proper treatment of the *Crimson Rambler* Rose? Mine was a mass of bloom last year; this, though perfectly healthy, there is hardly a flower.—K. K.

[We fear there is a wrong impression abroad that this grand Rambler should have all flowering wood cut out after such growths have blossomed. It is true the young wood, if well ripened, will give the best trusses, but to obtain a really good mass of blossom one must have 2-year-old wood well covered with lateral growths. These latter are shortened at time of pruning, whereas the young rods are left intact. Growth more than 2 years old may be cut out with advantage, for this gives the remaining growths a better chance of ripening. If you had given us some information regarding the treatment of the plant since last blooming time, we could have told you where the fault lay; but we suspect that the flowering growths were removed too liberally.]

Rosa Felicité Perpetue, Baltimore Belle, and Dundee Rambler falling.—These Roses, after appearing particularly healthy and showing a tremendous number of buds in early June, suddenly went wrong, the leaves turned yellow and dropped off, and a large proportion of the buds rotted off. Is this the result of bad weather or bad treatment? If the latter, where did the fault lie?—AOK.

[You do not say whether the Roses were established or newly planted. And further you ask us if they were planted in the ground or in pots.]

treatment without informing us as to treatment they have received. Hardy Roses of this description should certainly not fail to thrive if the soil is in good order. Often, if there is stagnation of the soil, the young roots decay, and the result is as described. You had better replant in the autumn if they are worth it, but it would be safer to procure some new plants, and as these Roses may be readily obtained on their own roots, we should advise you to procure them in that form. When replanting have the ground well and deeply dug, adding grit and burnt earth if the soil is heavy.]

Diseased Roses.—Would you kindly say if red rust in Roses is shown by orange spots on the under sides of the leaves and on bare stalks by a sickly-looking condition of the bushes and the buds failing to open and putting off? If so, what is the cause and what the remedy? I have some Hybrid Perpetuals showing these symptoms badly. They are planted on a dry bank in a sheltered position.—AOK.

[You will find some remarks upon *Orange-fungus* in a recent issue of *GARDENING*. From your description we should say your plants have had attack of this troublesome disease. Hybrid Perpetuals on the *Manetti* stock are very prone to attacks of this fungus, which is rendered all the more acute in your case from the dry position in which the plants are. Where *Orange-fungus* continually gives trouble in this way, it is better to transplant the trees and bushes every third or fourth year, trenching the ground, and incorporating some lime or chalk, together with a liberal dressing of cow-manure. We should also advise you to procure more of the Hybrid Teas and Teas, and ask for them on the seedling Brier. This stock, from its deep-rooting nature, keeps the plants in a growing condition, whereas the *Manetti* stock ripens so very early. Where possible to obtain them, plant some of the Hybrid Perpetuals on their own roots; Teas and Hybrid Teas also, if you can get them.]

Moving Rose Fortune's Yellow.—I have a *Rose Fortune's Yellow*, which had to be moved, so was put down to about 5 feet. It is now standing out of doors in a pot, and is making a quantity of very healthy shoots, some now about 2 feet long. Would it do well on a south wall? It takes up too much room in the greenhouse. Also, should it be pruned much? It blossomed very little last spring, although it made tremendous growth. It is about three years old, and never blossomed at all till this year.—MRS. WILLOUGHBY L. COTTON.

[In your district this exquisite Rose should grow well outdoors, and we should advise you to plant it out without delay. It prefers a rather dry, well-drained soil, and one in which lime is present in a liberal degree. Do not break the ball of earth in any way. It would be better to plant it out now rather than allow it to remain in the pot, as it will then obtain a good hold of the soil before winter. Do not prune it at present. You will do well to spread out the growths that the sun may harden them. The plant may even not flower next year; if, however, you encourage growth and do all you can to thoroughly ripen the wood, you will be rewarded by a glorious mass of blossom later on. Should the plant produce a perfect thicket of growths next season, some of the shoots may be entirely removed to the great advantage of the remainder. *Fortune's Yellow* objects to being cramped in any way, so that a lofty wall is preferable, and unless this can be afforded under glass, it is a variety that should not be planted there.]

Roses for small greenhouse.—I have bought a small lean-to greenhouse, 12 feet 6 inches long and 9 feet 6 inches wide, and not having a wall against which I could erect it, I have decided to put it in the middle of my garden, and should like to convert same into a Rose-house. I have had no experience in Rose culture, and shall be obliged if you will give me your advice as to the best soil for and varieties to grow in pots? Would a *Marchal Niel* grow and cover the back?—AOK.

[You could not put the small structure to a better use than converting it into a Rose-house. For the centre of house a solid staging about 1 foot to 2 feet high should be built, the outer wall of the staging made of bricks and the inner bed of coal or coke ashes. The Rose plants could be placed upon inverted pots, and thus brought nearer the glass. Those known as extra sized pot-plants would be best to procure, but a smaller size could be purchased and potted on. They would do well, excepting that considerable time would be necessary ere you got any return. The best classes of Rose are the Hybrid Perpetuals and the Hybrid Teas, and a dozen good kinds, as named below, should give you variety enough.—MRS. JOHN

Laing, Ulrich Brunner, Fisher Holmes, Frau Karl Druschki, Caroline Testout, La France, Mrs. W. J. Grant, Marquise Lilla, White Lady, Admiral Dewey, Madame Ravary, Liberty. If you could wait a year, a good plan would be to purchase selected bush-plants from the open ground and pot them up into 8-inch pots this coming October, using a compost of two parts top spit loam and one part well rotted manure. Pot the plants firmly and plunge them in the open in a bed of ashes, protecting the plants from severe weather with some mats or Bracken Fern. Prune the plants in March, and still keep them plunged where they are until early in June, when they should be plunged into more open quarters and set well apart from each other. The plants will blossom outdoors about the same time as other Roses. Such plants are thus rendered fit for greenhouse work the following winter without any further preparation save pinning and top dressing with a little new soil. As regards *Marchal Niel*, we would advise you to prepare a border in the house and plant therein a dwarf or half-standard of this Rose. Such a plant will be ample for your small house. The border should be 3 feet deep and about 4 feet long, and 2 feet to 3 feet wide. Remove the old soil, put in bottom 6 inches of rubble for drainage, and then fill up the hole a foot above surface with compost such as advised above, excepting that it would be well to add a quart of bone-dust thoroughly mixed and incorporated with the soil. Prune the *Marchal Niel* rather hard the first season in order to induce some good long growths for flowering the following year.]

Rose Irish Glory.—No single Rose of recent years has pleased me more than this. We not only want single Roses early, but also late, and from the single Teas we may expect the latter. *Irish Glory* has the immense petals of the best Hybrid Teas, the colour a silvery pink with crimson shading. On a cool day the flower, ere expanding, is beautiful with its long pointed buds. It appears to be a good grower. What a lovely bed this would make edged with the pure white large-petalled single *Irish Beauty*!—W.

Rose Killarney.—It is most difficult to exaggerate the beauty of this charming Hybrid Tea. Seen on a cool day, its glorious broad-petalled, semi-double flowers are beautiful, but the finest phase of the flower is the extra long-pointed bud. In colour it is a flesh pink shading to a paler tint, with sufficient distinction from any other pink Rose to warrant its introduction to this numerous group. As an exhibition flower it is truly marvellous how such a thin variety maintains its beauty, the long blossoms refusing to fly open, as is too often the case with varieties of this description. On the plant is, however, the way to see *Killarney* at its best.—E.

Rose Liberty.—The more I see of this brilliant Rose the more I like it. That it is free-flowering cannot be denied—in fact, every new shoot is crowned with buds. It would be possible to have crimson Roses all the year round by a little management with a good stock of *Liberty*. Some pot-plants grown outdoors this year had their buds removed before they expanded, in order to encourage growth. These plants are now producing another fine crop of buds, just as the first bloom of the bush-plants is waning. Many of the Hybrid Teas can be treated after this manner. My suggestion is to have a double set of plants of a few of the leading kinds, such as *Mrs. W. J. Grant*, *Caroline Testout*, *Killarney*, etc. the one set being allowed to flower unhindered, the other set all the first crop of buds being removed when visible. By so doing, a break in the continuity of blossoming is avoided. *Liberty* will be a grand garden Rose, not so brilliant, perhaps, as *Marquise de Salisbury*, *Princess de Sagan*, or *Gruss an Teplitz*, but producing flowers of far more shapely form than either.—ROSA.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE AND GREENHOUSE PLANTS" or "THE ENGLISH FLOWER GARDEN," to the reader of the most useful or interesting letter or short article published in the current issue, which will be marked "AW".

OUTDOOR PLANTS.

EREMURUS ROBUSTUS.

The *Eremurus robustus* figured was planted October, 1900, and last year threw up a spike about 6 feet high; this year the spike measured over 9 feet, and the flowers were magnificent. Peach-shaded Lilac is a description of the

Eremurus robustus. From a photograph sent by Mr. A. P. Davison, Broughton Grange, Banbury.

colour. I find it quite hardy. This garden is 420 feet above sea level, and in the winter I lay some clean straw over the *Eremurus*, as the spike and foliage die down every year. I had to tie it on to a support this year as we had such winds in May. It was at its height of bloom on June 14.

ARTHUR P. DAVISON.

Broughton Grange, Banbury.

MINIATURE-FLOWERED TUFTED PANSIES.

This delightful race of plants lost its best advocate by the death of Dr. Chas. Stuart, of Chirnside, N. B. Many persons unacquainted with this newer race fail at first to appreciate their charming qualities, but when once convinced of their value, cultivators of Tufted Pansies soon become admirers of the miniature sorts. Until people come to recognise these plants as specially suitable for rock and alpine gardens, and also as plants for massing, the trade specialists will not make much of them. Dr. Stuart used to say that the miniature-flowered or *Violetta* type needs to be grown in the same place undisturbed for two or three seasons for its splendid qualities to be appreciated. Under conditions such as these the results are satisfactory, and readers of GARDENING ILLUSTRATED would be well advised to take in hand a limited collection of plants to begin with. The blossoms are sweet scented.

The miniature-flowered kinds are a very limited quantity, the craze for large flowers being the reason why these smaller-flowered sorts were to a large degree ignored, and in consequence many delightful flowers received but slight attention and were lost. The following brief descriptions of some I am now growing may interest readers:—

VIOLETTA.—Palo white, with a yellow suffusion on the lower petal. The blossoms are

good substance, and are slightly less than 1½ inches in diameter. It is very free flowering.

LADY IN WHITE.—Another very dainty white sort, having a neat yellow eye. The plant has a sturdy, tufted habit, and is a protuse bloomer.

QUEEN OF THE YEAR.—This is unique in its form and colour. The blossoms are circular in shape and have plenty of substance, the colour a distinct shade of china-blue with a whitish centre; free flowering.

GOLD CREST.—A pretty little yellow rayless flower, developed somewhat less freely than in most others, on plants bearing something to be desired as to habit. The blossoms are very small.

LITTLE PRINCE.—Of special value, as it is one of the very few sorts of a rich clear purple colour. The little blossoms are very dainty in appearance, and the variety should be included in this collection of six sorts.

PRINCESS MAY is a pure snow-white flower of charming form and with a neat yellow eye. The habit of the plant is good, and it is also free flowering. D. B. CRANE.

HARDY CYCLAMENS.

CYCLAMENS are, excepting the Persian one, as hardy as Primroses; but they love the shelter and shade of low bushes or lill copses, where they may nestle and bloom in security. In such places as they naturally inhabit there is usually the friendly shelter of Grasses or branchlets about them, so that the large and handsome leaves are not exposed or torn to pieces by wind or hail. The Ivy-leaved Cyclamen is in full leaf throughout the winter and early spring, and for the sake of the beauty of the leaves alone it is desirable so to place the plants that they may be saved from injury. By acting on these considerations it is easy enough to naturalise the hardier kinds of Cyclamen in many parts of the country. Good drainage is necessary for the successful culture of Cyclamens in the open air. The species grow naturally among broken rocks and stones mixed with vegetable soil, grit, etc., and are therefore not liable to be surrounded by stagnant water. The tuber should in all cases be buried beneath the surface of the earth and not exposed, as in the case of the Persian Cyclamen grown in pots. The chief reason for this is that in some species the roots issue from the upper surface of the tuber only. They enjoy plenty of moisture at the roots at all seasons, and are admirably adapted for the rock garden, enjoying warm, sheltered nooks, partial shade

RAISING FROM SEED.—Hardy Cyclamens are best propagated by seed sown, as soon as it is ripe, in well-drained pots of light soil. Cover the soil after sowing with a little Moss, to insure uniform dampness, and place them in shelter out-of-doors. As soon as the seedlings appear gradually remove the Moss. When the first leaf is fairly developed, they should be transplanted about 1 inch apart into seed pans of rich light earth, and encouraged to grow as long as possible, being sheltered in a cold-frame, but always allowed abundance of air. When the leaves have perished in the following summer, the tubers may be planted out or potted, according to their strength. The following are the more important species and varieties:—

C. ATRINSE.—A hybrid variety of the *Comm* section. The flowers are larger than in the type, varying in colour from deep red to pure white, and are plentiful in winter.

ROUND-LEAVED CYCLAMEN (C. Coum).—This is frequently in bloom in the open ground before the Snowdrop; yet, to preserve the flowers from unfavourable weather, the plants will be better for slight protection, or in a pit or frame planted out. Grown in this way during the early spring, from January to the middle of March, they are one sheet of bloom. Every year, soon after the leaves die down, take off the surface soil as far as the tops of the tubers, and top-dress them with loam, well-decayed leaf-mould, and some rotten cow-manure, well mixed together, or in alternate years give them only a surface dressing of well-decayed leaves or cow-manure. During summer, or, indeed, after April, the glass should be removed, and they ought to be lightly shaded with Larch Fir boughs (cut before the leaves expand), laid over them, to shelter from the extreme heat of the sun. As soon as they begin to appear in the autumn, gradually take these off. Do not use the glass until severe weather sets in—at all times, both day and night, admitting air at back and front—and in fine weather draw the lights off, remembering that the plants are hardy, and are soon injured if kept too close. They do not like frequent removal. There is a pretty white variety of *C. Coum* known as *C. hylemide*.

C. CYPRINA (syn. C. neapolitanum).—This well-defined species has rather small heart-shaped leaves of dark green, mottled on the upper surface with bluish-grey, and of a deep purple beneath. The flowers, which are pure white, tinted with soft lilac (the mouth being spotted with carmine-purple), are well elevated above the foliage. This distinguishes it from most of its allies, except *C. persicum*, and its foliage distinguishes it from that at a glance. It is one of the most beautiful of the hardy

Cyclamen cyprum (syn. *C. neapolitanum*).

and shelter from dry, cutting winds. An eastern or south-eastern aspect is best, always provided there is partial shade. We have seen them growing under trees among Grass, where they flowered profusely without attention.

kinds. It is found on shaded rocks in mountainous districts in Cyprus and other places in South Europe.

EUROPEAN CYCLAMEN (C. europeum).—The leaves of this species appear before and with

the flowers, and remain during the greater part of the year. The flowers are a reddish-purple. *C. europæum* thrives freely in light, loamy, well-drained soil. Where it does badly in ordinary soil it should be tried in a deep bed of light loam, mingled with pieces of broken stone. In all cases it is best to cover the ground with Cocoa-nut-fibre. It luxuriates in the debris of old walls and on the mountain side, with a very sparing quantity of vegetable earth to grow in.

Ivy-leaved Cyclamen (*C. hederifolium*).—Switzerland, South Europe, and the north coast of Africa. Tuber not unfrequently 1 foot in diameter, and covered with a brownish rough rind, which cracks irregularly so as to form little scales. The root-fibres emerge from the whole of the upper surface of the tuber, but principally from the rim; few or none issue from the lower surface. The leaves and flowers generally spring direct from the tuber without any stem. At first they spread horizontally, but ultimately become erect. The leaves are variously marked; the greater portion appears after the flowers. The flowers continue from the end of August until October, and are purplish-red, frequently with a stripe of lighter colour. There are a pure-white variety, and also a white one with pink base or mouth of corolla; these reproduce themselves tolerably true from seed. Strong tubers will produce 200 to 300 flowers. Some are delightfully fragrant. They are quite hardy, but are worthy of a little protection to preserve the late blooms, which often continue to spring up till the end of the year. This species is so perfectly hardy as to make it very desirable for the rock garden and the open borders. It will grow in almost any soil and situation, though best in a well-drained rich border or rock garden, which it well deserves. It does not like frequent removal. It would be peculiarly attractive in a semi-wild state in pleasure-grounds and by wood walks. *C. graecum* is a very near ally, and requires the same treatment. It is much larger in all parts than *C. hederifolium*, but otherwise is very nearly allied.

Iberian Cyclamen (*C. ibericum*).—Belongs to the *Coum* section. There is some obscurity respecting the authority for the species and its native country. It blooms in spring, the flowers varying from deep red-purple to rose, lilac, and white, with intensely dark mouth; and are more abundant than those of *C. Coum*.

Spring Cyclamen (*C. vernum*).—The leaves rise before the flowers in spring; they are generally more or less white on the upper surface, and are often purplish beneath. This likes a light soil, in a rather shady nook sheltered from winds, its fleshy leaves being soon injured. The tubers should be planted deep, say, not less than 2 inches to 2½ inches below the surface. *C. vernum* is considered by many as only a variety of *Coum*. There is a white flowered variety.

NOTES AND REPLIES.

Begonias.—These are surely very fluky things. In a long excursion round the London parks we were surprised to see how bad they were in colour and shabby in effect. For anything so inconstant, and so much depending on what never really comes to us—that is to say, moist, and at the same time beautiful weather—we think they get a very undue place in our gardens, and that many neglected things are more deserving of attention.

Lychnis Haageana.—In the great "lull" that happens between the passing of the summer flowers and the splendours of the autumn Roses and other beautiful early autumnal effects out-of-doors, there are few plants that help better than this with its splendid colour. Its only defect, if such it be, is that it is not perennial, and must be raised every year. I know nothing more worthy of that or any other attention we may give it, if we seek good effect in July and August.—B.

Increasing Dahlias.—In the issue of August 2, p. 303, I see that cuttings of Dahlias can be obtained. I would feel greatly obliged if you would, through the medium of your correspondence column, let me know how this is done? As I have some fine Dahlias, I would be glad of this information.—DALLIA.

[Lift the old roots when the tops have been cut down by frost, and store them away in a frost proof cellar during the winter. Next spring put the roots into heat when you

growths will soon form. These make good cuttings, and soon root if put singly into small pots plunged in heat. When well rooted shift into larger pots as may be necessary, and plant out in May.]

Perennials for garden.—May I again trouble you with some requests in your valuable paper? I have removed to Staplehurst from Ashford, and have a lovely garden, with big lawn and a banked border all round it; but it is a very heavy soil of clay. Of course, annuals are not happy in it. At the top of the borders there are perennials. Would you advise me to have more of them and what? I have Phloxes, Day Lilies, Canterbury Bells, Larkspurs, and Irises. *Nasturtiums* are doing well as an edging. I have also *Geraniums* dotted here and there, which are doing well, only there are still blank spaces.—A. E. S.

[You do not say at what season you would prefer these to flower. Suitable plants for a strong soil are: Christmas and Lenten Roses, Tritomas, Peonies, Flag Irises, Hepaticas, Gaillardias, Michaelmas Daisies in variety, Sunflowers, Hollyhocks, Perennial Pea, Pyrethrum, *Helenium pumilum*, *H. autumnale*, Rudbeckia Newmanii, etc. These, save the Hollyhocks and Gaillardias, are best obtained in plants in early autumn, while the Hollyhock and Gaillardia-seed may be sown at once. Usually, in strong soils, *Campanula persicifolia* in variety is a success, and so, too, *C. grandis*, *C. lactiflora*, etc. You should also try the hybrid *Colombines* that come freely from fresh seeds. You have not given us the size of the border, or the positions where the blanks occur, so we are unable to reply in more definite terms.]

White Lilies in cottage gardens.—We all know too well the failures of white Lilies in gardens generally. I have lately been seeing some very good ones in cottage gardens, which may, perhaps, give a hint as to their treatment. I notice the best on the shady side of the houses, and if that is done, exposure to the sun in cold nights may have something to do with the poor results we often get from these Lilies. I have never been in a country where the white Lilies grow, but I have noticed that other kinds of Lilies are very often wood plants, which means that they get a certain amount of shelter and shade from the trees above. These good cottage garden Lilies that I saw were growing on the surface of the ground in some fine clumps; the bulbs had risen two inches above the level. It may be that we sometimes plant too deep. Many of your readers have had as good an opportunity of observation as I have, and, perhaps, may be able to throw light on this question. We all deplore the malady of the white Lily.—B. V.

Dwarf Phloxes.—I will feel obliged by being informed what is a good selection of dwarf Phloxes, the time for sowing or planting so as to bloom next season, and how I can secure a long succession of blooms? Is it best to sow seed or get plants?—P. B. S.

[If we exclude the early Phloxes, by which we mean *P. suffruticosa* and its varieties, there are really very few naturally dwarf Phloxes. These plants are dwarf by reason of age and treatment only. For example, Phlox Mrs. E. H. Jenkins, one of the finest of the pure white kinds that we have, flowered finely at 18 inches high when only six months old from the cutting. But at four years old the same kind will produce grand heads of white bloom, on stems from 4 feet to 5 feet high, with special treatment. Again, these Phloxes add inches to their stature, and endless pips or blossoms to a naturally fine head of bloom, in proportion to the amount of moisture applied to or reaching the roots. Phloxes are not only gross feeders, but great lovers of moisture, and in these two particulars are rarely everdone. We cannot recommend you to try seed of these, as it is uncertain whether seedlings may appear in three months or three years, or not at all. Plants in pots may be put in now, or in October from open ground, with every hope of a good flowering next year. A deep and rich soil is very necessary for the plants. The following are among the dwarf kinds: Edith, white, purple eye; Coccinea, fine red; Etna, dazzling red; Cocquelicot, vermilion-orange, a superbly coloured kind; Ball of Fire, rich red; Mrs. E. H. Jenkins, pure white; Independence, white; Mrs. J. Hinnett, rose; Mignon, lilac-rose; Oriental, salmon; Bouquet, pink; Pantheon, cerise-salmon; Faust, white and pale pink; Geant des Batailles, white, crimson eye; Aurore, orange-scarlet; Sylphide, pure white; Le Mal di, purple-violet; and Sen-

tris, royal purple. The season of flowering may be extended by rooting cuttings in spring, and planting as soon as rooted sufficiently on a north border to flower; and, secondly, by rooting a later batch of cuttings and growing the plants in pots, as described recently in these columns.]

Raising seeds in boxes.—Everyone is acquainted with the disappointments that often attend raising seedling plants in open-air beds, even when the spring is genial and the seed vegetates freely. Slugs, grubs, or fly some-times make sad havoc, much of which may be obviated by sowing such as must be sown early in boxes, and the sowing of main crop seeds and late sorts may be deferred until more genial weather enables the young seedlings to push rapidly into leaf and beyond the most critical stage of their existence. It is just when in the seed leaf that they are so set upon by insect pests; when fairly in the rough leaf they are comparatively safe. A box to contain enough plants of Lettuce, Cauliflower, and other tender vegetables that it is desirable to get as early as possible need not be very large, and the same remark applies in the case of flower seeds. If there is not room for such boxes under glass, the young plants may be helped considerably if a sheet of glass is laid over the box, only filling the latter in that case half full of soil, and by elevating it on bricks the young plants will be more out of the reach of slugs and similar pests.

Sweet Peas making tall growth.—Mine are doing remarkably well this year, although they came into flower some weeks later than usual. The earliest batch of plants is quite 7 feet high, and they are developing blossoms of the very best. Only in one or two instances does there appear to be a want of robustness in the constitution, and this is more noticeable in the pretty striped variety America and the new brightly-coloured Coccinea. I have never known the Sweet Peas to grow away so freely at this advanced period. There appears to be little or no evidence of deterioration either in the growth of the plants or their individual sprays of blossoms, and there is a prospect of a long continued display. The flower-stalks in several instances have been at least a foot in length, and these, too, of a stout, erect character. The blooms, too, have been, and are still, exceptionally large and of superb colour, the erect standards of some sorts possessing remarkable substance. These facts prove that good culture will always leave its impress upon the flowers and justify one in providing a liberal supply of plant food in the way of deep culture and liberal manuring, and in the warmer weather copious supplies of clear water, followed later by an equally copious supply of liquid-manure.—W. V. T.

Clematises.—Clematises sometimes turn out failures after being planted in the garden for a time, through their being put into worn-out soil or, at any rate, soil devoid of much nutriment. No climbers need a richer compost or are deserving of more attention than these, as they yield their clusters of blossoms with a prodigality surpassing nearly all others. The convenience of purchasing them in pots in bloom has, I apprehend in not a few instances, given rise to mistaken ideas with regard to them, some who buy them at this time of the year assuming, perhaps not unnaturally, that if they can be bloomed in small pots with but little soil, they need but little material when planted out in the open. This will account for many plants, not merely Clematises, but other climbers, when set out against walls doing badly, for, as a rule, the soil is sparse and far from being the best. Walls are most convenient for them to climb over, and there is no better place when the ground is properly prepared. The bed should first of all be well drained, then filling up 2 feet or 3 feet with good turf soil or old dung. In this they will thrive and do well. Clematises make excellent pillar plants in the garden, and being of quick growth soon cover a structure. They will be benefited with manure-water twice a week, and, being gross feeders, one may continue with it up to the time of the buds forming. Treat Clematises generously and few flowering climbers are more beautiful in a garden or over a house-front.—TOWNSMAN.

TREES AND SHRUBS.

HYDRANGEAS IN REGENT'S PARK.

Visitors to the south-west of England cannot fail to appreciate the fine effects of the Hydrangeas that are to be seen in such profusion, and many are envious of the favoured conditions under which they flourish in that salubrious climate. The accompanying illustration represents the outcome of a visit to some of the gardens in South Devon and Cornwall. It shows the value of this plant for rather large decorative purposes in other gardens where it cannot be planted permanently in the open air. It is one of the easiest subjects to deal with. For our purpose, in the London district, it is grown in large pots of from 18 inches to 24 inches in diameter. The plants are protected from damp and frost in winter, they are grown in a greenhouse in spring, and may be moved to the open garden as soon as danger from frost is past, about the end of May. The

pink blossoms, but after transplanting to the woods the blue colouring appears with the first flowers. C. JORDAN, *Regent's Park.*

GENISTA (ROCK BROOMS).

THESE are dwarf and very often tufted in growth, yellow in flower, and of some beauty. They are easily grown and raised, and, being good in habit, should be worth attention in those sandy places where the true alpine flowers are despaired of. They would go well with the Rock Roses, Heaths, and Rosemary, which might be grown in such places. From the following selection we omit those that are too large for the rock garden, or that have been found to be tender in the neighbourhood of London.

G. ANGELICA (Heather Whin) is a dwarf spiny shrub, not often growing to a height of 2 feet. It is widely distributed throughout Western Europe, and in Britain occurs on moist moors from Ross southwards. The short leafy racemes of yellow flowers appear in May and June.

G. HISPANICA, a native of South-western Europe, is a compact undershrub, evergreen from the colour of its shoots. It scarcely attains more than 1 foot or 18 inches in height, and the crowded racemes of yellow flowers are borne at the tips of the spiny twigs from May onwards.

G. HORRIDA (Pincushion Rock Broom).—A very curious close-growing spiny plant with yellow flowers closely set and big as a ball of Moss. Seems of easy culture on open, sunny places, and the poorer the soil the better. Height 10 inches to 14 inches.

G. PILOSA, a widely distributed European species, is a dense, prostrate bush and a delightful rock-garden plant. In Britain it is rare and local, being confined to gravelly heaths in the south and south-west of England. It grows freely, flowering in May and June. Like the rest of the British species of the genus, it has bright yellow blossoms.

G. PRAECOX is a garden name for *Cytisus praecox*, a beautiful hybrid between the white

Hydrangeas in Regent's Park. From a photograph by G. A. Champlin.

plants bear from one to two hundred heads of bloom: these are not of large size, which is not desirable, for they last longer and do not wither so readily when of moderate size. A liberal supply of liquid manure is required to support so many flowers, which are not only showy when fresh, but continue satisfactory as their colour deepens for a considerable time afterwards. The plants are arranged on the grass, with a shrubbery for background, the pots are plunged to half their depth in the ground, the turf being relaid around them. Enormous numbers of Hydrangeas are grown in some of the best Cornish gardens. At Menabilly, Mr. J. Rasleigh's beautiful place near Fowey, there are probably twenty thousand in the plantations near the mansion, bordering the carriage drives and walks, and Mr. Rasleigh is still planting about two hundred additional each year. In regard to colour, the greater number of blooms are blue of varying shades to the deepest azure. Mr. Rasleigh selects cuttings from plants of deep blue, these being inserted for convenience in the open borders of the kitchen garden; in this cultivated ground they invariably produce

G. ASPALATHOIDES, a native of South-western Europe, makes a densely branched, compact, spiny bush from 1 foot to 2 feet in height. It flowers in July and August (the yellow blossoms are somewhat smaller than those of *G. angelica*) and is a good shrub for the rock-garden.

G. ANNANTICA, found wild in the neighbourhood of Naples, is very nearly allied to our native Dyer's Greenweed (*G. tinctoria*). It is very dwarf in habit, and its many racemes of golden-yellow flowers come in late summer. A desirable and beautiful rock-garden plant.

G. EPIHEDROIDES, a native of Sardinia, etc., is a much-branched shrub 2 feet in height, bearing yellow flowers from June to August. The aspect of the plant much resembles that of *Ephedra distachya*.

G. GERMANICA, a species widely distributed throughout Europe, makes a bright rock-garden shrub not more than a couple of feet in height. It flowers very freely during the summer and autumn months, and the stems are inclined to arch when 1 foot or more high. It is sometimes met with under the name of Spanish Broom.

Spanish Broom (*Cytisus albus*) and *C. purgans*, a golden-flowered species.

G. RADIATA, a native of Central and Southern Europe, is 3 feet or 4 feet in height, evergreen from the colour of its much-branched spiny twigs. The heads of bright yellow flowers appear throughout the summer months. It is hardy, at any rate, in the south of England.

G. RAMOSISSIMA.—A native of Southern Spain, and one of the best garden plants in the genus. It grows about 3 feet high, and the slender twigs are laden in July with bright yellow flowers. This also passes under the name of *G. cinerea*.

G. SAGITTALIS (Winged Genista).—A singular plant, its branchlets winged (by the stem expanding into two or three green membranes), and bearing rich yellow flowers in summer; the shoots are usually prostrate, and the plant is rarely more than 6 inches high. It is met with in the Grass in the mountain pastures of many parts of Europe. In cultivation it is a valuable plant, hardy and vigorous in the wettest and coldest soil, forming profusely-flowering tufts when fully exposed. Easily raised from seed.

G. TINCTORIA (Dyer's Greenweed).—A dwarf native shrub, with numerous slender branches, forming compact tufts from a foot to a foot and a half high, and becoming quite a mass of pretty yellow flowers in early summer. It is grown in many of our nurseries, and merits a place among rock-shrubs. There is a double variety. Not unfrequent in many parts of England, but rare in Scotland and Ireland.

G. TINCTORIA VAR. ELATOR is a tall-growing form from the Caucasus, which under cultivation frequently grows from 4 feet to 5 feet high, and bears huge paniculate inflorescences.

G. VIRGATA.—A native of Madeira and one of the most beautiful species of the genus. At Kew there are many old plants from 6 feet to 10 feet high, and as much through, which in July are one mass of colour, every one of the slender branchlets terminating in an upright raceme of golden-yellow blossoms. These plants must be twenty or thirty years or more old, and must have passed through winters which injured many of our native shrubs and trees. Sometimes *G. virgata* flowers a second time in October, but never so profusely as in July.

CHRYSANTHEMUMS.

SEASONABLE NOTES.

This is a critical period in the growth of this plant, as in most cases now what is termed the natural "break" occurs, and if a sharp look out is not kept for earwigs, greenfly, etc., they will do irreparable damage to the embryo buds. The injury thus inflicted is never got over, the result being in the end poor, imperfect blooms. This is most disappointing to the cultivator, especially if he be an exhibitor, as he has no other lateral growths to fall back on, as in the case of the grower for decoration only. The plants will be benefited now with a little weak soot-water, given once a fortnight, and afterwards with guano, a handful being mixed in each canful when watering. The earliest batch should now have the buds set and may be fed a little once a week, discontinuing same gradually as flowers show colour. I refer to plants of *La Vierge*, *Madame Desgrange*, *G. Wermig*, *Mrs. Hawkins*, *G. Glenny*, etc. These make most beautiful plants for the embellishment of the conservatory, and require no stakes of any kind, which I think is a great advantage. Now that autumn is approaching, and rains more frequent, tying as growth proceeds must be attended to. D. G. McE.

B. C. W., N.B.

NOTES AND REPLIES.

Chrysanthemums planted out.—The rage for monster blooms has cooled down considerably, for owners of gardens find that they are about the most expensive of all flowers to produce, and market growers are compelled to adopt the planting-out system. With care in pinching, lifting in good time, and slight disbudding, beautiful plants can be produced with one quarter the labour required for plants grown wholly in pots.—J. GROOM, Gosport.

Early-flowering Chrysanthemums.—The boisterous weather of Saturday and Sunday, July 26th and 27th last, has left its mark upon the early-flowering Chrysanthemums. The moister weather of the present summer season had caused these plants to make very free growth, and, in consequence, the heavy branching growths of many of the best sorts were broken down by the tremendous force of the gale. Fortunately, in some collections, the growers had taken the precaution to stake their plants, and also to securely loop the brittle shoots to the stakes. In such instances the loss has been small. The members of the Mme. Masse family of these plants appeared to suffer more than most others, this being accounted for by reason of the grand branching shoots which they so freely develop. Growers of these plants who have not yet staked and tied their specimens should, therefore, do so without delay. With the approach of August we may expect some boisterous westerly and south-westerly gales, and, for this reason, see that not only the main stems of each plant is safely secured to a stake, but also the heavy branching shoots are securely looped to the stakes.

We make it a rule first to make one knot round the stake, and then loop the branch within another knot, as this gives each stem a certain amount of "play." Keep the soil frequently stirred between the plants. Some of the earlier-blooming plants have already developed their first crop of buds, and, for this reason, it would be well to give them an occasional supply of manure-water.—E. G.

GARDEN PESTS AND FRIENDS.

SILVER LEAF IN PEACHES.

I WAS much interested in reading the remarks on "Silver Leaf" by your correspondent "H. B. J." in your issue of August 2, for in June last I had the pleasure of hearing Professor Percival, of the South-Eastern College, Wye, read a most interesting paper on this disease before the Linnean Society. For many years various persons have investigated this complaint, but with no success. Professor Percival showed most conclusively that it is caused by the attack of a fungus, *Stereum hirsutum*. It appears that the peculiar grey colour is caused by certain spaces between the cells of the leaf just below the cuticle which are filled with air, and not to any changes in the colouring matter of the leaves. How these spaces are formed is at present unknown. It appears that if a branch that is badly attacked be cut across it will be found that the central part of the wood is discoloured, and in mild attacks, even when nothing can be seen by the naked eye, by examination with a microscope it will be found that the cells are stained with a brown colour. Many trees were examined, and in every case it was found that the above-mentioned fungus was present on the roots or root stocks. This, however, was not conclusive that the fungus was the cause of the "silver leaf." In March this year Professor Percival inoculated some healthy trees with the fungus "on one and two year old branches, from 18 inches to 2 feet from the ends. In the first week in May, that is eight or nine weeks after inoculation, the leaves upon these branches exhibited the characteristic silvery appearance." This conclusively proved that the fungus was the cause of the disease. It was interesting to find "that while the disease showed itself above the wound right to the top of the shoot, below the wound it only appeared on the leaves of the next bud or spur, 2 inches or 3 inches away. Moreover, the disease has only appeared hitherto (May 19) on those leaves developed from buds which are placed on the same side of the shoot as that on which the inoculation was made, the leaves from buds off the straight line drawn from the wound to the tip of the shoot being normal. From these experiments and other observations on the course of the disease it would appear that the disturbing cause is conducted rapidly in the sap of the plant." At first sight the views propounded by "H. B. J." and Professor Percival do not seem to agree, but on consideration they are not opposed to one another. For though the direct cause of the complaint is not as "H. B. J." suggests, "weakness through over cropping," it is highly probable that it is owing to some weakness in the tree which enables the fungus to infest it, and such treatment as will restore it to its original vigour prevents the fungus from living on its tissues by restoring them to a perfectly healthy condition. G. S. S.

NOTES AND REPLIES.

Caterpillars.—I send several caterpillars in a tin box, and hope they will arrive safely. They may be very common, but will be glad to know what they are?—M. STAINSON.

[The caterpillars are those of the "Cinnabar moth" (*Euchelia jacobaeae*), a common insect. The caterpillars generally feed on Ragwort or Groundsel. The moth measures about 1½ inches across the wings when they are spread open. The forewings are of a smoky grey colour with a narrow red line near the front margin, and two red spots on the end margin. The hind wings are red with a blackish edge.—G. S. S.]

Insects on Roses.—I will be much obliged if you can tell me what the insect in enclosed box is and how it can be destroyed? It has ruined my *Crimson Rambler*

this year and also attacked the pink *China Rose*, since all the leaves, etc., and preventing them from making any good growth. It is found on the leaves as a grub (enclosed) and the insect.—M. A. M. K.

[The insects you enclosed are not the culprits which have injured your Roses. One of them (the long, spotted one) is the grub of one of the ladybirds, the other is the chrysalis of one of the hoverer flies, whose grubs are most useful in destroying green-fly. These grubs are long and narrow, and are about ½ inch in length. They are bluntly rounded off at the tail, gradually tapering to the head, which is pointed. They have no real legs. The number of aphides they will destroy in a short time is marvellous. I have watched one suck out the contents of a full-grown green-fly in a minute and a half, and immediately begin on another, which it despatched at the same rate, and continued feeding in this way for some time. When full grown they become chrysalides, which are small Pear-shaped bodies about three-tenths of an inch long. The ladybird grubs are quite as voracious, and, being able to move about more rapidly than the other grubs, are perhaps even more useful. The Rose-leaf you sent was covered with the dead bodies of green-flies, which had evidently been killed by the grubs. What may have eaten the leaves I cannot say, but it is quite certain that the grubs which I have mentioned, and which were the only ones I could find, did not. G. S. S.]

Insect on Apple-tree.—The enclosed insect was just taken out of a young Apple-tree. It was about the middle of the fruit. I find some of my young trees infested with a small insect, which is white. I am the trees a winter dressing of caustic soda, etc. You kindly tell me what to use as a dressing for them. You tell me the name of the maggot?—A. CONYER, Bland.

[The insects you find in the wood of your Apple-trees are the caterpillars of the Wood Leopard-moth (*Zeuzera aesculi*). You can destroy them by pushing a sharp-pointed wire into the hole and stalling the insect, or they may sometimes be pulled out by means of a wire with the end formed into a hook. If they cannot be reached in this way they may be stifled by pushing as far as possible into the hole a plug of tow or cotton wool, soaked in turpentine or paraffin oil. The mouth of the hole should then be closed by means of some well-tempered clay, so as to keep the snail in. The moths may sometimes be caught on the trees. They are very handsome insects, with bodies about 1½ inches long, banded with black and white, the wings when spread open measuring about 3½ inches across. They are white with black spots, and are nearly transparent. As to the white insect you mention, I cannot say anything about it without seeing it. Please send a sample.—G. S. S.]

Winter moth in Hornbeam-hedge.—A Hornbeam-hedge in my garden, about 10 feet high, has for several years been spoilt by winter moth, and this year was completely stripped. Is it possible to get rid of it by the system of butter paper described in your paper a few weeks ago, or should it be cut down? I am very unwilling to part with its shelter in a bleak situation, but something must be done, as the pest is spreading to the trees.—L. B.

[I do not think that it would be possible to apply the greasy hand system of destroying the winter moth to a hedge so as to be of much use, as every stem would have to be banded, and all long Grass, etc., thoroughly cleared away, so that there was no chance of the females being able to reach the branches except by passing over the bands. When full grown the caterpillars let themselves down to the ground by a thread, bury themselves in the ground and become chrysalides. If the soil on to which they are likely to have fallen was removed to a depth of 3 inches and burnt or buried a foot or more so that the moths would be unable to emerge from the soil next spring, I believe you would not have much trouble with the pest next year. If the caterpillars again made their appearance, as soon as they were noticed the hedge should be sprayed with Paris green or paraffin emulsion. I would not cut the hedge down.—G. S. S.]

Insects in woodwork.—Please oblige me with names of the wood-boring insect, and, if you can, suggest a remedy? The woodwork of the house and some of the furniture are literally swarming with them. I find them flying in at windows. I have a lot of loam and sawdust, house, etc., faced with Oak top wood. Would this account for their presence?—SARFORS WALTERS.

[The insect attacking the woodwork of your house is *Anobium domesticum*. The beetles belonging to this genus are commonly known

as "Death-watch Beetles," on account of their occasionally making a ticking or tapping noise, which by superstitious persons is supposed to portend a death in the house. The tapping, however, is only a signal to their mates. Any woodwork that they are infesting should be painted or tarred; furniture that cannot be treated in this manner should be well rubbed with furniture polish or turpentine, which should be well rubbed into the little holes; or woodwork may be well washed over with 4 oz. of corrosive sublimate dissolved in a gallon of methylated spirit. This mixture is, however, a deadly poison, and should be used with the greatest care. The beetles lay their eggs on the surface of the wood in the spring or early summer, and it is at this time that the means just mentioned are most effective, as many of the beetles as possible should be destroyed. It is by no means unlikely that they come from the sources you mention. Examine them and see.—O. S. S.]

ORCHIDS.

HARDY LADY'S SLIPPERS.

Amongst terrestrial Orchids the *Cypripediums* are certainly the most beautiful. Their requirements are shade, moisture, and a peaty soil. In all gardens, low-lying, shaly

calcareous soil, or in narrow fissures of limestone rock, in well-drained, rich, fibrous loam, in an east aspect.

C. acaule (Spotted Lady's Slipper).—A handsome kind, seldom seen in gardens, 6 inches to 9 inches high, flowers in summer, solitary, rather small, white, heavily blotched, or spotted with deep rosy-purple. Found in Canada, N. Europe, and N. Asia, in dense forests amongst the roots of trees in moist, black vegetable mould. Requires a half-shady position in leaf-mould, moss, and sand, and should be kept rather dry in winter.

C. japonicum (Japanese Lady's Slipper).—About 1 foot high, its lustrous stems, which are as thick as one's little finger, bearing two plicate fan-shaped bright green leaves, rather jagged round the margins. The flowers are solitary, the sepals of an apple-green tint. The petals, too, are of the same colour, but are dotted with purplish-crimson at the base, the lip large, and curiously folded in front, as in the better known *C. acaule*, to which it seems most nearly allied; the colour of the lip is a soft creamy-yellow, with bold purple dots and lines.

C. macranthum (Large Lady's Slipper).—This bears large flowers of a uniform purplish-rose with deep-coloured veins; early in June—lip finely marked with deep purple reticulations. This handsome and at present rare

NOTES AND REPLIES.

Growing *Laelia superbians* and *Dendrobium suavisissimum*.—Can you give me any information as to how to grow *Laelia superbians* and *Dendrobium suavisissimum*? The former was a newly imported plant last spring, and has made three small bulbs, and it is now only just starting to grow. The latter I fail to do any good with. It makes good bulbs, but never blooms. They are both grown in a house a little shaded, and given plenty of moisture; summer heat, 80 degs. to 90 degs., and 50 degs. in winter. The old bulbs of *Dendrobium suavisissimum* are similar to those of *Caloglyphis cristata*, but a little longer, and some of them appeared to have flowered; but the bulbs that I have grown are similar to those of *Dendrobium thysanotum*. I see both of these varieties are marked intermediate house in Orchid catalogues.—V. B.

[*Laelia superbians* should be grown in the store where the summer temperature is from 70 degs. to 75 degs., and not less than 60 degs. in winter. It should be grown in a basket, so that it may be suspended near the roof, for it requires an abundance of light, sufficient shade being given to prevent scorching of the leaves in the summer. The potting compost should consist of good fibrous peat, leaf-soil, and rough sand, the surface being covered with chopped Sphagnum Moss. The material should be made moderately firm about the roots. Do not dip the plants, but water the surface of the Moss when it becomes dry during the active season of growth. Some grow *L. superbians* in the utility a house, but it rarely flowers satisfactorily when so treated. *Dendrobium suavisissimum* should also be grown in a basket in the above-mentioned temperature from the beginning of March until growth is complete in the autumn. It should then be removed to a cooler and drier position, only sufficient moisture being required to prevent the shrinking of the pseudo bulbs during the resting season. Any repotting required is best done in the spring. It is not advisable to repot more than is absolutely necessary. Afford plenty of light at all seasons of the year, as unless the growths are thoroughly ripened they rarely flower in a satisfactory manner. I consider 50 degs. in winter too low for either of these species; excepting in very cold weather 60 degs. should be the normal temperature of a house for these Orchids. An intermediate house should not fall below 55 degs. in winter in very cold weather.—H. J. C.]

Dendrobium Pierardi

(*Orchid Lovr*).—This fine Dendrobium, which is a common plant in India, is very widely distributed over that country. To grow it well it requires strong heat and abundance of moisture to produce strong growths, which in its native country have been found each 6 feet in length. When fully grown the plant should be dried off and kept considerably cooler than during the summer. This will cause the bulbs to swell up and the leaves to fall. The plant is deciduous, and loses all its leaves before flowering. Early in the season, about April, the flowers will begin to show all along the stems. These, generally borne in pairs, are of a creamy-rose or cream in some forms, the lip large, soft sulphur-yellow, with a few purple streaks at the base. A good compost for it is fibrous peat and Sphagnum Moss. During growth the plants should be given the warmest position possible, at the same time keeping well supplied with water; but during the winter a temperature of from 55 degs. to 60 degs. is ample. There are several forms of this, but the best is *D. P. latifolium*, which bears finer flowers and rather more freely than the type.

Propagating *Clivias*.—Propagation is a simple matter when one has old plants to deal with, as, after they have ceased flowering, the suckers which spring from the base should be severed with a knife and potted off separately in a compost of old loam, finely-sifted leaf-mould, and coarse silver-sand, and if the plants can be placed under a frame in the

The English Lady's Slipper (*Cypripedium Calceolus*) in the Royal Gardens, Kew.

spots can always be found, and, even if not existing, may be readily prepared for these and other plants whose requirements are similar. It should be remembered that this class of plants flowers for the most part in summer, and starting rather late into growth, an opportunity is provided for other things, particularly early and late flowers, without in the least interfering with the plants here dealt with. The following are among the best of these cultivated kinds, and, as a rule, they do well in the positions indicated above:

C. acaule (Stemless Lady's Slipper).—A dwarf species with a naked downy flower-stalk, 8 inches to 12 inches high, flowers large, solitary, purplish with a rosy-purple (rarely white) lip, nearly 2 inches long, which has a singular closed fissure down its whole length in front. Northern States of North America in woods and bogs. Thrives in moist peaty or sandy soil or leaf-mould.

C. calceolus (English Lady's Slipper).—The only British species and the largest flowered of our native Orchids, 1 foot to 1½ feet high, flowers in summer, solitary (sometimes two), of a dark brown colour, with an inflated clear yellow lip netted with darker veins, and about 1 inch in length. North Europe, and occasionally in the northern counties of England, where, however, it is now almost exterminated. Very ornamental for the rock-garden, where it should be planted in sunny sheltered nooks of

plant grows best in pure loam of a heavy nature. Siberia.

C. pubescens.—A dwarf species with a pubescent stem, seldom more than 2 feet high, flowers early in summer, on each stem one to three blooms; greenish-yellow, spotted with brown, with a pale yellow lip from 1½ inch to 2 inches long, and flattened at the sides. It is found in bogs and low woods, from Pennsylvania to Carolina. Does well on dry sunny banks, among hem, stones, and grit.

C. spectabile (Moccasin-flower).—The most beautiful of this group; 15 inches to 2½ feet high, flowers in summer, one or two on each stem (rarely three), large, with inflated, rounded lip, about 1½ inch long, white, with a large blotch of bright rosy-carmine in front. A variety (*C. s. album*) has the lip entirely white. In America it grows in open boggy woods, moist meadows, and also in peaty bogs in the Northern States. Good native specimens produce from fifty to seventy flowers on a single tuft, 3 feet across, formed on a thick mat of fleshy roots. The plant is hardy, and succeeds if planted out in a deep, rich, peaty soil, with a few nodules of sandstone or rough sandstone grit mixed with the soil. It also thrives in turfy loam on a moist bottom; in any case, however, deep planting is necessary, as the roots are then cool and moist during the hot weather, and do not suffer from frost in the winter.

house and kept close for a few weeks, this will help in the formation of roots. After blooming, old plants should be repotted, if found necessary. As window plants, when in flower, Clivias are most acceptable.—TOWNSMAN.

FRUIT.

SOME GOOD PEACHES.

Will you give me the names of four best Peaches and two Nectarines for an amateur to grow under glass in Lancashire, second early and midseason sorts, to ripen in August and September? By best I mean flavour, size, and free bearing, and, as I cannot be home in middle of day to fertilise blossoms, free setting and non-liability to cast flowers and fruit. I see Goshawk is spoken of in catalogues as best flavoured of all. Is this so, and has it any undesirable traits which more than outweigh its excellence in that respect? I do not wish to force, but have plenty of heat, but my disadvantages are (1st) that my greenhouse is shaded part of the day, and so does not get all the sun it ought, and (2nd) not being able to attend to the trees in middle of day. I have a tree, however, of Lord Napier Nectarine which is fruiting and doing very well. Perhaps you could add a few words as to making up of border?—PEACH.

[The variety Goshawk is not usually accredited with possessing the highest quality, though all the same a good Peach, and may be included in a selection of four varieties. Others we would name are Hale's Early, a very good American variety, preceding the ordinary mid-season kinds and a free cropper, Bellegarde, a fine September Peach when not much forced, with Royal George and Dymond. In some gardens Royal George is subject to mildew, and for this reason cannot always be successfully grown. No finer flavoured fruit exists, however, under good culture. Stanwick Elruge, white fleshed, and Pine Apple, yellow fleshed, are two good Nectarines, unsurpassed in their section and season. These are all free setters given reasonable treatment. If your tree of Lord Napier does well there is no reason why others should not do likewise. While in bloom abundance of air is absolutely necessary, and with a little air left on all night the pollen would be dry in the morning, and could be distributed by giving the tree stem a sharp rap with the hand. This would dispose of the necessity for mid-day attention. In the construction of Peach borders it is desirable to provide an under rather than an over-rich soil. What is known as strong calcareous loams are best suited for Peaches, but there is no hard-and-fast rule. Peaches must have lime, either naturally present in or incorporated with the soil, and it is well in any case to provide some. Old lime obtained from demolished buildings is better than new, though if it cannot be procured, now lime must be substituted in less quantity. Be sure, however, in the use of this to mix it well with the soil, or it may, if placed in layers, become injurious to water. Good garden soil, if of a suitable nature, and free from tree-roots, will grow good Peaches, with the addition of some lime, or a little burnt ballast or burn-bake. Animal manure must be avoided in making Peach borders; if any deficiency exists employ some of an artificial compound, and use this in moderation. Make the soil firm by treading or ramming, as this promotes sturdy short-jointed growth. Drainage will depend on the nature of the sub-soil. If of an open character none will be required, if heavy and badly-drained, then employ brick rubble, stones, or clinkers to raise the soil off the saturated base, and provide an outlet for superfluous moisture to escape. In soils of a light or medium nature too much drainage is an evil, for it promotes bud and fruit dropping through drought, which is fostered by it. Plant, if possible, in November, for then the trees may form a few autumn roots, and do not attempt to secure a crop the first year.]

SYRINGING FRUIT TREES.

During the heat of summer it is well-nigh impossible to give growing crops of fruit, whether they be under glass or in the open air, too much water, for if the heat is sufficient they will evaporate through healthy foliage a large amount of it, and great care is necessary in keeping the roots abundantly supplied, for any lack of moisture will cause the foliage to droop under bright sunshine, and then red-spider, and other pests, that are attracted by

drought, come on, and they are not so easily got rid of. One of the first things to fly to when drooping foliage prevails is the syringe, and a good shower bath overhead soon revives the leaves; but this damping should be followed by a thorough soaking of water to the roots, enough to reach the lowest of them before the sun acts on the leaves again, for healthy foliage of fruit-trees ought never to flag under any heat we get in this country if the roots are healthy, and there is enough moisture in the soil for their needs. The following is the plan I adopt with regard to overhead syringing.

VINES.—Syringe the rods with tepid water when the house is started for forcing, as soon as the sun's rays begin to decline, and the house is shut up with a good, brisk heat, and this is continued, on bright days, up to the time the bunches are in flower, when the atmosphere is kept rather drier, merely damping the paths and any dry spaces to create a moist, genial atmosphere. This, also, is continued until the Grapes are ready for thinning; but after this is performed I give the Vines overhead a thorough drenching with the syringe after a bright day, so as to make the leaves quite clean, and thoroughly wash out every small berry, old bloom, etc.; but after this has been repeated two or three times I use the syringe no more. In the place of overhead syringing I use a good deal more water in damping the floors, side-walls, stages, etc.—in fact, every dry spot in the house—and shut up with a good lot of solar heat, and then in half an hour the whole interior of the structure is like a vapour-bath. This is continued until the berries begin to change colour, when a drier atmosphere and more ventilation are necessary to ensure high finish.

PEACHES AND NECTARINES under glass or on open walls are very liable to red-spider, and after the fruit is set a good drenching with the syringe or garden-engine is of the greatest benefit in dislodging green or black-fly and keeping red-spider from getting a footing. Care should be taken to have clean water after the fruit gets half grown, but in the early stages of growth I find a little soft-soap dissolved in the water one of the best of things for promoting clean, healthy growth.

CHERRIES are very liable to the attacks of black-fly, and after the fruit is set the garden-engine or syringe may be vigorously plied on them with good results. Soap-suds diluted with clear water make a good wash, as it is just after the fruit is set that the attacks of fly are most troublesome, and a few copious drenchings then act beneficially in more ways than one, as the abundant blossom of Cherries when the fruit is set needs a good deal of washing to get the fruit cleared of it, but they swell at a great pace, with plenty of washing, and the roots get the benefit of all the water that reaches the soil.

PLUMS are not so much affected by fly as Cherries, but a few thorough good washings to dislodge all half-set fruits and cleanse the foliage of dust is a great help, and if any signs of scale, American blight, etc., appear on the bark of any kind of fruit-tree, ply the syringe freely, and they will be greatly checked, if not entirely cleared off.

WARTS ON VINE-LEAVES.

COMPLAINTS come frequently from those who have not had much experience in Grape culture about the prevalence of warty-like excrescences upon the under sides of the leaves. This is the effect of one of the errors—too much moisture—in the treatment of Vines which amateurs commit. Especially in the case of young Vines is it more noticeable. Vines which have their foliage covered on the under side with warts cannot perfect a crop of Grapes so well as those which have their leaves free of such unnatural excrescences. This defect in growth is the outcome of too much moisture upon the leaves and atmospherically. In the latter form the mischief is most generally committed, although in conjunction with an insufficient supply of fresh air. Amongst cultivators generally it is a rule to damp the surface of the borders, paths, walls, and stages, if there be any inside the house, twice daily, and in some instances oftener. This treatment is all very well when judiciously carried out—that is,

when the days are bright, so that an abundance of air can be admitted to the house without unduly cooling the temperature; but loading the inside of the house with moisture when the outside elements do not admit of sufficient fresh air being admitted causes the formation of the warts. In the case of new vineries, or even old ones, where the Vines have just been planted, many persons make it the rule to thoroughly drench the foliage twice daily during the time growth is active. This treatment may be correct when the weather is hot and the outside atmosphere dry, but when the atmosphere is loaded with moisture, and but little of the sun's power felt, then the daily syringing twice, or even once, is a mistake. Grape-growers who are year after year successful study the appearance of the weather daily before determining the treatment the Vines shall receive for that day, as upon this point depends much of their success. A superabundant quantity of atmospheric moisture inside any vinery must be avoided. Moisture is necessary for the life and success of the Vines in perfecting their crop of fruit, but it should be given in such a manner as to be easily balanced by a judicious supply of fresh air.

The first thing to do when Vine-leaves are affected with warts is to check the supply of moisture in the air by damping down the borders only when the weather is bright, and this but once daily, preferring the afternoons at the time of closing the house. Air should be admitted very early in the morning, when the temperature reaches 70 degs. When the temperature is allowed to rise to 80 degs before any air is given, the air in the house becomes stagnant, and is not conducive to a healthy growth of the Vines. The pores of the leaves become so gorged with an excess of moisture that assimilation is hindered to a certain extent, the result being warty foliage. If the atmosphere outside is loaded with moisture, it is the height of folly to do likewise in the vinery. By equalising the supply of moisture and heat in the vinery—both very necessary matters in Grape culture—Vines affected with warty foliage can be cleared of these excrescences in the future growth. It is not possible, perhaps, to rid the present leaves of the warts when once thoroughly affected, but the after growth can be made perfect by a judicious application of air to the house, aided by the proper regulation of moisture.

NOTES AND REPLIES.

Good Raspberries.—I shall be much obliged if you will kindly give me the names of the best red and yellow Raspberries? I find that so many of the beautiful-looking fruits now sold are tasteless and not fit to eat. C. H. BEXWICK.

—Will you please give me the name or names of two good Raspberries? Soil heavy and rich, clay subsoil.—F. M. G.

[Good Raspberries are—Reds: Superlative, a large and handsome fruit, with an absence of watery juice. We have seen this with canes each 8 feet and 9 feet high. Red Antwerp is an old kind but good. Baumforth's Seedling is large and richly flavoured; and Norwich Wonder, a strong grower with richly flavoured fruit. Yellows: The Guinea, a yellow Superlative, and equally as strong in growth; and Yellow Antwerp, a good old kind.]

Strawberries falling.—I send a specimen of Strawberry-plant, and will thank you for your opinion as to woody growth of roots and poor fibre? The plant has been in ground for three years; the soil is light, about 2 feet to 3 feet, on gravel. The crop has failed this year, and was only partial in 1901. This same ground has been used for Strawberries for some years, but every three years the ground is trenched 2½ feet deep and thoroughly manured. The want of sufficient rain prevents good fall crops.—M. CHALLIS.

[It is not to be wondered at that your Strawberries fail, seeing you grow them on the same ground year after year. Do you use the runners from your own plants also? You ought to try the annual mode of culture, which has been frequently referred to in these pages. In such a soil as yours you ought to water and mulch freely just previous to the fruit ripening. The plants are evidently starved from want of food and moisture.]

Renovating weakly Vines.—I have a vinery with five Vines, which are planted in an outside border and do not touch the wall. They are old Vines and have borne some very heavy crops; but now they only bear an average of four or five bunches each, and are showing a lot of small, watery wood. Do you think I had better

take them up and cut off the tap-roots, and plant them nearer the surface? They are now about 4 feet down and gone into the clay. Do you think I shall get any benefit from it? If so, please say when is the best time to do this?—G. H.

[The weak state of your Vines points to the fact that in former years they were over-cropped, and probably not given sufficient nutriment to sustain their unusual load of fruit by watering and manuring. When Vines are so heavily cropped it takes a surprising quantity of water and stimulant to properly support them. If your Vine roots are, as you say, in the subsoil, at a great depth, your best course is to lift them and arrange them nearer the surface in fresh soil. This may be done at the end of October or in November. Every care should be taken that the roots are kept moist, and preserve as many roots as possible, particularly those of a fibrous nature. A digging fork is the better implement to employ, because this can be used without unduly breaking the roots. If you cannot remake your border entirely, procure as much new soil as you can and incorporate with the old, also lime-rubble, $\frac{1}{2}$ -inch bones, and hurot refuse. In the larger roots make some V-shaped incisions with a sharp knife here and there about $\frac{1}{2}$ inch deep; this will cause new roots to form. It is a good plan to mulch the surface with manure to keep out the sun and air in summer. If the surface is kept constantly dry the roots harrow deeper for moisture, and in this way get into the subsoil, of the results of which you have had ample experience.]

Removing mulching from Strawberries.—Most growers will admit that much of the success of the next year's crop of Strawberries depends on their treatment during the autumn and winter. No hard-and-fast line can be laid down, seeing so much depends on soil, climate, etc. While this is so, errors are often made in their treatment at this season of the year. I am convinced that the early removal of the straw that has been used to keep the fruit clean is one of the greatest. This especially applies where the soil is light and the climate dry. In spring early mulching is recommended to keep in the moisture. Why remove this as soon as the fruit is gathered, seeing the next two months are often the driest in the year? To remove this, exposing the soil to hot, dry sun after the roots have been induced to work near the surface cannot be beneficial to root action, more especially in hot, dry soils. For several seasons I have, as soon as possible after the crop is gathered, had all the runners and any rough or partly dead leaves cut off close to the plants, pulling up all weeds, and moving the mulching so as to make all clean. Everything is left spread over the ground and round the plants, the runners soon drying up. When the hot weather is over, about the end of September, this is removed, and about the end of the year a dressing of dung is given the beds.—J. CROOK.

Peaches and Nectarines.—When the fruit is cleared from the trees in the earliest season they must still be well attended to, or next season may see a partial failure. After syringing ceases, this being when the fruit is on the point of ripening, the borders, previously constantly being moistened and, it may be, trampled on frequently, commence drying, cracking very probably following in due course. Lightly loosening the surface with a fork and mulching with strawy manure are good preventives of this, and if not carried out prior to the crops being gathered should be done immediately after, the mulching in this case following upon a thorough good soaking of water, or, better still, liquid-manure. Newly-moved trees will continue growing after the crops are gathered, and this growth should be fostered by means of morning and evening overhead syringing. Older trees should have much of the wood that has just produced fruit cut out, and if there is any red-spider on them, instead of daily syringing the trees and thereby keeping them growing later than desirable, the better plan is to thoroughly coat both surfaces of the leaves with flowers of sulphur. Squeeze a double handful through a canvas bag into a 3-gallon can of water, and well syringe the trees with this mixture. If the first application does not suffice, repeat the dose. The house should be set widely open and the border

never become very dry. See that the borders supporting the successional trees are in a thoroughly moist state when the fruit commences ripening. Every morning all fruits that are ripe enough to gather without actually dragging them from the trees ought to be collected and stored in a cool, dry room ready for packing or home consumption, the quality and keeping properties being improved by this timely attention. Let ripening fruit have plenty of air.

GARDEN WORK.

Conservatory.—Though watering, shading, and ventilating glass structures may be called routine work, yet it must be intelligently carried out. No work calls for more judgment than watering plants in pots. If more is given than the plant needs, the soil becomes sour and the plant suffers, and if this state of things continues the plant dies and the gardener's reputation suffers. Never water a plant till it is necessary. Do not try to anticipate what the plant's needs may be in a few hours' time. Wait till the plant is thirsty and then moisten all the soil and leave it till it becomes dry. No good plantsman would water a specimen plant till he had tested its condition with his knuckles on the side of the pot. This is the best test. It is true there are niceties of sound to be considered, due to the way in which the plants are potted. A loosely potted plant may sound dry when the waterpot is not urgently needed, but experience soon teaches discrimination, and nowadays the tendency is towards smaller pots and firm potting. The market grower has taught this by the way in which he produces a large plant in a comparatively small-sized pot covered with a profusion of blossoms. No loosely-potted plant will do this. It is impossible to obtain a compact, well-flowered plant with the soil in a loose condition. Good drainage is of the very first importance, and for the drainage to be free the material must be placed in a proper position. This is of more importance than mere quantity or depth. One large crock over the hole in the bottom of the pot, with the hollow side downwards—a flat crock over the hole might act as a check upon the escape of the water, and the plant suffer from an excess of moisture. On the large crock in the bottom a layer a size smaller is placed, and on these, again, a few pieces about the size of small Beans. A few bits of fibrous soil will complete the drainage. For Ferns, Jado or Cocoa-nut-fibre may be used. The depth of drainage will depend upon the size of the pots, and in some measure upon the class of plants grown. The market grower does not worry himself much about drainage, but the plants leave his hands when they come into flower, and the purchaser, as a rule, does not study this matter. Nine-tenths of the plants purchased in a market disappear after flowering. Among the thousands of Azaleas imported annually, how few live over the second season. The same thing occurs in a less degree with other market plants, and some of these failures are due to defective drainage. Arum Lilies, if they remain in pots, must soon be seen to and repotted, dividing the crowns where necessary according to the size of pot required. Arums want a generous soil and free drainage, and after repotting, the plants must have a sunny position on a coal-ash bed, or precautions must be taken to keep out worms in some other way.

Flowers for winter.—These cannot be obtained in the short, dark days without artificial heat, and this is where the stove or forcing-house does its best work. Among the plants which are, or should be, grown in quantity for winter work are Poinsettias, Euphorbias, especially *jacquiniaeflora*, Begonias, to include *Gloire de Lorraine*, and others. The semperflorens type flowers freely in winter, and the same may be said of the insignis family. A group of insignis in the conservatory in the dead of winter is always attractive, and the flowers last well. *B. fuchsoides* is an old one, but is superior as a decorative plant to some of the modern kinds, and it is so distinct and does not require so much heat. I have had it planted out in a light, warm conservatory

where it grew and flowered all winter. The stove produces many flowers in winter, both in climbers, which may be planted out, and others in pots or tubs. The demand for flowers for cutting is enormous, and everything in plant culture has to be looked at from that point of view. *Justicias* are bright, and flower freely, but do not last long in a cut state. A good plant or two of *Jasminum gracillimum* will be very useful. *Ipomœa Horsfalliae* is very bright, but the flowers last only one day, but a fresh supply opens every morning. *Allamandas* are gorgeous, and in a cool stove where they have plenty of room and nourishment they will last well into the winter. Among smaller things are *Centradenas*, *Plumbago rosca*, *Pentas rosea* and *P. alba*, and, of course, there should be many flowering plants of *Eucliaris Lilies*.

Renovating early-forced Vines.—If the roots have got too deep or out of hand, one need not wait much longer to set about their renovation if a good supply of tufty loam can be obtained. Get it chopped up and prepared ready for use. Bone-meal or crushed bones is always valuable in a Vine border, and there are other manures, such as Thomsons', which are exceedingly good for Vines which have been run down by over-cropping, or where the roots have got into bad condition. The work of lifting the roots may be done in September. Cover the roof with something to shade the foliage, as it is important to keep it fresh as long as possible, and use the syringe freely to the same end, and when the work is begun follow it up as briskly as possible till completed and the roots are made comfortable again. The Grape-Vine, when the roots are placed in a good rooting soil, will repair damages with astonishing rapidity.

Strawberries for forcing.—This has not been a good season for obtaining runners, but the difficulty will be best overcome by growing a few rows of young plants especially for runners for forcing, as the plants ought now to be in their fruiting pots, or, at least, ready for shifting on. Good stuff, especially as regards the quality of the loam, is essential, and it should be fortified with bone-meal and a dash of soot, and some suitable mixture of artificials. Stewed bones are quite safe, but chemical manures should be used very carefully. Many good growers use only stable-manure, but I like a little soot and a dash of bone-meal. All fruits seem to like this. The potting must be firm, and space should be left at the top to hold water, and the pots must not be too small for such strong growing sorts as *Royal Sovereign*. Six-inch pots must be used. I expect more *Royal Sovereign* will be forced than any other, but *Leader* has been highly spoken of. Size is a necessity now-a-days, and *Keen's Seedling* and *Hericart de Thury* seem to have dropped out of the running. Stand the plants thinly on coal-ashes or boards to keep out worms, and water carefully and damp the foliage daily. Keep all the runners pinched back. For late forcing, *Sir Charles Napier* is a good kind.

Window gardening.—If any plants of a permanent nature require a larger pot, now is the time to do it. Use clean, well-drained pots, and it is not wise to give very large shifts at this season, though the character of the plant will be considered. Palms, Rubbers, *Aralias*, and other fine foliaged plants may be potted now, and, in a case of emergency, *Azaleas* and *Camellias* may be potted. Very few succeed with these as room or window plants, but *Myrtles* which have been neglected of late years might be brought back to health with advantage.

Outdoor garden.—It is time now to put in cuttings of the usual tender summer-flowering plants. Tuberous *Begonias* are gradually making their way, and where the varieties are well selected they make very bright masses, but the ordinary mixtures are not quite satisfactory. I have seen them used in window-boxes in a satisfactory manner. The *Maiden's Wreath* is a charming thing in a mass in the border, and the long flower-spikes are exceedingly useful for decorative work. *Seedling Petunias* make very bright beds in dry, sunny spots. The size of some of the flowers among seedlings is enormous, but they do not stand the weather so well as the smaller-flowered kinds. Still, there is a demand for these monster

flowers. Single-flowered Hollyhocks are bright and effective, and are certainly making their way in most gardens. The Everlasting Peas are most useful and reliable. They are easily raised from seeds, and though the seedlings vary a little in colour and growth they are all useful. There has been rather a dearth of good border flowers, except such things as Gillardias and Coreopsis, which can always be counted upon. Lemoine's Hybrid Gladioli are showy, and free from disease than other forms, and good muses of the Peruvian Lily (*Alstromeria*) are bright and effective. Sow seeds of Pansies for blooming next spring. Give liquid-manure to all things which require help, and they are numerous this season.

Fruit garden.—There seems to be a general consensus of opinion among growers that "Lealer" is one of the best and most profitable Strawberries to plant, and it is always an advantage to have the best of anything. The tendency of the age is to strive after big things, and in consequence the Alpine Strawberries are neglected, but a bed of Alpines from this onwards will be useful, and if the plants are well nourished the fruit will come a good size. A punnet of Alpines on the table at breakfast will be an aid to digestion. In the matter of ripening wood in fruit-houses, the process will be completed in all early houses. If it is not, a little fire heat may still be used. Exposure to cold, damp air is not so good a ripener as the circulation of warmth. In the matter of Peaches, I have often wished for the movable lights we had in the past, for the sake of the exposure and the moistening of dry spots which had been overlooked in the borders. Trees in pots, of course, may be outside now, but the roots must be kept in a moist condition. This is the time when the buds are maturing, and if the roots are too dry, injury may be done that will show itself next spring in the buds falling. Summer pruning among fruit trees should be continued, and if the weather continues dry a good soaking or two of some quick-acting liquid-manure will be of great help.

Vegetable garden.—Cauliflowers may be sown about the 20th, or the sowing may be deferred a few days, and the seeds sown in a cold frame, or, to be on the safe side, both sowings may be made, and we generally sow a few seeds in heat towards the end of January. Early Erfurt is a good Cauliflower, with Asiatic and Veitch's Autumn Giant for succession. The Early London seems to have lost caste among growers, possibly because it seems more difficult to obtain true than was formerly the case. The same may be said about the Walcheren. Lettuce and Endive should be sown freely now, good hardy kinds being selected. Late-sown Horn Carrots may be thinned a little, but not so much as the spring-sown crop, as the roots will be used young. Keep the hoe going among late-planted Greens, as the plants are not making much growth in consequence of the drying of the ground. Give liquid-manure to Celery and Leeks, and any other crop that appears to require it. Dust a little soot from time to time over Celery to keep off the fly. Sow late Turnips after Potatoes. Spinach and Onions will come right if sown now. Sow all things in drills, and if the weather continues dry, well soak the drills with water. Sow on the damp soil, and cover with the dry soil. E. Hornay.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 18th.—The forwardest Primulus and Cinerarias have been shifted into 5-inch pots, and are on a coal-ash-bed in a frame in a partially shaded position, very freely ventilated. Stable-manure is being collected for making up Mushroom-beds in Mushroom-house. It will be turned and made ready in an open shed till some of the moisture and rankness has been driven off by fermenting. Vines in pots intended for next year's forcing have been placed outside to ripen.

August 19th.—Fero spores from various kinds of Pteris, Cyrtomium, Adiantum, etc., have been sown in pans filled with loam made firm, and well moistened before sowing. The pans will be covered with glass and placed in the

shady pit. They will be kept moist by dipping in a tank when required. It is best to grow one's own spores, taking them from well-grown plants in a well-ventilated house. Earthed up Celery, Sowed Spinach, Turnips, Giant Zittau Onions, and various hardy Lettuces. Gathered vegetables for pickling.

August 20th.—Chrysanthemums are looked over frequently to destroy earwigs and remove surplus growth. Some of the buds are being selected. Liquid-manure is given to plants which require feeding, but discrimination is used. Potted the first batch of Roman Hyacinths. Freesias also have been potted. Gathered seed of various hardy and other plants, of which good seeds could be obtained. Liquid-manure is given to Leeks, Celery, and Cauliflowers.

August 21st.—Made a first sowing of Cauliflowers for spring, as the ground was dry. The seeds were sown in drills, the latter being well moistened, and the seeds sown on the damp soil, covering with dry soil from the sides of the drills. There will probably be rain soon. We do not usually have to water when sown in thoroughly damp soil. It is necessary to pick over flower-beds to keep them in good order once a week or so. Cuttings are being taken.

August 22nd.—The syringe is used freely among Azaleas, Camellias, and other greenhouse plants in the open air in the evening of hot days. The buds of Camellias, where too numerous, have been thinned. All flower-buds are picked from Zonal Geraniums intended for winter flowering which are now in the open air. The watering is carefully done. A water-logged plant seldom does any good.

August 23rd.—Put in cuttings of a few really good Hollyhocks. Single joints are obtained by cutting up the side growths, and are thrust into beds of sandy soil in a close frame. They will be kept moist and lightly shaded when the sun is hot. Ventilation is given in the morning to prevent damping. The cuttings soon form roots, and are potted up and wintered in pots. Liquid-manure is given to Roses, Asters, Phloxes, Dahlias, and Hollyhocks. A few good specimen plants have been taken to conservatory, including Bougainvilleas, Plumagos, etc.

BEES.

SEASONABLE WORK IN THE APIARY.

EVERYONE in the Heather districts, very little surplus honey is stored after the end of July. Supers should therefore be removed without delay, for if left on the hive for any length of time after the cessation of the honey flow, the contents are likely to be removed by the Bees and stored in the hive. After the removal of the supers the hive should be closed up, and draughts excluded, to encourage the rearing of brood, as colonies possessing abundance of brood in August remain strong and populous during the winter and spring. Such colonies are ready for work early in the following season, while weak stocks lose much valuable time in having to rear large numbers of young Bees in the spring. Stocks strengthened at the end of the honey season by having Bees of driven hives joined to them, are of far greater value than those receiving no addition. They are better able to stand the severities of the winter, their first swarm in good seasons filling the hive with stores and brood before colonies not so strengthened in the autumn have made preparation for swarming. In the case of straw hives heavy with honey, it answers very well to remove the Bees by the process of driving, putting two or three lots of driven Bees together in one hive, and liberally feeding them on sugar syrup. If a sufficient quantity of sugar syrup be supplied—and about 30 lb. should be given, as much is used in the elaboration of wax for the construction of the combs—stocks so formed always prove profitable in the following season. It is well, however, to remember that combs made from sugar syrup are more brittle and more easily broken than those made in the natural way. If it be preferred, the driven Bees can be united to colonies that are to be kept through the winter. This is a great saving of labour to the Bees, as, of course, in this case there is no comb-

building to be performed. The hive to be driven should, after having had a little smoke puffed into the entrance, be gently removed from its stand and inverted, and, if round-topped, should be placed in a pail or pan to keep it steady. An empty skep should then be placed over it, mouth to mouth, and a cloth tied round the junction to prevent the escape of any of the Bees in their upward march into the empty skep. The sides of the tall hive should then be rapped with the open hands sufficiently hard to jar the comb; in a few minutes the Bees will be heard rushing up with a loud hum, and, the rapping being continued to keep them on the move, they will shortly be found to have left their old hive and clustered in the top one, which can then be removed and placed upon its old stand to receive any flying Bees belonging to the colony.

The reason for injecting a little smoke into the entrance of the hive to be operated upon is that the Bees thereby become alarmed and partake freely of their honey as at swarming time, and in this gorged condition they seldom sting, and consequently are the more easy to manipulate. The smoke from smouldering touch-wood, brown paper, or fustian is the best for this purpose, and should be used in a bellows smoker. When it is wished to see or capture the queen the empty skep is fixed up like an open lid by means of a skewer and driving-irons (which are pieces of stout wire turned at the ends and pointed), the algs of the hives being brought together at the point towards which the combs run. Should a time become queenless no time must be lost in uniting the Bees to a colony possessing a fertile queen. It can be done in the case of frame-hives by quietly inserting the combs, with adhering Bees, on the outsides of each colony. This should be done in the evening, after a little smoke has been injected, and the united Bees fed with a little syrup. The loss of a queen can generally be discovered by the incessant agitation of the inmates of the hive which crowd at the entrance and run about over the floor-board as if in search of something, this being continued after the Bees of other hives have settled down for the night. A queenless stock can also be saved by introducing into the hive a fertile queen. A queen-cell containing a young queen, or a frame of comb containing eggs or brood, will prove effectual early in the season. In queen introduction a queen-cage is sometimes used; in this the queen is confined when first placed in the hive lest the Bees should destroy her. By being placed between the combs for a time in the cage and then set at liberty, she is generally well received by the queenless colony.

S. S. G.

LAW AND CUSTOM.

A gardener's perquisites.—My gardener was engaged at 25s. per week, with conditional contract of four apartments and 5 tons of coals found yearly. When engaging him I distinctly mentioned that I allowed "no perquisites." Still, he argues that he is entitled to vegetables for himself, his wife, and family of six, these taken by his own hand at his own discretion, and not from me or my cook as we can spare them. Is it recognised that gardeners have all the vegetables they can use, or do vegetables come under the head of "perquisites"? A clear reply to the above will much oblige.—F. W. M.

[There is no rule of law or custom which allows a gardener to take for his own use and for the use of his family such vegetables as for that matter any vegetables as he chooses. Such, if taken by permission, would certainly be perquisites, and as you expressly stipulated that no perquisites would be allowed, it is clear that the man cannot claim vegetables as of right. This answer is written in the hope that it is sufficiently clear, but I must warn you that I profess no knowledge of Scotch law.—K. C. T.]

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1. Mr. Geo. H. Towndrow, Kennetholme, Mulvera Link, for Rose on an old corrugated iron shed. 2. Mrs. Readman, Myrtle Park, Hereford, for wall fruit-trees in bloom.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Furnival-street, Holborn, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind really assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only taken in those directions are observed.

PLANTS AND FLOWERS.

Tradescantia zebrina (V.).—This plant requires a average winter temperature of not less than 50 degs. F., is, when not thriving well in a cool greenhouse, but among one of the best of window plants for a warm room. It should be grown in a basket or the pot should be suspended, the shoots then drooping down from a dense centre of beautifully marked foliage. A rather light, sandy rich loamy compost should be used, and good drainage should be provided, as abundance of water at the roots is needed in the summer.

Crimson-flowered Flax (Linum grandiflorum).—This is a fine showy annual which may be had in bloom from May to October by means of successive plantings. Seed sown in autumn will produce plants for spring blooming, and sowings made from March till May will yield a display in the summer and autumn. It is best sown in good rich soil, and plunged in a hot border with plenty of water, plants may be raised for the greenhouse or window during October, and November. The flowers are of a glowing crimson blue.

Dahlias failing (Portland).—Your plants are being left by earwigs, which are very partial to Dahlias. The best way of destroying them is by trapping them, or, as they are night feeders, by catching them after dark. The best traps are the hollow stems of Sunflowers or Broad Beans, from which they may be blown into a pail of boiling water. Small garden pots filled with Moss and placed in the top of stakes also form good traps. In fact, anything in which the earwig can hide during the day is useful. Gather the lavender when in full bloom, and dry it well in an airy place.

Propagating Cytisus racemosus from cuttings (B.).—This is not one of the easiest of hard-wooded plants to propagate, the cuttings often remaining for a long time before making roots. The best time to take the cuttings is when the plants are in free growth before the hot weather sets in. Cut them to three joints, and insert them in a light, well-sanded compost, planting in pots in a cold-frame, keeping them close, and shading the plants in a greenhouse, and do not allow the soil to become dry, and by the spring some will have taken root, all these can be potted off singly.

Diseased Hollyhocks (M.).—The plants are infected with the Hollyhock fungus (Fusicladium malvarum). As a rule, the best plan in such cases is to pull up the affected plants and burn them. Those which do not seem to be attacked, or, if so, but slightly, should be washed with soapy water, in which a liberal solution of flowers of sulphur has been dissolved. The sulphur will settle at the bottom of the vessel, and must be frequently stirred up when the water is being used. Sulphur is very effective in destroying almost any fungus. When in time, and may this one in its very earliest stages, but it will not do so when it is once established.

Begonias dropping their flowers (S. H. A.).—The dropping of flowers in Begonias is due to the hot weather that we have experienced this season. The first half of July seems to have tried the Tuberosa Begonia very much, for we hear many complaints of their flowers falling this season. That infectious disease known as Begonia rust is very troublesome this season; but, as we say nothing about the foliage being attacked, we presume it is only the drooping of the flowers that gives trouble. In that case it is clearly caused by a check of some kind, but what that is can only be a matter for conjecture. We can only suggest drought at the roots or the soil, while the manure used may have been in too high a state. The answer to "Paddy" on Begonias in issue 3, p. 290, may be of service to you.

Conservatory and plants (J. G. A.).—So far as we are able to gather from your letter, there is nothing really wrong with the structure itself to cause such an absence of bloom and so many general failings. We consider, therefore, there is a local cause or causes that are not clear to us. The glass predominating in the structure should, by reason of its position, favour the good growth of the plants. The fact that "Ferns do not thrive" would indicate a general absence of sunlight and sunheat, and the failure to flower at this season of the year of the very best seen Geraniums, so often brought into good bloom in cottage windows where little sun reaches the plants, would confirm this view. Then you say the Geraniums that are brought into bloom outside soon lose their flowers when taken into the conservatory, so it is obvious sufficient light and warmth do not reach the plants. In the circumstances, the only hope of turning the conservatory to account would be to make it a cool or shady tunnel, for, if Geraniums and such-like will not bloom therein, there is certainly no hope for Roses and other things that of necessity depend upon wood that is

well matured. Plants that could be recommended as companions to the Ferns are Candelabras, white and red Lapagerias, etc. If you still wish for flowering plants, greater light must reach the building, by removal of either shrubs or trees.

Tufted Pansies—when to propagate for autumn planting (E. G. H.).—There are several advantages in autumn planting; but to obtain the best results it is important that you commence operations without delay. Too often the insertion of cuttings is deferred till too late, and for this reason one hears of complaints of failure. If your requirements are not over-large, you should have little difficulty in obtaining cuttings from the plants now flowering in your beds and borders. It is only when a very large quantity of stock is needed that it is necessary to cut back the old plants. The object of this cutting back is to induce the plants to make fresh growth. If the soil round about the plants be forked over, and also mulched with some light and sandy compost, working the latter into the crown of the plants by the aid of one's fingers, a change in their appearance will be seen very soon. Copious waterings will give a much needed stimulus, and the resulting stock will be cuttings that will root very quickly. Referring again to the requirements of an ordinary individual, he can obtain just now beautiful stock pieces in the crown of his plants. These should vary in length from 2 1/2 inches to 3 1/2 inches in length, and, if rather more than ordinary care be observed, they may be detached with fresh young roots adhering. With material such as this the future is assured, and by the early days of October charming little tufts should be ready for planting out in their flowering quarters. You cannot at present do better than make up a slightly raised bed in a cool quarter of the garden for the cuttings. Let this be of a light and sandy character, and before the cuttings are inserted see that the surface is made even and level. Insert the cuttings some 2 inches apart, and allow rather more space between the rows.

Plants not growing (John Thomas).—We have always every hope of any soil that will grow a good crop of weeds; but, as you say yours will not even do this, we are rather non-plussed. Still, there must be a reason for such a failure as this, and we confess we do not know a similar instance. Are you sure you have really dug it? We ask this question pointedly, because we know instances where digging 3 inches deep has been regarded as sufficient, and, judging by the plants sent, the roots have certainly had no opportunity for descending. The few roots are in a tuft, as though the soil at 3 inches deep was quite hard and more or less opposed to roots getting through it. Provided there is a fair depth of soil, and that it has not been poisoned chemically or otherwise, we see no reason why it may not be brought into cultivation. We therefore suggest trenching, or, if the soil will not move, a double trenching, so that the whole area may be brought to a depth of 11 inches or 24 inches. This, with a further good manuring, should help matters considerably. By doing this in early autumn, and applying a further surface-dressing of old manure during frost in winter, to be pricked in with the fork in March, you may expect better results another year. We imagine a hard "pan" exists a few inches from the surface that fine roots will not or cannot penetrate, hence the plants are starved. In future abolish trenching when planting small things, as Stocks. Treading may be quite right for trees and plants of strong, vigorous growth. Smaller things, as Stocks, Asters, etc., if planted with hardfork, are best when gently firmed by the fingers of both hands pressing the soil about the stem and roots.

TREES AND SHRUBS.

The Yew-tree (Taxus baccata) (M. E.).—This is responsible for causing heavier losses to farmers than all the rest of our native poisonous plants put together. Cattle will eat green parts of the leaves and twigs of this tree, and seldom survive the indulgence. Cases in which they have not only survived, but were apparently nothing the worse for eating plentifully of Yew-leaves, have led some persons to deny the existence of any poisonous properties in the Yew. The truth of the matter, however, is that in the early part of the year the young spring growth shoots of the Yew, which are very plainly distinguishable from the older wood by the tender light green hue of the leaves, contain but little, if any, of the poisonous property, and, consequently, at that season, cattle may browse upon these young shoots to their heart's content without being anything the worse for doing so. Later on, however, when the foliage of these shoots of the Yew has become of a dark green colour, as the rest of the tree, it will also have become equally poisonous, and cattle will no longer be able to browse on it with impunity. As the poison of the Yew is rapid in its effects, it is hardly possible to save any animal that may, unfortunately, have partaken of it, and the only thing that remains in prevention by excluding the Yew from the list of trees on the farm, and by fencing carefully against it when it grows on land adjoining, if it is necessary to do so.

VEGETABLES.

Road sweepings as manure (H.).—Road sweepings are excellent for all kinds of vegetables. For Celery have the sweepings laid in a heap for a few weeks, and empty the house-slopes over it, turning it over once or twice. The best way to apply it is to dig it in; it also does well for mulching over the tops of all crops that require such assistance. It is not so rich as the manure from stall-fed cattle, as it is altogether minus the urine, which is the most valuable constituent. Use plenty of it, and the result will be satisfactory.

Woodlice in Cucumber-pits (J.).—In order to clear the pits from woodlice, remove the heating materials as soon as the crop is cleared out, then fill up all the crevices in the walls with mortar, and thoroughly drench with boiling water any portions of the pit where any of the woodlice may have found shelter. The best trap for woodlice are ordinary flower-pots, half filled with dry hay and baited with slices of Potatoes. They will congregate in these, and if emptied out every day into a pot of scalding water their numbers may soon be reduced to reasonable limits.

FRUIT.

Unfruitful wall-tree (W.).—We should expect in this case that the roots of the trees have penetrated too deeply into the earth, as we cannot believe that when the roots are near the surface healthy fruit-trees of good kinds

will, year after year, fail to produce blossoms. The remedy we should suggest would be to lift the roots, doing the work at the end of next October. Keep the trees clean and free from insects, and the shoots should be trained in thinly, and be well exposed to the sun.

Fig-tree not fruiting (B.).—Probably the Fig-tree requires more exposure to sun and air to mature its wood than can be had under the Peaches. The Brown Turkey Fig would be the most likely kind to bear well in such a position. Keep the young shoots very thin.

Watering a Vine border (A.).—The water given to an outside Vine-border, the Vines in which are just colouring their fruit, must entirely depend upon the weather. If it is hot and dry the soil should receive enough water at all times to keep it quite moist, but after the Grapes are coloured as they are wanted to hang for some time less water will be needed, but it would be unwise to let it become quite dry. As the Vines are heavily cropped they will take a good deal of moisture with advantage, and it would be a good plan, if the weather is dry and hot, to give a thorough soaking of water now, and this should carry them on for two or three weeks when more may be given. Air should certainly be left on the house at night as well as by day.

SHORT REPLIES.

Oakley.—If the autumn is favourable the Grass may require cutting, which should be done at first with the scythe, but if not it is better to leave it until the spring till you find it requires mowing. If the ground is well done, no artificial manure will be required. Roll after sowing, and beat it down to make a good bottom. Percy S. White.—Yes, the Logan Berry may be increased in the same way as the Blackberry—viz, by layering.—John Penhall, M.D.—I should say "Villa Gardening" from this office, privo 68, post free, should answer your purpose.—S. D. Broten.—Caused, no doubt, by the cold, unseasonable weather that you say you have had in your district. The same thing has happened in many Southern gardens.—Lawrence C. Higgins.—The only reason we can give is that in all probability the plants are too thick, and are thus starved.—Richard.—You had better get "Hobday's Villa Gardening" from this office, price 6s. 6d., post free.—Marion Fowler.—See reply to "W. T. G. H." in "Asters" talking, in our issue of Aug. 2, p. 328.—W. Harrison.—The only thing we can suggest is an oil-lamp for such a small house.—P. M. G.—It not too large, the best thing you can do is to lift it and replant, adding some good loamy soil about the roots. The soil in which it is growing is evidently very poor and thin.—Muscat.—See article on "Air-roots on Vines," in our issue of July 5, this year, p. 244.—A Nuisance.—See reply to your own query under initials "A. N. T.," in our issue of August 9, p. 317, under the heading "Short Replies."—Gardener, N. B.—Many such have been raised from seed.—R. S.—See reply to "Kustic" in this week's issue, p. 329. Evidently your Pear-tree roots have gone down into a bad soil, and must be lifted and brought nearer the surface. Try this, adding some good loamy soil round the roots.—S. Ribbans.—See reply to "Fowler Ward," re "Flgs failing," in our issue of Aug. 9, p. 335. Other query next week.—Constant Reader. The number you inquire about can be had of the publisher, price 1/6d., post free.—R. W. Z.—We suppose you refer to Gunnera scabra, which was figured in our issue of Feb. 10, 1900, p. 651. This can be had of the publisher, post free, for 1/6d.—F. J. B.—It is quite impossible to assign any reason for the death of your plants. Are you quite sure that you followed the directions issued with the insecticide?—E. W. L.—No, grow on the Cucinerias freely without any special, taking care to grow them cool and keep clean. Yours must have been very fine plants.—2. You get no idea as to what size of pots your Vines are in.—Christus.—We do not know to what weed you refer. The best thing you can do is to employ someone to look after the churchyard, mowing the Grass when necessary and keeping the paths, etc., tidy.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcel, which should be addressed to the Editor of GARDENING ILLUSTRATED, 17, Furnival-street, Holborn, London, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—Matthias Craven.—We cannot name Horista flowers. Any hardy plant nurseryman should be able to supply Pink Napoleon III.—Aberny.—Botanogonon Butans.—J. C. Harrop.—The Japanese Bell (Humulus japonicus) is an annual.—V. D.—Periplora green.—Helen H. Menck.—Helesterium autumnale.—David Turner.—Hedychium Gardnerianum.—E. R. Hammerley.—We cannot undertake to name floriate flowers, such as Roses, Pelargoniums, Carnations, etc.—Torynay.—Sedum trifidum.—Miss Mainwaring.—1, Specimen insufficient, should like to see leaves as well; 2, Mueveralia rosea.—T. W. Quarmby.—Asparagus plumosus. Easily increased by division in the spring, or it can also be increased by seed.—Judy Audrey Ryder.—1 and 2, Not recognised; 3, Probably Sedum album, should like to see lower part of plant.—H. V. M.—Specimen insufficient.—Husko.—1, Lantana nuda var.; 2, Diplazium esplentenii; 3, Cape Adiantum (Flemingia papilion); 4, Begonia acaulis.—C. A. H.—Campanula pusilla alba.—Clare Grindley.—The Smoke-tree (Rhus Cotinus). Easily increased by root cuttings, layer, and seed.—David Jones.—1, tierculium arantianum; 2, Campanula Rapunculata; 4, Campanula persicifolia; 6, Alyssum sp.—Oakley, Preston.—Lavender Cotton (Santolina incana).—Mrs. Gee.—Should like to see complete flower and leaf sent in small box.—Alice M. Beseford.—Quite impossible to say from such a dried-up specimen and with no particulars.—Watson.—Achillea ptarmica The Pearl.

Catalogues received.—James Veitch and Sons, Chelsea, S. W.—Hardy Trees and Shrubs; Bulb Catalogue for 1902; New Fruits, Noctules, etc.—J. Van Reizen and Son, Voorhout (Holland).—Wholesale Price List of Dutch Fruits and Plants.

GARDEN & PLANT PHOTOGRAPHS, 1902.

THE EDITOR OF GARDENING ILLUSTRATED announces Photographic Competition for the season of 1902.

Class 1.—SMALL GARDENS.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS for the best ten photographs or sketches of picturesque small gardens, including town and villa gardens, rectory, farmhouse, or cottage gardens.

Class 2.—FLOWERS AND SHRUBS OF THE OPEN AIR.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS to the sender of the best series of not less than twelve photographs of the above. These may include wild plants or bushes, or any plant, flower, or shrub grown in the open air, including also half hardy plants put out for the summer, and either single specimens or groups, or the effects resulting therefrom, in beds or borders. Shoots also of rare or beautiful plants photographed in the house may be included in this class.

Class 3.—INDOOR FLOWERS AND PLANTS.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS for the best series of indoor plants—greenhouse, stove plants, Orchids, or any other plant not of the open air—either single shoots, plants, or specimens, or the effects resulting from good grouping or other arrangements of such plants separately or in association with others. Ferns or groups of Ferns in houses may be included in this class.

Class 4.—BEST GARDEN FRUITS AND VEGETABLES.—A prize of FIVE GUINEAS and a SECOND PRIZE OF TWO GUINEAS for not less than twelve photographs of the best kinds of garden fruits and vegetables, Grapes, Peaches, Apples, Pears, Plums, Cherries, or any other fruit grown in Britain, to be shown singly or on the branches. Overcrowding, as in dishes at shows, should be avoided. The aim should be to show well the form of each kind, and as far as may be life-size. The object of this is to get good representations of the best garden fruits and vegetables under the old names, though we do not want to exclude real novelties when they are such.

Class 5.—GENERAL SUBJECTS.—A prize of FIVE GUINEAS will be awarded for the best twelve photographs of any garden subject not included in the previous classes, such as water gardens, waterside effects, rock gardens, picturesque effects in gardens, vases, cut flowers, table decorations, and pretty garden structures.

All competitors not winning a prize will for each photograph chosen receive the sum of half a guinea. In order to give ample time to prepare good photographs the competition will be kept open until November 29th, 1902.

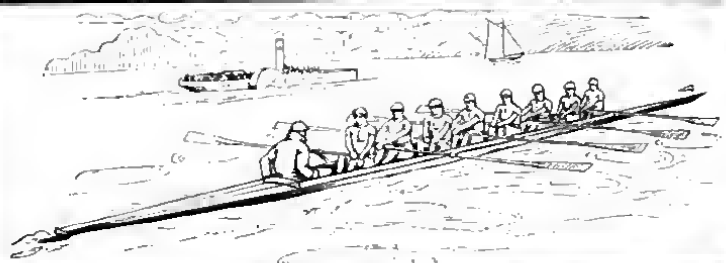

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with flowers. Figures of men or women, barrows, watering pots, rakes, hoes, rollers, and other implements, iron railings, wire, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. The subjects should not be overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none the copyright of which is open to question must be sent. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly. Platinotypes and bromides should not be sent, but those on albumenized and printing out papers are preferred for engraving. All photographs should be properly toned.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. Care should be taken to avoid the ink being seen on the face of the photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor, 17, Farnival-street, Holborn, London, E.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." Unsuccessful competitors who wish their photographs returned must enclose sufficient postage stamps for that purpose.

CAMBRIDGE

LEMONADE

"BEATS ALL"

"AS GOOD AS CHIVERS' JELLIES."

That is very high praise indeed for the Cambridge Lemonade, because the Jellies are recognised to be the best that can be produced. Same firm, same high standard of excellence. The Lemonade is made from Lemons and Sugar. No foreign acid added. 5d. per bottle. Goes farthest. Ask your Grocer, or send 6d. for sample to Chivers & Sons, Ltd., Histon, Cambridge, where Chivers' Jellies are made.

The Cambridge Lemonade is carefully prepared from selected Sicilian Lemons, and is guaranteed to contain the natural refreshing constituents of the fresh ripe fruit, free from any added acid or other injurious ingredient.

5½d. per bottle, sufficient to make 2 Gallons delicious Lemonade.

CHIVERS & SONS, LTD., HISTON, CAMBRIDGE.

Proprietors of the First English Fruit Growers' Jam Factory.

CLAY'S FERTILIZER

Produces Flowers, Fruits, and Vegetables for Exhibition, Pleasure, and Profit, in the HIGHEST DEGREE OF PERFECTION.

It is Safe, Lasting, Economical, & Unsurpassed for all Horticultural Purposes.

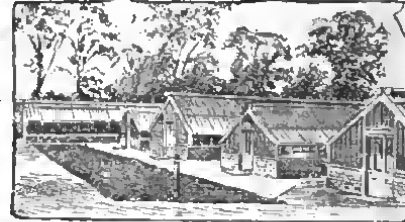

AMATEURS WIN PRIZES WHEN USING IT. HAVE YOU TRIED IT?

Sold everywhere in 6d. and 1/- Tins; and in SEALED BAGS—7 lbs., 2/6; 14 lbs., 4/8; 28 lbs., 7/6; 56 lbs., 12/6; 112 lbs., 20/-; or direct from the Works, Carriage Paid in the United Kingdom for Cash with Order, except 6d. Tins.

Full Price List of Manures, Chemicals, and Sundries upon application.

CLAY & SON, MANUFACTURERS, STRATFORD, LONDON, E.

WILLEDEN GREEN ROT-PROOF SCRIM SHADING

Shading Conservatories, Greenhouses, protection of Fruit Trees, and other Horticultural purposes.

In use at leading gardens and estates.

Supplied in any quantity, 36 in. or 60 in. wide.

Blinds of all kinds made to order.

Willowden Canvas, Tent, Ground Sheers, Etc., Awnings, Garden Aprons and all purpose uses a rot-proof and pliable material is required.

Willowden Roofing for Tool Houses, Sheds, Lomas, &c.

Samples free.

Telegraphic Address: IMPERMEABLE, LONDON.

WILLEDEN PAPER & CANVAS WORKS, LTD., LONDON, N.W.

POCKET KNIVES FROM MAKER.

Stag Handle Pruning Knives, a real good article, 1s. 1d. each; Ivory Handle Bulldog Knives, an better made, 1s. 2d. each; Ivory Handle 2-blade Waistcoat Pocket Knife, 1s. 1d. each; Corn Knives, 1s.; Workmen's Stag Handle Sheepsfoot and Pen Blade, 1s. 1d. The blades of all the above are made from the very best English crucible cast steel. Post free.

PRICE LIST FREE.

J. and H. R. HOUNAM,

Sheaf Island Works, SHEFFIELD.

15/-

FOR ROOKS, PIGEONS, RABBITS.

Single barrel, hammerless, breech-loading Shot Gun, converted from Government Rifle, and fitted to take 12-gauge CF shot cartridges; specially bored by an improved process for long range and great penetration. Unsurpassed for long distance shooting, 15s. each. Double-barrelled breech loaders from 3s. Air Guns, 12s. 6d. Walking-stick Gun, 22s. 6d. Alarm Guns, 1s. 6d. Send 3 stamps for Price List.

MIDLAND GUN CO., Bath-street, Birmingham.

PLANTS AND FLOWERS.

INDOOR PLANTS.

GROWING FIBROUS-ROOTED BEGONIAS.

It will be much obliged if you will give me some hints as to the culture of the very useful perpetual-flowering Begonia? I have Haageana, President Carnot, Gloire de Beauv, Gloire de Lorraine, A. Malet, metallic, corallina, and others. The principal points on which I ask for information are: 1. Should they be cut back, and if so, when? 2. What amount of heat do they require? 3. Do moderate stove-houses, an intermediate-house, and a cold-house. 4. Do they require nutriment, and if so, of what nature? They are not much grown hereabouts, and gardeners are ignorant as to them.—R. N.

The different Begonias included in this section have within the last few years made a considerable advance in popular favour. Generally speaking they are of easy culture, and cuttings are not at all difficult to strike, and a soil consisting of two parts loam to one part each of leaf-mould, and well decayed manure, with a little sand, will suit them well. Most of them are valued more for the sake of their flowers in the winter than at any other season, hence the cuttings are usually struck in an early spring and the plants grown on throughout the season, so that by the winter they will be well furnished specimens ready to commence flowering.

Cutting back will depend upon various circumstances, as many of them may be grown in large and handsome specimens—that is, if you have room for their full development. To carry this out they will need to be shifted annually into larger pots. If, however, you prefer smaller plants, the most satisfactory way is to allow them to bloom as long as they are effective, and when this stage is over to fill their place with young ones grown from cuttings for the purpose. Where there are no young plants in reserve this cannot, of course, be done, in which case the old plants should be cut down about April, and as soon as they start into growth be again repotted. For this potting a considerable portion of the old soil may be removed, but, of course, not sufficient to distress the plants. When the old plants are cut down they must be kept somewhat drier at the roots till the young shoots make their appearance. Most of these Begonias are what may be regarded as intermediate house plants—that is to say, they will do with a greenhouse temperature in the summer, and to flower in the winter they want more heat—indeed, if flowers are required at any particular time they may, if necessary, be taken into the stove to their advantage. Generally speaking, however, an intermediate house temperature is the most suitable for them. As the pots get full of roots and the flowers develop, a stimulant in the shape of liquid-manure is very necessary. The best manure is made from sheep or cow-dung with a bag of soot dissolved in it. Failing this, any of the concentrated manures, of which numbers are now sold by horticultural sundriesmen, may be used, but though very swift and certain in their action, and cleanly to use, they have not the lasting properties of natural manure.

CULTURE.—A few words as to the culture of these Begonias, apart from the items above enumerated, may be of service. In taking the cuttings in the spring the clean-growing shoots should be chosen, not those that have flowered until they are almost, if not completely, exhausted. A length of 3 inches to 4 inches is a very suitable size for the cuttings, which should be taken off at a joint, the bottom leaf or leaves removed, and dibbled into well-drained pots of sandy soil, such as equal parts of loam, leaf-mould, or peat, and sand, the whole passed through a sieve with half-an-inch mesh. Then, if placed in a close propagating case in an intermediate or stove temperature they will soon root. Directly this takes place more air must be given, and as soon as possible pot the cuttings into 3-inch pots. When the roots take hold of the new soil pinch out the tops of the young plants in order to induce a bushy habit of growth, and as soon as they are sufficiently advanced they may be potted into 5-inch or 6-inch pots, according to their vigour. During the summer, when growing, a cold-frame is a very suitable place for them. These remarks, however, must be taken as general, for with the varied selection now obtainable no hard-and-fast line can be laid down—for instance, Gloire de Lorraine and its variety Turnford Hall (the best of the light-coloured forms), need different treatment. They usually decline in blooming by February, when the plants may be partially cut back and kept somewhat drier for a month or so. After this, if taken into a little more heat, they will push up shoots from the base, and when these are from 1½ inches to 2 inches long they form the best of cuttings, if taken off with the thickened base from whence they spring from the old plant. Beside the varieties enumerated in your letter, which are, however, among the very best, there are numerous others, all of which are well worth cultivation—viz., Carrière, a free-flowering white kind particularly valuable for winter; Dregei, white, very free, and of interest as being one of the parents of Gloire de Lorraine; fuchsioides, bright red; hybrida floribunda, coral-red; insignis, pink; Knowlesiana, bluish; maui-cate, flowers small but borne in large branching spikes about February, when it is very attractive; Paul Braunt, pink; semperflorens gigantea rosea, one of the most useful and most robust in constitution of all. Of semperflorens, too, there are several double-flowered varieties of comparatively recent introduction which are very pretty, and attract by reason of their distinct appearance. Of those that have come under my notice the best are: Bijou des Jardins, carmine; Boule de Neige, white; and Stuttgartia, pink. A delightful species of Begonia for a hanging-basket is B. undulata, known also as B. glaucophylla and B. Comte de Limminge, which was recently figured in GARDENING ILLUSTRATED.—T.]

Gloxinias.—The needs of Gloxinias just now are shade from hot sun in the day, and, if the weather proves cold, a fire in the stove at night and the cold water. Dryness at the roots must also be guarded against, and in

staging in the house on which fine ashes are spread and can easily be kept damp suits them. Under no conditions are they better grown than when in the warm, humid atmosphere, such as that of a Cucumber-house, and the partial shade under the Vines is calculated to bring out their lovely colours and retain them for the longest possible time.—LEAHURST.

FLOWERS AND VEGETABLES FOR MARKET SALE.

(REPLY TO "BROWN EYES.")

It is well at the outset to say that oven with two greenhouses heated you must not expect to obtain from them any great deal of stuff to sell during the winter. You would probably find the cost of heating the houses, and growth would be slow unless well heated, would equal if not exceed the profit derived from the produce. Market work seldom pays, except when it is conducted on a fairly large scale and by experienced growers. Of vegetables with a heat ranging from 65 degs. to 75 degs. you may grow Cucumbers, and with a warmth 10 degs. less you may grow Dwarf French Beans, such as Ne Plus Ultra, in pots, keeping up successional sowings all the winter at least once a fortnight. So much would then depend on the sort of market you found. Winter Tomatoes will not pay. If you had raised every year from root cuttings several hundreds of strong roots and crowns of Seakale to force in a dark place, that might prove the most profitable. Asparagus and Rhubarb would need so much room and long culture to make forcing roots. Of fruit, if you had put out each year early strong runners of Royal Sovereign Strawberry, from which to obtain strong early runners to lay into pots in the summer, not allowing the plants to carry flowers, and later got these rooted runners shifted into 6-inch pots, and put them in warmth on shelves near the glass in betches from January onwards, you might get from them good fruit to sell. As to flowers, your best would be Roman Hyacinths, clumps of Lilies of the Valley, various Daffodils, all grown in pots, white Azaleas, some late white and yellow Chrysanthemums, scarlet Van Thol Tulips, white-flowered Cyclamen, The Bride, Niphetos, and Catherine Mermet Roses in large pots, scarlet Salvias and some strong white and yellow Paris Daisies. But, of course, of these things you need a constant succession to keep up a supply of flowers for several months.

NOTES AND REPLIES.

Dielytra spectabilis in pots.—For blooming early in the year in the greenhouse this Dielytra is charming, its rosy-pink blossoms bearing a marked contrast to others then in season. It is one of our hardiest herbaceous perennials and forces easily, so that those who desire variety amongst their bulbs, etc., cannot do better than pot up a few clumps this autumn, placing them in a cold frame or shed until they have become established. Dielytras really need little heat to bring them into bloom, but like Spiraea and Clematis they are very thirsty.

subjects; on this account some take the precaution to place the pots in saucers to avoid their becoming dried up.—LEAHDURST.

Greenhouse sundries.—During the summer months it is a good plan to overhaul one's stock of flower-pots, washing them, if at all dirty, so that they may be at hand clean and ready for use in the autumn. Seed-boxes, also, often need a little attention before they can be brought into use, either for growing cuttings or seed sowing later, and if seen to in time such boxes often last for years. Opportunity should also be taken to get together a supply of potting material, turf stacked together, a heap of rotted stable-manure, leaf-soil, sand. There is no time like the present to procure these, so that the work of potting plants and cuttings may proceed without interruption when the time arrives.—W. F. D.

Striking Coleuses.—If it is desired to increase the stock of Coleuses at this time of the year, then no opportunity must be lost to get in the cuttings at once, as they will strike freely. How few there are after all who grow more than a few in their houses, and, really, the trouble of keeping them in the warmest part of the house the winter through does not always guarantee their surviving, for in March they sometimes damp off. Far better, I think, raise plants from seed, or purchase the few wanted in spring.—WOODCASTWICK.

The Maiden's Wreath (*Francoa ramosa*).—A couple of plants of the Maiden's Wreath that are kept in the window of a house I pass daily have been in bloom for many weeks in succession. One of the reasons why these particular plants have done so well, and they are always in the window the year round, is because the inmates believe in fresh air, and above anything else Francoas need it. Although they last for years in the same pot, young plants bloom more freely, and bearing this in mind, one should be prepared with seedlings, and to this end seed should be sown in March or April. Good loam, with manure added, is what they do best in. The blooms of Francoas can not retain their freshness some time.—WOODCASTWICK.

Lilies in pots after flowering.—Can you give me the proper treatment of pot Lilies, such as auratum and longiflorum, after they have done blooming?—E. A. R. W.

[Your Lilies may be placed out-of-doors and watered as before till the leaves turn yellow, when the supply must be diminished, but at no time must they be parched up. Then when the flower-stems are quite dead re-pot them. If the roots are in good condition pots 1 inch or even 2 inches wider may be used. They should be stood out-of-doors for a time in a sheltered spot, under which treatment the roots will soon take possession of the new soil. Then when frost sets in remove them to an ordinary garden frame or to the greenhouse. As soon as they commence to grow see that they have as much light and air as possible. You will find that as a rule those kept over from the preceding year flower somewhat earlier than freshly imported bulbs.]

Making up Violet-beds (*N. W. L.*).—When and how to prepare beds for Violets, for blooming during the winter, will soon be engaging attention. The middle of September will be found early enough to remove them from the beds where, as runners, they were planted early in the season, and in digging them up care must be exercised, in order that the roots may not be disturbed any more than is absolutely necessary. Very often promising crowns have been ruined, so far as winter flowering is concerned, by a rough and ready method employed in shifting them to a frame. The best of all composts is good fibrous loam, leaf-mould, and sand, with a fair proportion of rotted stable manure, but there, again, one must be satisfied that the manure has stood and become "mellow," as new manure, still fermenting, is another cause of failure on the part of the new grower. I once saw a frame full of promising plants sicken and go yellow in a few days, simply the result of over-kindness by making up the bed with new stable manure. Manure that has stood in the open six or nine months is what is required, and if it can be got composed partly of cow-dung so much the better, but rather than run the risk of new I would stick to turf-pit and leaf-mould.—TOWNEMAN.

ROSES.

QUICK-GROWING ROSES FOR WALLS, ETC.

I HAVE just taken a house with an old garden of great possibilities. I wish to go in specially for quick-climbing roses, as the house and garden lend themselves, I think, to the same. You are so kind in giving full particulars to your readers, that perhaps you will not mind affording me the benefit of your advice. At present the garden, which faces S.S.W. and S.E. respectively, contains a good many Rose-trees in the beds, and, as climbers, a couple of fine *Gloire de Dijon*, and an old-fashioned white cluster Rose. The ground is high (40 feet above sea level), soil rich and loamy, plenty of air and space. Would you mind giving colour as well as names?—E. D. ROSEK.

[Although you say your soil is rich and loamy, we would advise you to have the borders well prepared, especially as regards drainage. As you desire the walls covered quickly, it is not merely essential to select fast growing kinds, but they must be encouraged to grow quickly by affording them a good root-run. We should advise you to prepare the borders quite 3 feet deep, adding some good lasting fertiliser in the form of $\frac{1}{2}$ -inch bones. Such a manure as this is safe and most supporting. Moreover, it can be supplemented by annual surface dressings of farmyard manure. We append a list, with colours, as requested, placing the varieties in order of merit.

FOR WALLS.—Reve d'Or, apricot and daisy yellow; Climbing Niphetos, pure white; Climbing Kaiserin Auguste Victoria, creamy-white, a splendid Rose; Reine Marie Henriette, light crimson, a well known Rose, sometimes badly attacked with mildew; and Climbing Perle des Jardins, golden-yellow, the next best to Maréchal Niel, which should succeed well if given a sheltered corner and not overcropped. If you would prefer Maréchal Niel, plant a half-standard of it against the wall, and prune back hard the first spring. Climbing Devonensis, a grand old kind with flesh-white, fragrant blossoms of great size, should be allowed to ramble at will for a year or two, and then all the hard wood carefully laid in, pruning back the laterals only, save cutting out any worn-out wood. Waltham Climber No. 1, bright red, lovely in bud, is as regular in petal as a Camellia. Souvenir de Mme. Joseph Meitral is a splendid flower of exhibition size and of a cerise colour. Lamarque, one of the favourites of hygone years, is even to-day unsurpassed, although very tender; the sulphur-white buds and blossoms are very beautiful. Jaune Desprez is a free-growing and hardy kind, of mixed colours—red, buff, and sulphur. Fanny Stolwerck has coppery-carmine buds, open flowers yellow and rose. Noella Nabonnand bears huge semi-double flowers of velvety crimson colour and exquisite buds.

FOR ARCHES.—As you ask for Roses of better quality than the Crimson Rambler, we name the following, the first seven being large-flowered kinds: Mme. Berard, apricot and salmon; Mme. Alfred Carriere, blush-white, distinct and beautiful; Celine Forestier, pale yellow flowers, flat, a well-proved variety of sterling worth; William Allen Richardson, unique in colour, which is orange-yellow; Reine Olga de Wurtemberg, a semi-double crimson, almost evergreen Rose of wonderful vigour; Marie Lavallee, a lovely semi-double flower of delicate beauty, rose and white in colour; and Chasunt Hybrid, which is not admired exactly when fully out, but the buds are pretty, colour magenta. Any of the above would also be good on the walls. The following are grand Roses for arches, and although small in blossom, they make amends for this by their profusion: Electra, yellowish-white; Claire Jacquier, nankan-yellow; Flora, pink and white; Euphrosyne, pink; Thalia, white. We have not named Felicite-Perpetue, as from your letter we believe you already possess the variety. There is one Rose, not so very fast in growth, but indispensable on wall or arch, and that is Deschamps or Longworth Rambler; colour bright carmine, splendid in autumn.

Whilst the climbers are making their growth you could very well plant between each pair some of the less vigorous Teas, such as Marie Van Houtte, Catherine Mermet, Souvenir d'un Ami, etc. They would afford you a quantity of blossom. Such varieties will frequently attain a height of 8 feet to 10 feet on a wall.]

PRUNING VARIOUS CLASSES OF ROSES.

IN an early issue would you kindly tell me how and when to prune the following or other classes of Roses—viz., Hybrid Perpetuals, Teas, Noisettes, Scotch, and other climbers, and the reasons for same?—G. B. BASKETT.

[The Hybrid Perpetuals, Hybrid Teas, Teas, and, in fact, all Roses not climbing, are pruned in spring, generally early in March, and we would refer you to our back numbers for full information on this important subject. But there is such a thing as summer pruning of Roses. With the Teas, Hybrid Teas, Hybrid Perpetuals, and all classes that flower again in autumn, it is a good plan to go over the plants and slightly prune the growths that have flowered. This consists in removing an inch or two from the shoot, cutting them down to the first plump bud. The work needs to be done very carefully, for we must not remove more foliage than is necessary, neither is it advisable to prune too low, as by so doing the bottom eyes are induced to start, and this would be a misfortune, as they will be required for next season. Scotch Roses, Rugosa, Austrian Briers, etc., are best left alone beyond thinning out the growths when they become too dense. Climbing Roses that flower again in autumn, such as the Teas and Noisettes, benefit considerably by a good thinning out of the weakly and old wood as soon as the first flowering is over, carefully preserving all sound, well-ripened growths, and spreading them out to admit light and air. Do not on any account shorten the long growths formed this season—at least, not at present. Next month they might have their points pinched out, which would tend to ripen the growth better. Rambler and other rampant growers of summer blooming habit are best thinned in September, and very little, if any, pruning is required in spring. Where such Roses have grown luxuriantly they should be carefully taken down from their supports and overhauled, cutting out the old and dead wood and any that looks debilitated, afterwards carefully tying out the best young wood. It is quite true that one meets with old specimens that have, perhaps, received no pruning whatever, and they are a sheet of bloom. This is quite true, but if the plants had been well thinned from the commencement, the trusses of bloom would have been finer, and the flowers of a better colour.]

TWO CHARMING POLYANTHA ROSES

THE very interesting group of dwarf Polyantha Roses is of comparatively modern introduction, one of the first varieties, Paquette, having been introduced by Guillot some twenty-seven years ago. Their origin is supposed to be the result of crossing *Rosa multiflora simplex* with a Tea Rose. Now we have quite a charming group, two of the best recent novelties being Eugenie Lamesch and Leonie Lamesch. The former has tiny Ranunculus-shaped blossoms, orange-yellow in bud, prettily tipped with crimson, changing to pale yellow as they expand. It rarely exceeds 18 inches in height, and is therefore useful as an edging or for small pots. It was raised by crossing Aglaia with William Allen Richardson, and is a very remarkable hybrid, seeing that the two parents are very vigorous-growing kinds. The great merit of this Rose is its diminutive blossoms. One does not care to see the group developed into a large-flowering one after the style of the Tea Rose. Already we have some varieties that nearly approach the Tea, for instance, Mosella, which has flowers almost as large as Hon. Edith Gifford. This is a departure in the wrong direction. What is wanted is very tiny flowers in huge clusters of all the lovely colours seen in the Teas. Leonie Lamesch is vivid coppery-red, if the word coppery conveys any meaning. It is really an intense orange shading, which merges into a red, with terracotta edges to petals. There is no more remarkable Rose in colour than this one. The one fault of the variety appears to be its inability to expand well, the petals seeming to be marred at the edges. Leonie Lamesch resulted from a cross between two seedlings. Both kinds named above were raised by Herr Lambert of Trier, Germany. Especially lovely are the snowy-white Anne Marie de

Montravel and Schneewitohen, recently noticed in these pages, also another charming white, Kathenna Zeimet. ROSA.

ROSE WHITE MAMAN COCHET.

The popularity of this splendid Rose increases every year. This season I think it has been the loveliest variety in our large collection. In White Maman Cochet we have a variety of vigorous growth and an abundant blossoming habit—good points in a garden Rose. As a white Rose the variety under notice is superior for outdoor culture to The Bride, although that lovely variety is good in a sheltered garden. To obtain the greatest perfection of blossom in White Maman Cochet and, indeed, all large Tea Roses, they should be upon half-standard Briers. There is something about the hedge Brier that gives character to these lovely Teas. The only disadvantage of having many of them is that they are not readily protected against severe frosts. I am much in favour of lifting the trees in November and heeling them in under a north wall or fence. Should the winter be severe it is an easy matter to cover with thatched hurdles or lean boards against the wall, previously covering the branches with dry Fern or straw. I would advise all who can

to be seen. A better way of showing how little we get out of the Rose as a standard could hardly have been devised. Here and there, it is true, a variety is so like the stock in character that it succeeds in making a handsome old bush, particularly the red Roses, but generally the standard Rose-tree is a delusion.

Rose Rainbow (H.T.).—This pretty striped sport from Papa Gontler is very interesting. Generally speaking, striped Roses are not much admired, but in this case the pretty markings of bright carmine upon a fresh pink ground seem to harmonise so well that all objection is dispelled at once. It is a useful long-budded variety, flowering freely.—Rosa.

Rose Ormeon Rambler.—According to my experience, no real success can be had in the culture of this Rose without high feeding. It is of a very vigorous habit, making when established, growths some 20 feet long, but it will not bloom freely unless the roots get abundance of food from the time the plants start into growth. In planting the soil should be well stirred to a depth of 3 feet, adding a good dressing of rotten manure, which will carry the young plants along very well for the first year without further aid. In following years a top-dressing of manure should be applied in the beginning of the winter, so that the plants get the benefit of it by the time they start

parations next month. It is better to devote a bed or border to the plants rather than dot them about here and there. Do not have the beds too large. Five feet across is ample. Trench the soil two spits deep, working in a liberal amount of well-rotted manure. Allow the soil to lie as roughly as possible until November, which is the best month to plant Roses. Be careful how you plant, for upon the work being well or badly done success or failure will depend. After unpacking the Roses great care is necessary, so that the roots are not unduly exposed to sun or wind. It is best to moisten them and roll them in a mat, taking out one at a time to plant. Mark out positions of plants in bed, then dig a hole about 1 foot square. An assistant should hold the plant in the hole, having previously trimmed off any jagged ends of roots, and then carefully spread out the latter; the planter then shovels in the soil, keeping the junction where the plant is huddled just beneath the soil, and treading the latter firmly round about the roots. If the variety is a tall grower, either shorten the shoots to 2 feet or so or give them a Bamboo-cane. After planting, lightly fork over the soil. To make them all safe, moulh up the base of each plant to a depth of 3 inches or 6 inches with soil, and you may rest assured that very little harm will befall them.]

Red Roses for a trellis.—I have a trellis 9 feet high running on the south side of a croquet lawn on the side of a chalk hill. I am taking the soil out to a width of about 3 feet, and filling it up with clay (ought this to be burnt first), road-scrapings, and short London manure. Will you kindly give me the names of some continuous blooming Roses, or Roses that have a double season of flowering? I want them bright red. I thought of Bardou Job, Gruss an Teplitz among them, or do you advise that new Rose, Noella Nabonnaod, or the whole length planted with a deep red China Rose, or would the whole trellis planted with Mme. E. Resal be best? Does this Rose flower twice in the year? I want a broad effect, and to last for some time. In front I thought of planting a thick row of Lilium candidum and lancifolium—they both do well with me. The length of my trellis is about 30 yards. How many Roses should I need to cover the trellis quickly—what distance apart?—T. C. SKERRATT.

[If you are able to procure locally some top-spirit of meadow loam we should advise you to mix this with the clay, road-scrapings, and short manure. Quite one half of the compost should be loam, if procurable, otherwise, if you are compelled to use mainly the clay, then it must be disintegrated in some way, either by the action of wind and frost or by burning. The varieties you name—Bardou Job and Gruss an Teplitz—are both excellent, especially the latter. It blossoms almost continually, is really a very good flower of pretty form, brilliant colour, and delicious fragrance. This Rose would not cover the 9-feet of space very rapidly, but you could plant some standards of Gruss an Teplitz in order to have blossom on the top of trellis fairly quick. An alternative plan would be to plant Noella Nabonnaod and Climbing Cremoise - Superieure alternately with Gruss an Teplitz and Bardou Job, the two former growing, as they do, more vigorously could have their growths trained horizontally when top of trellis is reached. Two other charming kinds to mingle with the four already named are Longworth Rambler and Gloire des Rosomanes. As you desire a quick effect plant 2 feet 6 inches apart. Whilst the stronger growers are filling out the space allotted to them a few plants of the brilliant Chim Fabvier could be planted in any vacant space on the trellis, to be afterwards removed if required. Mme. Eugene Resal is not strong enough in growth to cover a fence of this description even if it were red. It is a splendid continuous blooming Rose, the colour being rich rosy-pink. We think until the trellis is covered the Lilies should not be planted, as they would hinder the Roses from making growth as is desirable.]

Rose White Maman Cochet.

spare the time and have the means of access to country meadows to obtain some of the hedge Briers for themselves this coming October. They would find the work interesting, and one is sure of the Briers taking well if they are carefully planted the same day. A friend of mine obtained as many as seventy of these half-standard Briers in one day last autumn, and when I saw them recently they had made splendid growths, upon which he had budded the above Rose and many others. The only fault in White Maman Cochet is a tendency to become divided in the centre, but this is not nearly so frequent in the white as in the pink form. I believe that both Roses should be grown in rather a light soil. They seem to grow too rank in that of a clayey nature. It has been suggested that the Rose does not require manure, but I differ. I am of opinion that some phosphatic manure is of much assistance to the large blossoms, although this should not be overdone. ROSA.

NOTES AND REPLIES.

Standard Roses in Battersea Park.

Anybody who wishes to enjoy the beauties of standard Rose culture will see a farcical exhibition of them by one of the gates at Battersea Park, near the station. There are many trees with a few leaves and little branches on top, some of them dead, but not a flower anywhere

into growth. In the case of good-sized specimens a heavy coat of manure will be necessary or any good concentrated stimulant will serve the purpose, not waiting, however, until spring, but applying it in winter, so that it may be dissolved and carried down a couple of feet into the soil. As regards pruning, very little will be needed for the first two or three years; in fact, it is better to let the growths remain intact for a couple of seasons. When they become very crowded, some of the oldest growths should be cut out, which will promote the formation of strong shoots from the base.—C., Ryfield.

Roses for planting.—Can you give me a list of fifty Rose-trees suitable for a medium soil? I am not in want of fifty different kinds. I should not object to two or three of some varieties. I want them to be either H.P. or H.T. What preparation should I make for planting? I want some good Roses, but not for the show-board. Any information respecting varieties and planting will be thankfully received.—NOVICE IN ROSES.

[You will do well to put yourself in the hands of a good reliable Rose grower, and tell him what you prefer, and also describe the soil. It is far better to have a dozen good kinds—four or five plants of a kind—rather than a big collection. Roses of the type of Caroline Testout, Mrs. W. J. Grant, Gloire Lyonnaise, Fisher Holmes, Clio, etc., are what you require, and, when ordering, it would be best to mention these Roses as being the style you prefer. You should commence your pre-

Photographs of Gardens, Plants, of Tree.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Miss Wakefield, Nutwood, Grange-over-Sands, for Iris under Laurels; 2, Mr. Geo. E. Low, for Platycodon Stommaria.

CHRYSANTHEMUMS.

CHRYSANTHEMUMS FOR DECORATION AND CUTTING.

THE craze for large blooms is responsible for the decline of those sorts which produce their blossoms in abundance, the feeling uppermost in the mind of most Chrysanthemum enthusiasts being to produce blooms as large as possible. The small to medium-sized blooms have little to interest the ordinary Chrysanthemum exhibitor, as very rarely indeed are these useful blossoms seen, excepting perhaps in the exhibit of a decorative character, and then only to a very limited extent. One of the greatest mistakes a grower can make is to confine himself to what are usually termed exhibition varieties. After all, the period covered by the November exhibitions is very restricted, and during this time most of the best blooms have been cut, and often but little in the way of flowers remains to keep the greenhouse or conservatory bright in the dull season. It is the comprehensive character of the free-flowering kinds which enhances their value; they begin to blossom as early sorts in September or earlier, and continue through succeeding months until late December or early January, and by a special system of culture they will continue their display well into March. In the case of the large exhibition varieties, when their two or three blooms have been gathered, the plants are useless, except for stock, and then for months the old stools are not particularly interesting. The decorative Chrysanthemums, as a rule, produce such a wealth of blossoms that the grower may cut and come again.

To be successful with the decorative kinds, a great deal depends upon the selection of varieties. Plants for decoration, either as cut-blooms or for the embellishment of the greenhouse, should be free-flowering, and should also possess a good habit of growth. They should be branching and sturdy, and not over tall, and each bloom should be developed on a good length of footstalk, which should be sufficiently strong to keep the bloom erect. Pleasing form, and this also varied, has much to do with the popularity of each variety. Colour, too, is important. Good and distinct colours are always in demand. This does not mean that only one shade of each colour is necessary; as a matter of fact, there is room for many improvements on existing varieties, as, for example, in the case of flowers of a yellow colour, just imagine what effects could be produced were blossoms of the following shades of yellow available: Buttercup-yellow, rich yellow, bright yellow, rich primrose, soft or pale primrose, etc. Flowers of these distinct tones of colour would always be welcomed, and if each succeeding season gave us something new and dainty in form, we should then be making the progress that all true florists desire. I well remember a magnificent display of freely-grown Chrysanthemums arranged in the large conservatory at Glasnevin Botanic Gardens, Dublin, a few years ago. All types of the flower were represented: Japanese, incurved, large Anemones, Japanese Anemones, reflexed, Pompons, and Anemone-Pompons; all charmingly grouped together, and the plants were blossoming freely. In visiting the shows in different parts of the country, too, one occasionally meets with an exhibit of these plants. It is difficult to come to a satisfactory judgment when a group of decorative plants is put into competition with other groups of Chrysanthemums grown in the orthodox exhibition system of culture. The storotyped and formal system of grouping these plants which generally obtains will not compare for decorative effect with a group of freely-flowered plants; but the verdict has often to be given in favour of the formal group of large blooms, because the schedule says "quality" has to be one of the leading features. Quality is, unfortunately, usually regarded from the point of view of size only.

If the Chrysanthemum is to retain its popularity a greater share of attention will have to be given to the free-flowering sorts. Growers are more than ever coming to regard the flowers from a practical point of view—their use.

fulness for home displays both as plants and as cut-flowers. At the present time most of the interest centres around the large Japanese blooms to the exclusion of several other more pleasing and interesting types of the flower.

E. G.

CHRYSANTHEMUMS—BUD RETAINING.

THE present should be a busy period with all growers of large exhibition blooms. There is a time in the month of August when the buds of the different sorts should be retained, if each variety is to be represented at its best. Generally speaking, the third week of August is regarded as an ideal period for the buds of the bulk of the best Japanese sorts to be retained. A limited number of Japanese varieties succeeds better if the buds are retained during the earlier half of the month, and there are others which give far better blooms if the buds are retained during the last few days of this month. The method of cultivating the Chrysanthemum—at least, in so far as the development of large blooms is concerned—is to so manipulate the growth of the plants that they may produce their buds at a period best suited to their peculiarities. As a rule, when a bud is retained at too early a date the resulting bloom will be large and devoid of good form, and its colour will leave much to be desired. On the other hand, a bud retained at a later date than is desirable will develop a bloom of good form and bright and lasting colour, but in so far as substance and size are concerned it will be found wanting. The essential qualities of a good exhibition bloom comprise size, breadth, depth, form, colour, and substance. Many growers, when the time has arrived for a bud to be retained, rub out the whole of the side shoots at once. Such treatment is wrong. The small shoots which surround the bud at the apex of the growth are usually very brittle and full of sap. To detach the whole of these shoots at one time must of necessity check the plant—for a time, at least. The better method of retaining a bud is to rub out the side shoots one at a time, allowing an interval of one day at least between each succeeding removal of a shoot. In this way the plant suffers but little inconvenience, and within a week or so the bud is left at the apex of the shoot. The shoots on the lower portion of the stem will in some cases be somewhat tough, and to break these out from the axils of the leaves would be very injurious. In such cases they should be cut out, or rather cut back, close to their base.

In some cases plants of certain varieties may be developing their buds earlier than the grower thinks is best suited to their needs. The development of such buds may be retarded to some extent by permitting some of the stronger growing side shoots to remain on the plants. All that the grower need concern himself about is to see the buds are just moving, no matter how slowly. When this cannot be seen, one of the stronger-growing shoots should be detached. This relief will cause the plant and bud to again move forward, and the operation may be repeated from time to time with other shoots, until the proper period for retaining the bud has arrived. Should the weather be very warm and dry, it would be better to syringe the plants and buds lightly with clear water. It is important, too, to keep the shoots and buds in an upright position. Until the buds are nicely set it would be better not to feed. A few days will suffice for this, after which begin with weak doses and gradually increase the strength of the manure-water. Leave the incurved sorts till early September.

E. G.

EARLY-FLOWERING CHRYSANTHEMUMS AND WHY I GROW THEM.

MY earliest recollections of Chrysanthemums grown out-of-doors are of a few plants that I saw in a garden within a stone's throw of a road in a busy town. As far as my memory serves me now—it is thirty years since—there were only three varieties—a yellow, dark red, and purple, all being Pompons, and blooming about October. How we have progressed in the matter of open-air varieties, one has but to take stock of some of the present sorts. It was not until the advent of

Mme. Dea-grange, however, that very much attention was paid to the Chrysanthemum as a plant for blooming outside, but anyone who has watched the development of the early-flowering varieties must remember how the sort in question quickly became popular. It is not to be wondered at, for there are no plants in my estimation in early autumn that have such freedom of blooming, last so long when cut, and are so suited to town gardens as these. Who, at one time, would have anticipated being able to use Chrysanthemums for the flower garden? But now there are few gardens of any size that do not make provision for a bed of them for autumn blooming. To-day I have been stoking a number of plants that were put out in May; some of the earliest sorts are full of buds, and presently I shall commence to cut bloom, and will be able to do so until late in October, for they are planted under a wall, where they get some slight protection. Then one has also to bear in mind that early-flowering Chrysanthemums, when grown in the open-air, give very little trouble; in fact, beyond watering them once or twice during the very hot weather and stoking them, they have, I might say, given no trouble at all. I took the precaution a few weeks ago to mulch the surface of the bed with old manure, and the result has more than justified my doing so, for a more promising lot of plants I could not wish to have. This is why I grow early-flowering Chrysanthemums outdoors, and why in every garden they are worthy of culture. Mine are left out all winter, and all the protection they get is a little stable-manure drawn over the rows, and in spring a division is made of those that have become too large; in other respects they receive the same treatment as my herbaceous plants. Then, too, if one thinks well to put a few plants, they may be lifted from the borders and placed in pots with but little care, or, perhaps, for the loss of a few of the lower leaves. There are many varieties of merit that will bloom in the open from August to October without the aid of glass, and I give here with a short list of the sorts that I have proved as useful in a town as in a country garden.

LARGE-FLOWERING. — Albert Chanson, orange-red, tipped yellow; Edith Synn, pinkish-purple; Ivy Sterk, orange-yellow; Harvest Home, bronzy-red; Incomparable, pure white; A. Thomas, chestnut-red, golden reverse; Louis Lemaire, rosy-bronze; Mme. Carneaux, white, tinted bluish; Mme. Dea-grange, creamy-white; Mrs. Hawkins, golden-yellow; Mme. Marie Masse, lilac-maroon; de Precoces, dark crimson; Ryecroft, golden-yellow; Ryecroft Scarlet, reddish-pink; cotte: Queen of Earlies, white; Thos. Bull, deep orange; Vesuvius, red; Notaire Grand pink.

EARLY POMPONS.—Little Bob, small crimson; Mrs. Cullingford, white; Piercy's Scodling, orange-yellow; L'Ami Conderchet, primrose; Crimson Precocite, crimson; Lacintha, lilac-pink; Lyon, rosy-purple; Rose Wells, deep pink; Toreador, roddish-bronze; St. Croix, lilac; Mme. E. Lefort, orange and white; Martinmas, light pink. W. F. Bull.

An old Chrysanthemum—Julie Lagravère.—The reflexed Chrysanthemums are few in number when compared with the Japanese varieties, but one of the oldest and brightest sorts has outlived many in the latter class—viz., Julie Lagravère. It is a good dark crimson, not a large flower by any means, but rich in colour; height about 4 feet, and retains its foliage well to the base. As a rather late variety it is still to be commended, and with those who grow for home decoration only, it still finds favour.—TOWNSMAN.

Chrysanthemum Mychett Pink.—This early-flowering variety has surprised many growers with the beauty of its display. If I remember rightly, a few plants were placed before the floral committee of the National Chrysanthemum Society late in September last, and so much were they admired that a first-class certificate was readily granted. I have several excellent plants, and each one is now freely studded with chaste blossoms of a silvery-pink colour. The plant has a dwarf and sturdy habit of growth, and, what is of importance, each blossom is developed on a

plendid length of footstalk. Some of the flowers were well developed in the latter half of July, and at the time of writing (August 13) there is a fine display.—E. G.

OUTDOOR PLANTS.

IRIS GATESI IN A DEVONSHIRE GARDEN.

I do not wonder at the enthusiasm of the late Rev. H. Ewbank in regard to "Cushion" Irises, but I fear, even for them, I could not take the trouble that seems necessary with most growers. Fortunately, I am not put to the test, as here only treat them like ordinary Irises. No protection is given against autumn rain or winter cold. I flowered *I. Susinna* two years in succession before I even knew that this family of

Bud, when it broke from the sheath, 6½ inches from tip to base of standards; the open flower 18 inches from top of one standard to the other. Each standard was 6 inches across. These standards were not held erect, as in *I. Susinna*, but spread out, as shown in the illustration. The colour is silvery-fawn, with pale purple reticulations, the base of standards and falls being pale purple, the "lip" on the falls being fawn, and the great cushion of hairs by it, dark fawn. I am going to try a good many varieties this autumn in a special bed, but cultivated on the same lines.

A. BAYLTON, *Dawlish, S. Devon.*

HARDY AUTUMN-FLOWERING PLANTS.

ARTICLES have already appeared treating of the best hardy plants for the open border during the

which condition they flower most abundantly—the force exerted by the expanding buds generally breaks the pots if these are not bound round with copper wire. At the advent of frost, the plants should be removed under shelter, and very sparingly watered until they commence to make growth in the spring. There are a white form of *Acrapantus umbellatus*, and also a distinct white-flowered species, although this is not recognised in horticultural dictionaries. The latter is deciduous, whereas the type is not, and bears taller flower-umbels. Both the white-flowered African Lilies are perfectly hardy in the south-west.

ANEMONE JAPONICA.—The well-known Japanese Anemone is met with in three colours—namely, white, flesh-pink, and magenta, the last being a tint that should never be admitted into the garden. *Honorine Jobert* is a beautiful white variety, and, when at its best, reaches a height of 5 feet and flowers profusely. Newer forms are *Lady Ardlinun*, *Lord Ardlinun*, and *Whirlwind*, the two last being semi double.

PERENNIAL ASTERS OR MICHAELMAS DAISIES.—These charming plants are the mainstay of the autumn garden, the different species blooming for a period of considerably over three months. The earliest to flower is *A. Amellus*, of which species *A. Amellus bos-sarabicus* is an excellent large-flowered form bearing violet-blue blossoms. It often commences to flower at the end of July, and remains in bloom for many weeks. It is comparatively dwarf, and has not the spreading habit that renders so many of this genus unsuited for a small garden. The last to flower is the handsome *A. grandiflorus*, which is rarely in bloom before the end of October or beginning of November, a date which makes its culture inexpedient in cold districts. It bears very large flowers of a deep purple hue with golden centres, and is extremely decorative when in full bloom. It may be lifted carefully and potted when the buds are formed, and will then expand its blossoms under glass. Other good varieties are *A. neriis*, lilac-purple, forming a sheaf of flower; *Esme*, a dense bush with white flowers of the size of a florin; *A. brivigatus*, rosy; *A. patons*, sky-blue; *A. cricoides*, bearing a profusion of tiny white Daisy-like flowers; and *A. (Chrysocoma) linosyris*, a British plant commonly known as Goldlocks, but valuable for its dense corymbs of bright yellow flowers. All the foregoing are dwarf varieties, rarely exceeding 2 feet in height. *A. cordifolius* is a most graceful plant. Photograph, with small lavender flowers, is, perhaps, the best variety. *A. Shortii*, bearing sprays of bright lilac flowers, is also particularly good. These two generally reach a height of between 3 feet and 4 feet. *Perry's Pink*, producing large bright pink flowers is very distinct and ornamental, and grows to the same height. Of the Novio-Belgii section, *Archer Hind*, soft blue, *Harpur-Crewe* and *Purity*, white, and *Robert Parker*, lavender, are well worth growing. They are mostly tall growers, the last named sometimes reaching a height of 7 feet. *A. laevis Areturus* is a handsome plant with black stems and lilac flowers, with a suspicion of rose, and *A. puniceus pulcherrimus* is a noble species and a very vigorous grower, attaining a height of over 6 feet. Every spray of the plant is thickly covered with flesh-tinted flowers, which become white with age. Of the Novio-Anglic section, *Melpemone*, purple, and *Robert Parker*, rose coloured, are the best. *Boltonia asteroides* and *Edelweiss* are two Aster-like plants, natives of North America. The former bears flesh-coloured flowers, and the latter lavender.

Iris Gatesi in a Devonshire garden. From a photograph sent by Mrs. A. L. Baylton, Dawlish.

is was difficult to flower, but after reading the article in the spring journal of the Horticultural Society, I gave my Cushion Irises a little attention. They were planted in a border facing S.W., but getting all the S. sun. After a week's rain one hot day will parch the soil, which is new red sandstone, and is further dried by the roots of a huge Laurel hedge that makes the N.E. protection. I scraped away some soil (I should say the rhizomes are not on the surface but planted like an ordinary plant), and gave each of them about a pint of crushed mortar, about a tablespoonful of bone-meal, and about a teaspoonful of alum. I had no guide to quantities, but the illustration shows that I was not far wrong. When *I. Susinna* flowered in the beginning of June the bloom was far larger than before, but this one, *I. Gatesi*, is a giant. I do not know the ordinary size of the flower of this Iris, and should like to know. The measurements were

spring and summer months. The following notes will be confined to plants flowering from the commencement of August until the close of the year. Some of these, though hardy in the south-west, even when left unprotected during the hardest winters, need tub-culture or lifting before the advent of severe frost in colder localities; but, as many of them are indispensable for autumnal effect in the border, they are included in this article. **ACRAPANTHUS UMBELLATUS.**—This handsome plant, a native of the Cape of Good Hope, is one of the most decorative of autumn-flowering subjects. In favoured spots in the south-west it succeeds admirably planted permanently in the open, producing its tall blue flower-umbels in quantity year after year. In colder districts it creates a telling effect if grown in large pots or tubs and placed in the open during the winter months. Tub-culture is preferable to pots, as when the plants become pot-bound, they

two generally reach a height of between 3 feet and 4 feet. *Perry's Pink*, producing large bright pink flowers is very distinct and ornamental, and grows to the same height. Of the Novio-Belgii section, *Archer Hind*, soft blue, *Harpur-Crewe* and *Purity*, white, and *Robert Parker*, lavender, are well worth growing. They are mostly tall growers, the last named sometimes reaching a height of 7 feet. *A. laevis Areturus* is a handsome plant with black stems and lilac flowers, with a suspicion of rose, and *A. puniceus pulcherrimus* is a noble species and a very vigorous grower, attaining a height of over 6 feet. Every spray of the plant is thickly covered with flesh-tinted flowers, which become white with age. Of the Novio-Anglic section, *Melpemone*, purple, and *Robert Parker*, rose coloured, are the best. *Boltonia asteroides* and *Edelweiss* are two Aster-like plants, natives of North America. The former bears flesh-coloured flowers, and the latter lavender.

CANNAS.—Since the raising of the new large-flowered Cannas, these plants have become most admirable subjects for the autumn garden. In the south-west they may be allowed to remain undisturbed in the beds through the winter, but in more northern districts they must be lifted and housed like Dahlias, and started in heat in the spring. Of the Crozy Cannas, which are comparatively dwarf, the following are good varieties: Beauté Poitevine, scarlet; President McKinley, vivid vermilion; Duke of Marlborough, deep crimson; Aug. Chantin, orange-pink; Annie J. Chretien, flesh-pink; Secretary Chabanne, orange; Lighthouse, yellow; Queen Charlotte, scarlet with broad yellow margin; Paul Meylan, buff with narrow yellow border; Fol. Bertius Brunner, very large yellow with small red spots; Comte de Bouchard, yellow heavily mottled with crimson; and Mme. Pichon, yellow with centre of petals splashed red. Of the Italian Cannas, which grow to a great height and bear flowers from 4 inches to 6 inches in diameter, good varieties are Allemanina, America, Italia, and Pluto. The far older Canna, Ehemanni iridiflora, with its great, Musa-like leaves and slightly drooping scape of rose-crises flowers, is also very beautiful, and should not be omitted.

CHRYSANTHEMUM MAXIMUM, with its large, Daisy-like flowers, is a well-known autumn bloomer. Of late, dwarf varieties, more free flowering in habit and bearing larger blooms, have been raised, which are superior to the type.

COREOPSIS GRANDIFLORA, though commencing to flower early in the summer, often continues its display through the entire month of August.

CRINUMS.—These noble Cape bulbs are perfectly hardy in the south-west, and if planted at sufficient depth and mulched during the winter would doubtless prove so further north. At any rate, they are worth a trial. *C. cupense*, or *longifolium*, is the best known, but cannot compare with *C. Powellii* and its variety *C. Powellii alium*, *C. Moorei*, and *C. Moorei alium*, the latter known on the Continent as *C. Schmidtii* or *C. Yemensis*. When in flower these Crinums, with their tall bloom-scapes bearing several giant blossoms, make a splendid display in a well-backed border.

DAHLIAS are too well known to be dealt with at length, but it may be said that no autumn garden is complete without them. For decorative effect the Cactus varieties take the precedence, but care should be bestowed on the selection, and only those which throw the flowers well above the foliage should be ordered. A selection made at a flower show, where the individual blooms are displayed on stands, is certain to be unsatisfactory, as many of the varieties that produce the most perfect blossoms bear them hidden by the foliage, and are, therefore, utterly useless for the embellishment of the border. Dahlia tubers must be lifted after the first frost and kept in a dry cellar or other frost-proof structure until the spring, when they should be started in heat.

GALGEEA.—The type which bears rose-lilac Pea-shaped flowers and its white form are excellent border plants, forming dense bushes 4 feet or so in height, smothered in bloom-racemes.

GLADIOLUS.—The common scarlet *G. Breuchleyensis* is amongst the most effective of border plants, while the newer *G. Childsi*, *G. nanceianus*, and *Lemoine's* hybrids bear wonderfully large and handsome flowers. The foregoing and the *O. gandavensis* section may be left undisturbed in the ground through the winter in favoured localities, but, generally speaking, it is safer to lift them when the foliage withers and to replant in March.

HELIANTHUS.—The perennial Sunflowers make a brave show in the autumn with their bright yellow blossoms. *H. multiflorus* and its double variety *Soleil d'Or* are the most generally cultivated forms, but there are other species and varieties that are of greater merit. Amongst these may be named *H. rigidus* Miss Mellish, *H. latiflorus*, and the new *H. G. Moon*. Other good species are *H. giganteus* and *H. orgyalis*, both of which attain a height of 10 feet.

LOBELIA CARDINALIS.—This and *L. fulgens*, with their glowing crimson flower-spikes, are without peers for brilliancy of effect. In damp

holding soil they take no harm during the winter in the open bed, even if exposed to 20 degs. of frost. In light soil they often fail, the crowns rotting in the winter. Where this is found to be the case, the clumps should be lifted when the flower-stems wither, packed closely together in boxes, with a little dry earth or Cocoa-nut-fibre shaken in between them, and kept in frames until the spring, when they may be divided, started into growth, and replanted. These Lobelias are easily raised from seed, and, where they are found to be liable to winter failure, seedlings should be raised annually from home-saved seed.

KNIPHOFIA OR TRITOMA.—The popular Red-hot Poker or Torch Lily, with its glowing spires of bloom, is an especially effective autumn subject. Of late years numerous new species have been introduced to supplement the old *K. Uvaria*, many of which are desirable. Kniphofias require a warm situation and porous soil which does not retain moisture in the winter.

PHYSA LIS (Winter Cherry).—*P. Alkekengi* is a very old garden plant, having been introduced over 300 years ago. Its orange-scarlet bladder-like enclosure the fruit are very decorative in the garden, and still more so for winter indoor decoration. It is entirely surpassed, however, by *P. Franchetti*, whose great balloons are sometimes 8 inches in circumference. Both are perfectly hardy and increase rapidly.

PYRTHRUM ELIGINOSUM.—Many who have but slight knowledge of flowers class this with the Michaelmas Daisies, which it somewhat resembles in manner of growth. Its large,

The Red Flax (*Linum grandiflorum*).

white, sterry flowers, with their narrow rays, are very graceful, and a fine plant in full bloom presents a charming picture.

SENECIO PULCHER.—This plant grows to a height of 3 feet, and bears large flowers of a deep magenta tint. Those who dislike that colour should eliminate it from their list of desirable autumn flowers. The three following plants may be termed winter flowerers:

SCHIZOSTYLIS COCCINEA is a small bulbous plant, growing 18 inches in height, and bearing scapes of bright crimson flowers. It blooms from October to December if the weather be mild, and is most useful for indoor decoration.

IRIS STILOSA.—This lovely Iris and its white variety bear their blossoms from the end of October until April. Large plants produce a continuous supply of flowers, which should be picked in the bud stage and expended indoors, where they are always welcome, being deliciously fragrant as well as very beautiful. The plant does best on a dry bank of light soil, and in cold districts should be planted against a wall in porous compost with rapid drainage, and should be sheltered from cutting winds.

CHRISTMAS ROSES.—These chaste flowers, coming, as they do, in mid-winter, are of inestimable value. The first to flower is the giant *Helleborus altifolius* or *maximus*, which commences to bloom in November. Other grand varieties are *H. juvernisi* (St. Brigid's Christmas Rose), *H. major*, Bath variety, the Riverston variety, the Brockhurst variety, Mme. Fourcade, and the Manchester and

Scotch varieties of *H. angustifolius*. Christmas Roses require deep, shaded, well-manured soil and a partially sheltered position, where they are not burnt up by the summer sun. In dry weather they should receive copious supplies of water. S. W. F.

NOTES AND REPLIES.

Raising Zinnias.—I have seen in public gardens in France some exceedingly large Zinnia-bushes quite 3 feet or 3 feet through, and many blossoms. I was told the plants were raised in the previous autumn and kept potted on. Can any reader tell me if this is the case? I have every convenience—warm-house, cool-house, frames, and cold.—T. H. H.

Solidago Shortii.—"W. F." on page 310, condemns *Solidago*. Has he ever grown *Solidago Shortii*? This is one of the loveliest of all autumn-flowering plants, and quite distinct from every other variety. Where twelve autumn-flowering plants are wanted this should be one.—A. J. P., *Winchmore Hill*, N.

Tufted Pansy Cottage Maid.—Another season has again shown the high quality of this. The variety under notice is of the same character, in so far as the flower is concerned, as Countess of Kintore. As regards its habit, it is superior to others of the same type, and it also flowers freely. It is one of the earliest in the spring to bloom, and the autumn is well advanced before its display ceases. Its colour may be described as alternately marked purplish-violet and pale lavender, sometimes almost white.—E. G.

Primroses.—Most charming of spring flowers are the Primroses, and it is questionable if any are more beautiful than the wild blossoms of our fields and woodlands. In moving some clumps a few months ago I took up a quantity of self-sown young plants, and these were planted out by themselves and have now (the beginning of August) attained a good size, and I purpose planting them under a hedgerow in the garden. Few grow the common field sorts, perhaps because they are common, but in spring they flower freely in the garden with finer blooms, and on banks and hedgerows have a pretty effect. Now is the time to plant.—WOODBASTWICK.

Common Musk in open border.—During this season I have been much pleased with a large patch of Musk growing in a shady border here in kitchen garden. Some two years ago this was thrown out with some soil from the potting bench. On the wall above Wallflowers are growing; the seeds drop and sow themselves amongst the Musk roots. During this summer the Musk has found the Wallflower stems a good support, and has climbed up a foot or more, spreading all over the Wallflowers. For many weeks this was a sheet of yellow, several feet across, and nothing could be more lovely. The Musk roots get no protection in winter or assistance in any way. Musk may be used as a carpet to many things with the best results.—J. C.

Hardy white flowers.—I shall be much obliged if you will give me a list in GARDENING of the best hardy white flowers for the various months? I want kinds in which the blossoms last well when cut. The soil is light and sandy. Will you also tell me which of them can be raised from seed, and the proper time to sow it?—S. E. F.

[The number of pure white hardy flowers is not great, but the following are among the most useful: In April and May *Narcissus poeticus* and its varieties, and in the latter month *Anemone sylvestris** and *A. s. fl.-pl.* *Arabis albidia fl.-pl.*, a new and valuable plant for cutting; in early June *Achillea monogolica*, and in the latter part of the same month single white *Pyrethrums*, also *Achillea ptarmica fl.-pl.* and the variety known as the Pearl. In the same period, too, are the several varieties of *Campanula persicifolia*, all good and distinct. Then *Galega officinalis alba* for June and July, and *Galtonia candicans* in the latter, though perhaps the most valuable plant at this time is the white perennial *Pes* (*Lathyrus latifolius albus**), and with the new kind now being distributed—viz., *L. latifolius albus grandiflorus*—make a fine pair. At this time also flower the many kinds of white perennial *Marguerites* or *Lencanthemums*, of which there are quite a dozen that vary but little in size and form and in other ways. In autumn white flowered subjects are not plentiful, but the best plant undoubtedly is *Anemone japonica alba*, and there are white forms of some of the Michaelmas Daisies. Those marked with an asterisk may be obtained from seeds, but it is often quite a slow method and not always satisfactory.]

THE DWARF FLAXES.

One character which the *Linums* present is a lightness and elegance of contour, to which the usually narrow leaves, slender stems, and delicate peduncles which support the individual flowers, all tend to contribute. This speciality is equally patent to those who are familiar with our commercial Flax (*Linum usitatissimum*), whose cultivation extends over large fields in some parts of the country, and where, when in full blossom, such fields can be compared to nothing more appropriate than an azure sea, varied only in its lights and shades as it is gently rippled by the summer's breeze, or in the condition with which most people are familiar, as cultivated in its perennial form (*L. perenne*) as a border plant, possessing with neatness of habit a long continued blooming season.

ALPINE FLAX (*L. alpinum*).—This Flax, growing only from 3 inches to 8 inches high,

grown as a frame and greenhouse plant, but should be tried everywhere in warm spots on dry borders, banks, or rockwork. It begins to bloom in early summer.

YELLOW HERBACEOUS FLAX (*L. campanulatum*).—An herbaceous plant, with golden-yellow flowers in corymbs on stems from 12 inches to 18 inches high, distinct from anything else in cultivation, and well worthy of a place in collections of alpine and herbaceous plants. A native of the South of Europe, flowering in summer and flourishing freely in dry soil on the warm sides of banks or rockwork, and propagated by seeds. This is a very distinct plant from that usually grown as *L. flavum*, the leaves much narrower, more stoutly set, the plant altogether dwarfer and neater in habit, and seedling more freely. It also flowers more freely on much shorter stems.

THE TAURIAN YELLOW FLAX (*Linum flavum*).—For many years *L. campanulatum* was known by this name, and so generally had the mis-

blossoms. By successive sowings it may be had in bloom from May till October. Seed sown in autumn will give plants for spring blooming, and sowings made from March to June will yield a display through the summer and autumn. By sowing seeds in pots in good rich soil in summer, and plunging in a sunny border with plenty of water, plants may be obtained for the greenhouse or window during October and November.

NEW ZEALAND FLAX (*L. monogynum*).—A beautiful kind with large pure white blossoms opening in summer. It grows about 1½ feet high in good light soil, and its neat and slender habit renders it particularly pleasing for the borders of the rock-garden or for pot culture. It may be readily increased by seed or division; it is hardy in the more temperate parts of England, but in the colder districts is said to require some protection. *L. candidissimum* is a finer and hardier variety. Both are natives of New Zealand.

The Narbonne Flax (*Linum narbonneuse*). From a photograph sent by Mr. G. Weir-Cosens, Aberystwyth.

bears very large dark-blue flowers in summer. It is easily distinguished by its external sepals being acuminately pointed, and the internal ones obtusely pointed. A charming rock-plant, native of the Alps, Pyrenees, and many hilly parts of Europe, thriving well in warm well-drained spots on rockwork, in a mixture of sandy loam and peat. There are several varieties; *L. austriacum* is intimately related to it, and scarcely sufficiently distinct from a garden point of view.

EVERGREEN FLAX (*L. arboreum*).—This is a neat, glaucous-leaved, dwarf, spreading shrub, with a profusion of clear handsome large yellow flowers, an inch and a-half across. Although said to be rather tender in the colder parts of the country, it thrives well in others in the open air, even as a border-plant, and in all is well worthy of a position on rockwork. A native of hilly parts of South-Eastern Europe, Asia Minor, and North Africa; usually propagated by cuttings. It is sometimes

nomer become established, that even at the present day the mistake is frequently perpetrated; nevertheless the two plants are amply distinct. This species is an herbaceous plant in the strictest sense of the word, dying down annually to a short, woody subterranean root-stock, from which year by year arise several erect flowering stems, sharply angled and clothed with dark, olive-green foliage, ovate, slightly cordate at the base and gradually narrowing upwards; the flowers, which are produced in August, being of a rich golden-yellow. It is perfectly hardy, and forms a handsome and long-lived herbaceous plant, and should certainly receive a larger meed of attention than it has hitherto done. By some authors it is named *L. tauricum*, being abundant in the Taurian Mountains, and, in fact, is generally met with in the upland meadows in Eastern Europe.

RED FLAX (*L. grandiflorum*) is a showy hardy annual from Algeria, with deep red

THE NARBONNE FLAX (*Linum narbonneuse*).—A beautiful and distinct sort, bearing during the summer months a profusion of large, light sky-blue flowers, with violet-blue veins. A fine ornament for borders, the flower-garden, or the lower flanks of rockwork, as may be seen by our illustration, on rich, light soil, forming lovely masses of blue from 15 inches to 20 inches high. A native of Southern Europe, distinguished from its relatives by its sepals tapering to a long point, its anthers being three times as long as broad, its long thread-like stigmas, and its large flowers.

PERENNIAL FLAX (*Linum perenne*).—A plant found in some parts of Britain, particularly in the Eastern counties, but very rare. Usually grows in dense tufts from 12 inches to 18 inches high, with bright cobalt-blue flowers more than an inch in diameter, the stamens in some being longer than the styles, in others shorter, the petals overlapping each other at the edges. *L. perenne album* is also an ornamental plant,

and there is also a variety with blue flowers variegated with white, known in gardens as *L. Lewisii variegatum*, but this marking is not very conspicuous or constant. *L. sibiricum* and *L. provinciale* are also included under perenne. Of very easy culture in common garden soil, it is a useful border plant, and may also be used in rough rocky places.

WHITE ROCK FLAX (*L. subuloides*) is a dwarf half-shrubby species, essentially a rock garden plant; its flowers, white with a purplish eye, reminding one of some of our creeping white Phloxes. In the rock garden, in a well-exposed sunny nook, the plant is hardy, and trails over stones, flowering abundantly. It produces seeds rarely, so that it must be increased by cuttings of the short shoots taken off about midsummer; these will strike freely, and make vigorous plants when potted in the following spring. *L. viscosum*, with pink flowers, is a closely allied plant. Mountains of Europe.

VEGETABLES.

POTATOES.

In this part of Surrey Potatoes vary wonderfully in appearance. Here and there one comes across breadths of Early Puritan and Up-to-Date, the two varieties most favoured about here, in the finest possible condition; but in a general way the growth is not uniform, and in many places the tubers made about a foot of growth and have since remained absolutely stationary. I have a breadth of Puritan, the hauls of which is now (August 2nd) no higher than it was a month ago, and the leaves look as if they had been scorched by a fire. The sets were put in in good time, the ground was deeply dug, laid up rough, and thoroughly sweetened. The sets looked firm and good when planted, but as they came from plants that were much checked in growth by the fierce heat and drought of last summer, they probably did not properly mature. Growing close to them is a breadth of another kind which leaves nothing to be desired in the matter of health and vigour. In this instance the sets came from plants that made good healthy growth last year. I would advise Potato-growers generally to save no seed from plants that exhibit lack of vigour this season, or the results may be equally bad next year. It is better to have a complete change of seed every now and then, taking care that it comes from land which is quite different in character from that which the grower himself has to deal with. Where the soil is sandy the seed should come from heavy loam, and *vice versa*. It is said that change of seed is as good as a coat of manure, and, to a certain extent, I believe this to be correct.

That old favourite, Magnum Bonum, seems to have gone out of favour in this part of Surrey. Potato-growers found that Up-to-Date did remarkably well in the very hot, dry seasons experienced of late—in fact, better than any other main-crop kind that had been grown for profit on the light, loamy, and sandy Surrey soils. Nothing, however, seems to be known with respect to the disease-resisting properties of this Potato. Surely it came into favour the seasons have been dry and hot, so that there has been no opportunity of seeing how this Potato can stand against a period of the warm, wet weather that brings on disease. There are, moreover, signs that Up-to-Date, in spite of its robust habit, has an element of weakness in its constitution. A neighbour of mine, who grows for market, could not sell a sixth part of his crop last season. The tubers were large, and, to all appearance, sound, but when cut through, black specks were to be seen in the flesh. Naturally, when boiled they had not a very attractive appearance, and it is doubtful if they were good for food. A few years ago the same disease appeared in Magnum Bonum, and now this Potato is so unreliable that in many localities it has dropped out of cultivation. The same thing has occurred with Supreme, Beauty of Hebron, Early Rose, White Elephant, etc. They were good in their time, but they have had their day, and it will probably be the same with Puritan, Up-to-Date, and some others that we have been

relying on of late. Fortunately new varieties are constantly being raised, and Potatoes being grown to such a large extent now-a-days, their merits are more quickly recognised than would have been the case twenty years ago.

Growers for market are aware that they must cultivate the best and most reliable kinds only, so that any new variety is sure of a fair trial. I am this season trying a new kind called The Crofter, which is highly recommended by a well-known Scotch firm, as a main-crop variety. It has been favourably reported on by growers throughout the country, and is said by the introducers to be disease-proof. I am growing it along with Magna Bonum, which it much resembles in leaf, habit of growth, and colour of bloom; but the difference in strength is remarkable. The tubers are more round and the quality is good. I should say that Magna Bonum is one of the parents, so that one may easily credit it with possessing the disease-resisting properties claimed for it. Another variety that will probably be much grown, is Sutton's Seedling. It is of free, vigorous growth, and crops heavily. I recently saw a field partly planted with it and partly with Up-to-Date, and the difference in favour of Sutton's Seedling will, judging from appearance, probably be from four to six tons per acre.

Disease, I am sorry to say, has appeared, and since writing the above some of the most promising breadths have been badly attacked. Frequent thunderstorms, with drizzling rains that keep the leaves wet all through the night, will, if the temperature is sufficiently high, cause sad havoc in the course of a couple of weeks. In the case of varieties that do not possess disease-resisting powers, it is best to cut off the hauls as soon as the scourge makes its appearance. From the time the leaves are affected the tubers cease to swell, so that they may just as well be cut off, and save whatever crop there may be. J. C., *Byfleet*.

GRASS FROM THE LAWN MOWER.

OFTEN this is regarded as material of but little value; perhaps where the lawn is of small extent it may be so, but it must be a poor garden that could not find a use for lawn Grass fresh from the week's mowing. A purpose for which we invariably employ a good deal of short Grass is as a mulch to something it is deemed necessary to protect from the direct rays of the sun. Celery trenches afford an illustration for its use. When small plants of this are freshly put out, and the weather sets in bright and warm, the soil needs frequent watering to keep the surface moist, and, as Celery plants are soon injured by drought, and there is not so much time for watering, a light covering of lawn Grass saves labour, while it preserves a greater equality of moisture about the roots. We have known instances where Celery, after being planted, has gone through the season without any help from watering save that given to settle the soil down in the first instance. We are not so fortunate as this, the nature of the soil demanding more effort. Celery when neglected in the matter of root moisture is much inclined to bolting. Some objection may be raised against the use of Grass because it is not lasting. True, the action of sun and air quickly reduces its bulk; but as the mowing has to be done often, so can additions be given to surfaces already treated. Tomatoes against hot, sunny walls are benefited by a surface mulching, for, if water cannot be applied often, the soil gets hot and very dry, and consequently plants languish instead of progress. Unless afforded sufficient moisture at the roots, these set their fruits indifferently. During hot summer weather Grass and Clover seeds mature sufficiently to vegetate from one mowing day to another. This may be regarded as a nuisance, which, should wet weather ensue, may be the case; but in hot weather this growth is easily destroyed by mowing it on a sunny day. In the Celery trench we have not found Grass and Clover seeds give rise to any such troubles. If no use can be put to Grass in a green state, it can be collected in a heap week by week, and when decayed employed either alone or in conjunction with manure for digging or trenching into the garden in winter. To this again objection may be raised, for, if used too freely, it has been found to render soil

heavy or rather close in texture, but this only when employed alone. Unless other material can be jointly used, it is not advisable to dig rotten Grass into heavy land. W. S.

AUTUMN-SOWN CAULIFLOWER.

MUCH has been written from time to time as to the best time to sow Cauliflowers. Some growers say it is unnecessary to sow in autumn. This may do where there is plenty of glass, such as pits or handlights to grow the plants in. I have seen Cauliflowers sown under glass at the beginning of the year brought forward by planting on raised beds under frames, these being ready to cut as soon as autumn-grown plants. During the past thirty years I have tried many methods, and consider that it depends more on the accommodation than anything else as to the time the seed should be sown. To have early heads so that no break comes between the late Broccoli and these, and if they have to be brought on principally in the open, then no method equals sowing in autumn, according to the district the grower resides in. Speaking generally, from the 20th of August till the first week in September is a suitable time. I want from 800 to 1,000 plants, and not having glass to grow them under I have tried various ways. I sowed about the time mentioned, in an open position, and when the autumn advances the largest are planted at the foot of a wall, where they remain unprotected through the winter. I seldom lose any, and in this position I cut the first heads. This year good heads are ready by the 20th of May. Another batch is potted into sixty pots. These are planted out early in the year under handlights, having been wintered in a frame, and should those under the wall have suffered, these take their place. By planting these out before they get pot-bound, and giving shelter for a time, they are only a few days later than those at the foot of the wall.

The major portion of this autumn-sowing is pricked out into boxes and wintered with these in pots in frames. These are planted out as soon as the weather permits, in lightly-manured and deeply worked soil. Care is taken to lift them out of the boxes with a ball of soil, and although these stand still for a time they grow rapidly when warm weather comes, and follow the others in close succession. I have often had many of my plants destroyed by rats and mice eating out the centres when covered up in frames. This has made me cautious, and to provide against this I sow a box of seed at the end of October or in the first week in November, keeping it on a shelf in a cold Peach-house. These seedlings are pricked out into other boxes early in January, and brought on in the same position. As soon as the days lengthen they make rapid growth, and are hardened off with those wintered in frames. When planted out there is no difference in the time they come into use. I much prefer this way to sowing in boxes or on a hot-bed in spring, seeing the plants do not go black-legged and are more hardy. Another way I have adopted is to sow a pinch of seed with Lettuces and Radishes on the soil I cover the Asparagus roots with when put in to force in cold house at the end of January. These I allow to remain till large enough to plant out in open ground. The forcing types, as they are termed, are not suitable for autumn-sowing, as frequently a large percentage buttons in spring. I prefer a good selection of Erfurt or a dwarf selection of Early London. Some twenty-five years ago it was possible to obtain a good dwarf strain of Walcheren, which was hard to beat. J. Crook.

NOTES AND REPLIES.

Cucumbers failing.—My Cucumbers these last few summers have been a failure, having a kind of disease upon them. It takes the form of dots of crystal or jelly, drying away and leaving black spots. If you could give me any information I should be much obliged. The vines appear quite healthy and strong. I have a nice house of Cucumbers going off now; one house I have had to destroy.—S. PINK.

[It is very difficult to assign any reason for the failure, seeing you give us no particulars as to culture to help guide us. From the specimens you send we should imagine that they are kept too cold, and in this way have received a check. Cucumbers want a good steady

bottom-heat of 80 degrees with a top-heat of 70 degrees at night, rising during the day so as to permit of free ventilation to ensure hardy strong leafage. The soil should be good loam with plenty of fibre in it, in order to cause a hard and firm growth.]

Improper schedule terms.—In connection with the drafting of country show prize schedules how much tendency is there seen to use terms that are both improper and useless, and which necessitate so much additional expense in printing! Why will committees continue to call Celery as "sticks?" No term can be more absurd. The term "stick" is also commonly applied to Rhubarb, which should be called "stem." Cauliflowers and Cabbages are termed "heads"—needless appellations. Beets are called Beetroots; yet Carrots are not called Carrot-roots. The term "French," as applied to Dwarf Kidney Beans, is improper, as they are not French at all. They should be classed as Dwarf Kidney. It is common practice to have classes for "round" and "Kidney" Potatoes. These distinctions are now almost obliterated, one running into the other. The best plan is to have "white" and "coloured" classes only. Kinds and varieties get terribly

of this fact to obtain many crops off the same area of land every year, and their vegetables and salads are appreciated at their true value. Large size is not with them or their patrons so essential as are succulence and good flavour.—*Field.*

FRUIT.

CORDON-TRAINED FRUIT-TREES.

The cordon form of training fruit-trees is peculiarly well adapted for certain purposes, particularly Pears on walls. In this case its advantages are manifest; the trees not only coming into bearing more quickly than when fan-trained, but one is able to grow a tolerably large collection of varieties in a limited space. The old adage, "Those who plant Pears, plant for their heirs," is no longer applicable to this improved form of fruit culture. In saying this, I do not mean that cordon-trained trees are more certain bearers than others, because they are not. Our climate is such that no form of trained tree escapes its influence. Therefore, as regards securing regular crops, one form of training is about as good as

the branches; but when judiciously handled, the Pear-stock can be made to produce a fruitful tree nearly as soon as the Quince. The direction in which the branches are to be trained is a point on which there is some difference of opinion, some preferring the oblique, and others vertical training. The oblique form has, however, a better appearance than the vertical when the trees are trained against walls.

PRUNING.—In regard to pruning this form of tree, I do not agree with persistent pruning. I am satisfied that that system does not increase fruitfulness. I go over the trees twice during the summer with pruning nippers. Early in July the leading shoots are nailed in, and all the others are shortened back, so as to leave about 1 foot in length of the young wood. In the case of vigorous trees they soon rush into growth again, and send out two or three young shoots from the points of the young wood that was headed back. By doing this we preserve the buds close home, so to speak, intact, and at the same time make the appearance of the trees presentable. About the end of August I again go over them. This time I cut the shoots that before were topped back to a spur. If after

A wall of cordon-trained fruit trees. From a photograph sent by Mrs. Readman, Mynde Park, Hereford.

mixed. They mean such diverse things. A "kind" means Potatoes, Cabbages, Peas, Carrots, Onions, and so on. A variety is any one of these named, or of any other kind of fruit, flower, or vegetable.—A. D.

Vegetables at their best.—Those who appreciate good vegetables should be careful to have them gathered when young and tender, instead of leaving them, as many do, until they are tough and staid. Most gardeners prefer size or more bulk to quality and flavour, and are inclined to leave vegetables ungathered until past their best. This is especially true of Peas, Beans, Vegetable Marrows, and even with the various phases of the Cabbage family, none of which are so delicate and tender as when fresh and young. Vegetable Marrows and Peas are really marrowlike when young, but the former might as well be Turnips when full-sized or when old. With nearly all the root crops it is the same, and to appreciate such vegetables as Shorthorn Carrots, Turnips, or salad vegetables like Lettuce, Endive, Radishes, and Cucumbers, they must be quickly grown and gathered young. The same is true of Asparagus, Seakale, Rhubarb, and many other things never so good as when forced quickly and eaten when quite young. The French market gardeners take advantage

of another; but the fact that the trees come into bearing the third and fourth year after planting, and that the cordon plan admits of a wider choice of sorts, is sufficient to stamp its merits. Even away from walls cordon-trained trees are much better than pyramids, and why they should be so is not difficult to explain. One word, in fact, clears the matter up—viz., shelter. A cordon-trained tree whose branches are not more than 18 inches from the ground gets a great deal more shelter from surrounding walls and other objects than a pyramid from 6 feet to 10 feet high; and this difference as regards shelter explains why cordon Pear-trees bear more regularly than pyramids, and the same remark is equally applicable to Apple-trees trained in the same way.

Stocks.—In the matter of stocks for cordon Pears, the character of the soil must influence the decision. In a strong soil, fairly retentive of moisture, the Quince is no doubt the best stock, as it promotes early fruit-bearing; but in other kinds of soils the Pear-stock is more reliable where a judicious system of root-pruning or lifting is practised. Many prefer the Quince as a stock where the soil suits it, and when they understand how to treat it in particular cases, on account of its reducing the vigour of

this there is any disposition in the tree to form any flower-buds on the spur, there is time enough for it to do so; but I do not pruned with the idea that I can always place a fruit-bud where it is wanted. If a tree is managed in a rational manner, that is to say, if the roots are fairly well nourished and any excess of vigour checked by judicious root-pruning, it will always produce more fruit-buds than it can mature fruit. With respect to the management of the roots of cordon trees, if they are Pear-trees on the Quince and form a single cordon, we may be sure that the soil will soon get full of roots, and that what goodness it contains will soon be exhausted. It will, therefore, be necessary to keep up fertility by rich dressings of rotten manure spread on the surface. This is best laid on now, so that the rain may wash what nutriment it contains down to the roots, and unless the soil is naturally holding in its character, trees growing on the Quince-stock will want assistance in dry weather in the way of watering. Espalier and cordon Apple and Pear-trees should be planted near the edges of walks. Plant them the same as other trees, and they will require some stakes or other supports to train the branches on. This type of tree produces very fine fruit, and is especially

useful for small gardens. On no account overcrowd the growth. Pinch off the growth with, if possible, the finger and thumb, which is better than a knife. Stopping promotes fruit-buds at the base of the spurs. There is then less need for pruning in winter. J.

NOTES AND REPLIES.

Tying up shoulders of Grapes.—There cannot be any question that the practice of shouldering up bunches of Grapes is often carried too far. Often upon entering vinerias at this season of the year after the bunches have been thinned a perfect network of string meets the eye at every turn. True, by spreading out the bunches to their fullest extent they look much larger than they otherwise would do, but after the Grapes are ripe and cut the bunches are anything but pleasing when on the dish. I do not go so far as to say that no bunches should be shouldered, as in such varieties as Barbarossa, Trebbiano, and others of that ilk, shouldering must be practised if handsome bunches are to be produced. Occasionally a few bunches of other kinds, such as Muscat of Alexandria, or even Mrs. Pince, or extra large bunches of Black Hamburgh, may be improved by a little judicious shouldering. What I like to see are nice, tapering pyramidal bunches, all ugly shoulders having been previously removed. It often takes a lot of courage to remove portions of clusters of bunches, but those growers who practise it never have any fear on this point, knowing that those portions which are removed do not add either to the symmetry of the bunches or to the look of the crop when finished. All the ugly shoulders should, of course, be removed just as the bunches are forming, thereby throwing all the strength into the main bunch. The practice I pursue with all Grapes, except in the case of extra large bunches, is not to shoulder up at all, but to merely go over the bunches just as the berries are stoning and gently raise the shoulders so as to prevent any undue binding. As the berries take on the second swelling they gradually push the shoulders upwards until these have quite a rounded appearance.—A.

Strawberries failing.—I write to ask if you can tell me the reason for failure of my Strawberries under following conditions? They were planted in 1900, and consist of three kinds: (1) St. Joseph, (2) Royal Sovereign, (3) Another red kind, name not known, and which this year gave promise of an abundant crop. In each year, however, the same thing has occurred. They have been seized with a kind of blight, which rots them very rapidly, and soon reduces them to dust. The rot is distributed over all the beds, but seems particularly rampant with the St. Joseph. I am at a loss to account for it, as the same thing has occurred in two widely differing summers—last year, hot and dry; this year, cold, and, of late, rather wet. They have had every care, and are carefully bedded with straw. The soil is stiffish clay, manured slightly each winter with a mulching of peat-Moss-litter and a little fine cinders to lighten the soil. Aspect south. If you can give me some idea as to the cause and the best remedy I shall be very much obliged.—FRANK R. DUNCKLEY.

[We cannot suggest to you any other kind of Strawberry that would be unaffected by the mildew which infests your plants each year, because they differ so materially in their constitution that it is only by actual experiment that success or failure is determined. The fact of the disease occurring in two widely differing seasons points to extremes which are known to produce the same evil—excess of soil and air humidity and drought. There is nothing that so well repays fresh ground and fresh stock as Strawberries, and we strongly advise you in the present season to procure some plants from a new source, and in the meantime provide a fresh site for them. Though Strawberries are surface rooting plants, they nevertheless require land well filled, and this, too, as deep as circumstances allow. Peat-Moss-manure is not good for all soil or crops, and the probability is it does not suit in your case. This we would advise to be discontinued, and instead use strawy manure, both for digging into the soil and for surface manuring. Probably, too, some lime and soot, applied in autumn or winter, so that the rain washes them into the soil, would benefit the plants. When well cultivated Strawberries do well on heavy ground, but the usual course of mulching with strawy manure in winter would not be the best suited in such cases. Short manure shaken out from the straw, or that which has been prepared for and produced a crop of Mushrooms, would be admirable for lightly pointing into the surface

in late autumn or winter, deferring the strowing of the bed until after the flowering period. For St. Joseph substitute St. Antoine de Padua, if you desire a perpetual variety, and procure good runners of, say, Leader, Fillbasket, and Aberdeen Favourite as a change of stock. Another suggestion we would make is to give more space between your plants. If the growth become vigorous, a distance of not less than 30 inches should be allowed between the rows, and about half the distance between the plants. If the leafage is so dense that air cannot play through it, and especially in damp weather, the fruits quickly decay in the manner

Zenobia speciosa (syn. Andromeda speciosa).

you complain of. Strawberries ought not to be allowed to stand longer than three years.]

United Horticultural Benefit and Provident Society.—The monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi-terrace, Strand, on Monday evening, August 11th. Mr. Thos. Winter presided. After the minutes of the last meeting had been read and signed, four new members were elected and one nominated. Five members were reported on the Sick Fund, and two others had been on and off the Fund since the last meeting. The Secretary was instructed to make the preliminary arrangements for the annual dinner, to be held early in October next.

TREES AND SHRUBS.

ZENOBIA SPECIOSA.

THIS is one of the most beautiful shrubs in the Heath family, about a yard high, with small roundish leaves of a pale green. In the variety pulverulenta the leaves are almost white, covered with a mealy glaucousness. The flowers, white and wax-like in form, resembling those of Lily of the Valley, come in summer in beautiful loose drooping clusters. A well-flowered specimen is most charming, and lasts for some weeks in beauty. The shrub thrives in a peaty soil or a sandy loam. It comes from the Southern United States, and is therefore not absolutely hardy. In nurseries it is known as *Andromeda cassineifolia* and *A. speciosa*, and the variety *Z. pulverulenta* as *A. dealbata* and *A. pulverulenta*.

The purple Venetian Sumach.—Many of our readers know the old Venetian Sumach, which, well grown in the open, is such a striking plant, and as hardy and long lived as striking. I had no idea when purchasing and planting this new kind of Sumach that it was so very different from the old one as I find it is. Its curious blooms are now very handsome, and I find it very distinct from the old bush. I take no trouble with it, planted on a bare, dry bank, where it certainly has no comfort beyond a full exposure to such sun as we get, and has to struggle with the weeds of the place.—W. R.

GARDEN PESTS AND FRIENDS.

Fungus on Rose-trees.—I would be much obliged if you could tell me the cause of and remedy for the disease which has attacked the leaves of the Rose, some specimens of which I enclose? Every leaf is attacked. Is it a fungus, or does it come from green-fly?—ARDREIGH.

[Your Rose leaves are attacked by a fungus, the Rose rust (*Pragmidium subcorticum*), at times a very common pest. Spraying with dilute Bordeaux mixture will check it. When the leaves fall they should be collected and burnt. Next spring, before the buds open, spray thoroughly with 2 oz. of sulphate of copper dissolved in 3 gallons of water.—G. S. S.]

Campanula failing (*Miss Wilson*).—Your Campanulas have been attacked by a fungus, very probably *Sclerotinia sclerotium*, but I cannot say for certain if this be the case. Some fungi, that which has killed your plants among the number, at a certain period of their existence become hardened, rounded, generally black masses, known as sclerotia. When in this condition it is impossible to be certain to what species they belong. You may find these sclerotia within the dead stems. Pull up and burn all the dead and infected plants.—G. S. S.

Red-spider on Violets.—I am sending you a few specimen leaves of my Violet plants, and shall be very much obliged if you can kindly tell me what is wrong with them, and what had I better do to my plants? The disease has appeared on all my two-year-old plants, and has attacked some of my other young plants in the beds near. I shall be very much obliged if you can give me any help upon this subject.—(MISS) MARY C. FRANCE.

[The Violet leaves you send are eaten up with red-spider. The only thing you can do is to syringe them with Quassia extract and soft-soap, so as to get them clean. You have allowed the plants to get very dry during the summer, hence the pest from which they are now suffering. Violets when growing in the open air must be kept well watered and mulched with rotten dung, and also syringed freely in the evening, if the weather is hot and dry.]

Thriffs.—Thriffs appeal to all who still retain an affection for old-fashioned garden flowers, and if we do not grow them to any extent ourselves, we have recollections of seeing their thick cushions covered with blossoms in not a few country gardens, so they do not call for much attention when once they have become established, and Thriffs will thrive in the poorest soil. They sometimes die off in the centre of the crowns, and to avoid this they should be pulled to pieces occasionally and divided. The young plants also bloom the best. They are nice for the rock garden, doing well in any cool niche or crevice.—TOWNSMAN.

GARDEN WORK.

Conservatory.—It will soon be time to begin reducing the growth of the climbers where they have been allowed to grow freely. They are lovely in the hot weather, but when the days are shorter they darken the house too much, and should be gradually reduced. Hard-wooded plants outside will require to be watched carefully, especially those having dense foliage, such as Hothos and Azaleas, where neglect, as regards watering, might be fatal. Passing showers do not water sufficiently plants in pots which are full of roots. Cyclamens, Primulas, and Cinerarias are growing freely now, and should not be too much shaded. It will be as well in mild, warm weather, to take the lights off when the afternoon sprinkling is given, and leave them off all night. This keeps the growth dwarf and sturdy. Chrysanthemums are growing freely now, and bud selection will, in some instances, have taken place. As a rule, the second crown-buds give the best flowers. The hunt for earwigs must be continuous. These insects are partial to certain kinds, and, if permitted, they soon destroy all prospects of good blooms on the plant they fancy. Stimulents may be given to plants which require it, but judgment is necessary, as some kinds require more nourishment than others. Roses intended for forcing should be repotted or top-dressed. The new Rose Liberty is a grand force, and is now cheap enough for all to purchase who desire a bright button-hole flower. Arum Lilies should be broken up and repotted now, if not already done, but they should be kept in the open-air as long as it is safe to do so. The lancifolium section of Lilies where brought on quite cool, will be useful in the conservatory now. We generally stand some outside in a sheltered spot on coal-ashes for late blooming. This section is a most useful one, as the bulbs will increase and flower freely from year to year, and are hardy and free from disease. A few good specimens in pots of *Bongainvillea glabra* and *Plumbago capensis* will show well in the conservatory now. The white variety of *Plumbago*, though not so popular as the blue, is still useful. The old *Pasiflora kermesina* makes a good specimen in a pot. It is a bright-flowered kind, and is easily grown. As *Fuchsias* go out of flower place them outside to ripen, and have younger plants coming on in pits, or even outside, to fill up for the autumn. Plants struck early in spring, if well grown, will be coming into bloom now. To bloom *Fuchsias* well late, they must never be allowed to get pot-bound till the plants have pretty well attained their intended size.

Ferns under glass.—We often have hot, bright days in August and September, and then a little shade will be necessary and grateful to the plants, but too much shade weakens the growth and makes the fronds too tender for floral decorations. To remedy this, shade less and ventilate more freely. Spores can be gathered from old plants which have been grown in a well ventilated house. Scarcely any plant will produce fertile seeds under unnatural conditions, and though Ferns like a subdued light they will not produce fertile spores in a hoovily shaded spot. If any repotting is required to be done—and there is always something to repot in a large collection of Ferns—it will be best to get it done before the short days come. Seedlings should be pricked off into shallow boxes as soon as they are large enough to handle, and kept in a close, shady pit for a time till growth becomes active. The best soil for Ferns is one half yellow loam and the remainder made up of peat, leaf-mould, and a dash of soot, with a free admixture of coarse, sharp sand. Very delicate species may have more fibrous peat and sand and less loam. It is not necessary to pot Ferns so firmly as one would do a Heath or Azalea, still the soil should be made reasonably firm, especially when one wants to keep the plants in as small pots as possible.

Work among Pines.—Plants which are opening fruit must be kept on the dry side at the root, but liquid manure can be given to those swelling. In the past we obtained our stimulants from the manure tank. Now various artificials are used, but even now those who

have a farmyard tank need not use artificials. A thin shade will be necessary on bright days, and a dewing over with the syringe will be beneficial twice a day to all except plants in blossom or ripening fruit. Suckers may be taken at any time when ready, and the crowns of the ripe fruit may be saved and potted if required, though suckers are generally used for increasing stock. Night temperature of fruiting-house, 70 degs.; successions, 65 degs. A little ventilation should be given when the thermometer has advanced 10 degs. in each case. In all cases bottom-heat should be maintained.

Late Melons.—Melons are always useful for dessert, and it is desirable to have them as late as possible; but it is too late to plant in frames or pits now, unless heat can be obtained from hot-water pipes in addition to that obtained from hot-beds and sun-heat. To obtain good late Melons the plants must be set out in low, well-heated houses, the same as are generally used for Cucumbers at this season. There should be a steady bottom-heat of 80 degs. or so, and a top-heat of 70 degs. at night, with a suitable rise during the day to permit of a free ventilation to ensure hardy, robust foliage. The soil should be chiefly good sound loam containing plenty of body and fibre. It is not so much rampant growth which is required as that which is hard and firm, and this can only be obtained where the soil is of proper character.

Tomatoes under glass.—Do not overfeed with strong liquors, or the fruit may crack and be useless. Where top-dressings can be given containing a little manure matter there will be less need for chemical manures. Most plants under glass are doing well this season, and so far as I have seen there is very little disease, but the fruits ripen slowly in cool-houses, owing to the absence of sunshine and the low temperature at night. Tomatoes outside are healthy but very late, and the crop will be light. Better stop outside plants as soon as four bunches of fruit are set, as late-set fruits will not ripen, and late growths are useless.

Window gardening.—The brightest window plants just now are the Campanulas, which are so effective when suspended in baskets or on brackets, hanging down by the sides of the windows. Outside, the boxes of flowering plants are in many places very bright and effective, and a little weak liquid-manure will be useful now. Of course, all dead flowers and leaves should be regularly removed. At many of the local shows we have noticed very effective pots of annuals, which would be charming in the windows.

Outdoor garden.—The *Verbena* is evidently coming back again in a more robust form than when it disappeared, or nearly so, some twenty or thirty years ago. The *Verbena* is, as nearly as possible, a hardy plant, and its failure in the past may in a great measure be ascribed to over-propagation in strong heat. Let us hope *Verbenas* now will be treated more rationally, and that they may do useful work in the garden of the future. Cuttings of the young shoots will strike now in a close, cool, shady frame. Cuttings of other plants may be taken now. The *Geraniums* have not made much growth, and cuttings will be scarce. We shall take care of the best of the old plants, and strike the young shoots in early spring. Now is the time to sow hardy annuals to fill beds and borders in spring. Most of the Californian annuals will pass through our winters with safety. To obtain an early bloom the seeds must be sown this month, and planted out when the summer bedders are cleared off in October. This is the best season to move the *Madonna Lilies*, if they are to be moved, but it is generally a mistake to move them if they are doing well. Keep an eye upon the early budded standard Briars, and relieve the pressure of the ties in good time, and clear away all shoots from the stems.

Fruit garden.—Irish Peach Apples may be gathered and stored for a short time. This is one of the best of the early dessert Apples, though hardly so profitable as the *Devonshire Quince*, which is now putting on its brilliant colour. This is a popular variety in

shops and with the hawkers. Three of the best Apples to plant for profit where storage room can be had are *Bismarck*, *Lane's Prince Albert*, and *Newtown Wonder*. Where the fruits must be sold from the trees *Lord Grosvenor* and *Manks' Codlin* are sure bearers. In most places the *Jargonelle Pear* bears well as a standard, as do also *Williams' Bon Chrétien* and *Pitmaston Duchess*. One of the best dessert Pears is undoubtedly *Doyenné du Comice*. There is often more profit in such early kinds as *Hessle*, which can be marketed from the tree, than in the better dessert kinds which ripen later and require storing, and on good soils the *Hessle* grows to a large size and bears bushels of fruit each year. Where lots of kinds of Apples and Pears are grown a good fruit store is a necessity. One of the best fruit-keeping stores I have had anything to do with was a simple span-roofed structure built with hollow walls and a thatched roof, the windows being provided with shutters to use when necessary. There is still work to do among the forcing Strawberries. Runners are none too plentiful this season, and I prefer runners from young plants to old plants saved from last autumn's clearing up.

Vegetable garden.—Tomatoes in the open air will be late, especially when trained to stakes in the open. It will be better to stop the leaders when three or four trusses are shown and setting, and keep the side-shoots closely pinched in, but do not be in a hurry to remove foliage. This may be done in a tentative manner later when the fruit at the bottom begins to colour. The plants trained to walls or fences may be top-dressed or mulched with manure, but when grown in the open on a large scale in field culture, it will hardly be possible to mulch with manure, and the next best course is to use the hoe freely and keep the surface loose to encourage growth. There has been a good deal of rain lately, and winter greens are now growing rapidly, and some earth may be drawn up to the stems. Turnips just up should be freely thinned, and there is yet time to sow the *Red Globe* and *Chick Castle Blackstone*, which are the hardiest Turnips to stand the winter. Scarcely anybody sows enough *Winter Spinach*. It will follow the early Potatoes without much preparation beyond a sprinkling of soot and a deep hoeing. Most people sow *Tripoli Onions* for standing the winter, but other kinds, such as the *Globe* and *Spanish*, may be sown now and transplanted in spring. The best crops of Onions I have seen this season, except those autumn-sown, were sown in boxes in January and transplanted early in April. The Onion requires a longer season of growth than can be had from a late spring sowing outside. E. HOBOAY.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 23th.—Made up Mushroom-bed in house. Manure will be collected for other beds and the house pretty well filled during the autumn. The outdoor beds are giving a supply now, and this will be increased during the autumn. The beds which have been bearing some time receive liquid-manure, and a little salt in the water from time to time. We are still busy putting in cuttings of various kinds for next season's work. Sowed various annuals for spring.

August 25th.—There is a good deal of work among Tomatoes just now in cool-houses and outside, and we make a point of keeping the growth in check. The outside plants have been stopped, as the later blossoms are of no use and only exhaust the plants. Cucumbers in pits and frames have been lightly top-dressed. The necessary thinning and stopping are done weakly. A house has been prepared and will be planted with *Improved Telegraph* at once for autumn bearing.

August 26th.—Sowed several kinds of Cauliflowers on south border. Shall sow a few seeds later in a frame, as Cauliflowers are an important crop. Strawberries are now being potted for forcing. A good many plants are required, but those for early work will soon be in their fruiting pots. Later sorts, such as *British Queen* and *St. Charles Napier*, will

follow as soon as possible. A good deal of time is given to the renovation of flower-beds, such as pinching, pegging, tying, etc., and the constant removal of dead flowers.

August 27th.—The stove and several other houses have been repainted, both inside and out. This is the only way to keep out drip and preserve the wood. All potted fruit-trees, except a few Figs, are now outside ripening up wood. Peaches and Plums in pots which require a shift will have attention very shortly, and those trees which are now in large pots will be top-dressed, first removing as much of the old soil as possible. Celery for the most part is being blanched with paper collars, but will be earthed up to finish.

August 28th.—Arum Lilies in pots have been overhauled. Some have been broken up and repotted into smaller pots, as plants in 6-inch and even in 5-inch pots are useful for certain purposes, but the bulk of the plants will have 7-inch and 8-inch pots, and a few even larger. Ne Plus Ultra Pea is largely grown for late use, and where the pods were closely picked in the earlier rows a new set of blossom is showing. This often occurs with this Pea, and adds to its value as a late kind. A pit where a little warmth can be given when required has been planted with French Beans.

August 29th.—Herbs of various kinds have been cut for drying. Sowed Chervil. French Breakfast Radishes are still sown in a cool border, but we shall shortly go back to a sunny position again. Lettuces and Endives are being planted for winter on south borders. Looked over late Vinery to stop laterals which were inclined to ramble a bit. Less growth is made now, and a little more freedom is permitted in certain cases, but no foliage is allowed to remain in contact with the glass.

LAW AND CUSTOM.

Landlord's right to paint premises let to tenant.—Three years ago I took a house, just finished, of the ordinary bow-windowed, stucco-fronted type. My first care was to plant Ampelopsis against it, which has made splendid growth and reached to the second storey. Now, however, the landlord wants to cut it down in order to paint the house, which is semi-detached. The man is perfectly civil, but represents that the painting is necessary for the preservation of the stucco, and that it will be a serious injury to his property if it cracks or falls off. I have an idea that a close covering of creepers will be as good a preservative as the paint, and should be much obliged if you will tell me in GARDENING if I am right. Has the landlord the right to cut it down against my will? There is no covenant in the lease, except that he is bound to keep the outside of the premises in repair.—PORTALEX.

[I quite disagree with your contention that a close covering of creepers will be as good as painting; I should think it highly probable that in the course of time the creepers will cause actual injury. As the lease contains a covenant by the landlord to keep the outside of the premises in repair, a right of entry for the purpose of repairs is implied. I think the landlord has the right to cut down so much of the Ampelopsis as may be necessary to secure the proper painting of the stucco, etc.—K. C. T.]

Determination of tenancy.—I let a garden plot upon a verbal agreement for the term of five years. The term expires on Sept. 29th next, but my tenant says he shall not quit until a year's notice shall have been given and shall have expired. He has paid his rent half-yearly, and nine half-yearly payments have been entered in the rent book. What can I do?—A. E. J.

[A verbal letting for more than three years is void as a lease for the term stated, but after the tenant has entered and paid rent, he becomes a tenant from year to year during the continuance of the term. While the term continues, his tenancy can only be determined by a proper notice to quit, but his tenancy expires without notice when the term expires, just as though the letting had been valid. The five years for which you let the place will expire on September 29th, and so the tenancy expires on that date without notice from either party. If your tenant does not quit on September 29th you may take proceedings to recover possession, and your best procedure will be before the justices. But I must tell you that you will have to prove that you let the place for the term of five years, and you must consider for yourself how you can give proof if your tenant denies your statement and swears that the place was taken on a yearly tenancy. His word will be as good as yours, and he will prevail.

ment will appear the more probable on the face of it. If the rent-book shows that the place was let for five years, you should have no difficulty. In any case, you should get a solicitor to act for you in the matter.—K. C. T.]

Assessment to poor rate.—I am the owner of six cottages let at 6s. per week, and assessed at £9 12s. (net). This being a new neighbourhood there have been a number of cottages built since mine, some of them worth £40 more than mine, some let at 8s. per week and assessed the same as mine, others let at 6s. per week and assessed at only £5 (net). I have appealed to the Assessment Committee to get mine lowered. They tell me their rules are, for 6s. per week rent £9 12s. Am I bound to pay on that amount, whilst others only pay on £5? If not, what is my best course to take in the matter?—A. B.

[Property is required by law to be assessed at the sum at which it would let to a tenant who paid the rates, and although you probably pay the rates, it seems that you cannot complain that you are over-assessed. On the other hand, it is clear that the other property to which you refer is valued too low, and when you were before the committee you ought to have pointed out the instances in question, and you should have contended that the assessment of these properties was incorrect and unfair. Your proper course is to again give notice of objection to the committee and to the overseers and to the persons rated for the property to which you refer, and to appear before the committee in support of your objection. The result will be that the committee will not reduce your assessment, but that they will increase the assessment on those other properties which are now under-valued.—K. C. T.]

BIRDS.

Treatment of Green Parrakeet

(A. L. Richmond).—Feed your bird on Maize, boiled till soft, then strained and wiped dry, adding to this staple diet a little Hemp-seed, Millet, or Canary-seed. The Maize should be prepared daily, as it is injurious if allowed to become sour. Fresh water for drinking should be given daily, and a supply of coarse grit-sand provided to assist the bird in the digestion of its food. The grit may be given in a tin, and the floor of the cage strewn with fine sand, and scraped and cleaned daily. A little salt mixed with the grit, or a piece of cuttle-fish bone for the bird to nibble at, will help to keep it in health. Meat should never be given, and sopped bread very seldom—a crust of bread may, however, be allowed now and then, or a piece of hard biscuit. All the Parrot-tribe like to have something on which to exercise their powerful beaks, and a small log of non-splintering wood affords them much healthful amusement.—S. S. G.

Treatment of birds during their moult

(L. H. B.).—The moulting season being doubtless the most critical period of a bird's life, it is the time to afford it a little extra care and attention, and, although outdoor aviary birds do, as a rule, shed their feathers quickly and have no difficulty in renewing their plumage, it is well to afford them some help in supplying them with food of a more nourishing character than they usually receive. A supply of Linseed is beneficial, as is a small allowance of Hemp and Maw-seed, while some fanciers give a little hard-boiled egg, finely chopped and mixed with the same quantity of crushed plain biscuit. Drafts must be carefully guarded against, particularly at night, as a chill causes a check in the moult, and may lead to illness, or, at least, prolong the moulting and render a bird a ragged object for weeks. A tonic, provided by placing a rusty nail or a little piece of sulphate of iron in the drinking water, will prove very beneficial at this period. Yes, a little of the mixture known as "Purish's Chemical Food" is to be recommended, as it contains all the elements necessary for the elaboration of new feathers. Ten drops may be added to each ounce of the drinking water during the continuation of the moult. Give a liberal allowance of green food.—S. S. G.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE and GREENHOUSE PLANTS" or "THE ENGLISH FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, which will be marked with a star.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Finsbury Street, Finsbury, London, E.C. Letters on business should be sent to the Publisher. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind really assist in its determination. We have received from several correspondents single specimens of fruit for naming, these in many cases being scraps and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Camellia-leaves blotched (F. G.).—The man has probably been permitted to shine on them strongly when the house wanted more ventilation, and perhaps they may have been dry at his roots at some time when the leaves were young and tender. How have the Camellias been treated generally?

Keeping Cannas in winter (J. N. S.).—Send your Cannas underneath the stage in the greenhouse, taking care that too much water does not fall on them when you are watering the plants overhead. Break them up and repot about the end of February or early March, using light, rich soil. After this the water supply must be gradually increased until you want to plant out again in summer. Harden them off well before you plant out.

Pruning Banksian Rose (R. N. S.).—The Banksian Rose requires a warm wall and a dry border with two or three years' growth to bloom in perfection. Merely cut out a few of the old shoots that have bloomed and are growing, sappy wood now. Admit all the air possible so as to well ripen the wood. You may also remove any growth that has been injured by frost during the winter, but, beyond this, little pruning in spring is necessary.

Frosts and Chrysanthemums-falling (Constant Reader).—We should say that the frost has been the cause of your Frosts falling. The other day we had some Frosts the foliage of which was quite spoiled by the effects of frost in early July. Your Chrysanthemums have been attacked by earwigs, while there are also symptoms of mildew on the leaves. For the former, place some hollow stems of Broad Beans among the leaves. Use these the earwigs will go for abelter. They may be caught in the morning, when they should be shaken into a pail of hot water. For the mildew, dust with sulphur.

Planting Carnations (M. A. C.).—Your best plan will be to thoroughly dig up the soil where you intend making the bed, adding at the same time some good loam, well-decayed manure, and some soot and wood-ashes. Thoroughly incorporate all these ingredients. When planting, put a mixture of sand and fresh soil with soot, wood-ashes, or any ashes from burnt refuse, over the roots and round the stems. Before filling up, carefully water the plants. Plant early, and make the plants firm in the ground, so as to get a good root-hold able to resist the upheaving tendency of frost.

Tritomas (Cranehead).—You should mulch your Tritomas with leaves, bracken, or good coal-ashes, and if the plants are large, to keep them up to a pyramid of straw stakes to keep the snow out of the crowns. Do not in any case cut away the foliage, and, if insufficient to do up, first work 3 inches of ashes into the crowns while holding the leaves erect, and finally twist the foliage into a pleat, so to speak, over the top of the crowns. Let these so remain until March. They are best divided in the spring when this is necessary. Perhaps your soil is too heavy for the Scabious, as it always does best on a light warm soil, in which it is a true perennial, but perishes on cool soil.

Insects on a flower border (S. M.).—Insects infest your flower border largely, no doubt, because the soil is so sandy and porous. It may also be poor. If you could give the border occasional heavy soakings of liquid manure, and especially soot-water, great good would result. So also would a heavy coating of top-manure, laid on now and forked in in the autumn. To trap ants, get slates and coat them with treacle, on which is also sprinkled a very little powdered arsenic, as that will kill them wholesale. To trap woodlice, place here and there pieces of slate or tile hard pressed into the soil, then, on to those, other pieces, kept a quarter of an inch apart by tiny strips of wood. The insects will creep in between these during the day, and may be found and caught.

Diseased Ten-week Stocks (G. E. H.).—The few plants of Stocks sent are, for the time of the year, very small. They look as if sown very thickly, as the plants have been badly infested with aphid, which have sucked the sap from the leafage and caused the plants to wither. No doubt, your Astens have suffered from the same cause. You want for these plants well-manured soil. The seed should be sown thinly in shallow pans or boxes in April, and be raised in a frame or greenhouse quite near the glass to make the plants sturdy. After being well hardened by exposure in May, they should be dibbled out moderately thin at the end of that month, and, if it be dry, occasionally watered, especially overhead at night. If the plants get a check in the young stage they never later become strong. You seem to have a very poor strain.

Climbing Roses bare at base (M. O. E.).—It would not be advisable to prune the two plants now; so long as you cannot well prune them unless you sacrifice the blossom for one season. If there are two or three canes growing from the base, cut out one of them quite down

to the ground later on, say, about the end of October. If you were to repeat this each year you would soon have well furnished plants. Another plan is to take down the growth and re-bait them to the wall in a zigzag fashion, and at every bend new shoots will emerge, not immediately, but certainly later on. To avoid such a thing happening in the future, when climbing Roses are again planted, cut them back rather hard the first season, then you will obtain new shoots right from the base, and this can be maintained by cutting down one or more of the oldest growths each spring or autumn.

Pruning Rose Climbing Devoniensis (J. O. Chambers).—It is not pruning this plant requires. There is something wrong at the root, or it would be more vigorous than it is. This Rose, when it is doing well, will send out strong new wood thicker than the main stem of your plant. In November examine the roots by removing a portion of the soil. Should they be in a healthy condition, you have not laid hold of the soil, it will be the greatest economy to plant a good specimen on the Brier, or, better still, a half-standard. It is just possible your plant originally was pot grown. If so it would account for the want of vigour, as such plants rarely succeed as well as those grown in the open. When examining the roots have a little good compost at hand to replace such as you remove from the roots. This Rose should not be pruned until there is abundance of growth, and then only shorten the laterals, and remove soft, pithy wood.

Ants in a Rose-bed (Mary Dogne).—Ants are very difficult to destroy in a flower bed. There are only two ways of doing so—by taking up the plants whose roots the ants are infesting and destroying the nests, or by trapping them. The former is the far more efficacious way. You will probably find that the plant at whose roots the nest is attacked by aphides, and that the ants have made their nest to obtain the sweet material secreted by the aphidae. As soon as the plant is removed the nest can be destroyed by pouring boiling water into it, taking care to thoroughly cleanse the roots of the plant, so that none of the aphides remain on it when it is replanted. To trap the ants, set a good-sized pot, close at the bottom, half full with dry leaves, and then turn it bottom upwards on the ground close to the nest. Keep the soil moist, particularly that over the nest, wet, so that the ants may be driven to take shelter in the pot. Leave the pot unmoved for a fortnight, when you will probably find the entire nest in it. Empty it into a pail of boiling water. Watering the border with anything that will kill the ants would injure the Roses.

Hardy plants for bed (St. Leonard).—You do not give the size of the bed, which is always of some assistance in making a selection. As an edging, any of the Aubrietias, such as Phloxes as Nelsoni, Vivid, The Bride, atropurpurea, and amaran, or Achilles umbellata, silvery foliage and white flowers, may be used. The above are all dwarf, and 6 inches high. Phlox divaricata, Arnebia echioides, Dianthus superbiens, L. superba, L. Little Gem, Muscaris autumnalis, Leucojum vernum, Triteleia uniflora, Narcissus minor, N. Queen of Spain, N. Grande, Iris reticulata, Asclepias palmata, A. p. alba, Arabis alpina plena, Dianthus elegans, Achillea monensis, Triteleia pyrenaica, Statice latifolia, Saxifraga Wallacei, Meibomia cordata, atropurpurea, Polemonium richardsoni, Lychnis Haagei, L. Vaccaria fl. pl., Heuchera sanguinea, H. hrizoides, H. Bekedrechi, G. coccineum pl., Hybrid Columbine, Campanula medium Endressi, Coreopsis lanceolata, Campanula medium, Campanula alba, Anemone sylvestris, Anemone angustifolia, etc., include plants from 15 inches to 21 inches high. Those marked * are bulbous plants.

TREES AND SHRUBS.

Pruning Wistaria (J. Izard).—If your Wistaria is well furnished with flowering spurs, which form at the end of last season's growth, the young shoots may be cut back in November to within a couple of eyes of the flower buds. In this way they will develop much quicker when the sap begins to rise than if the long shoots were allowed to remain, and consequently flower earlier. To keep this sap back after year the young shoots should, soon after the summer, be pinched back to within a foot or so of the main stem. These shoots will again break into growth from the buds just behind where the shoot was stopped, and, after growing a few inches, they should be again pinched. This will tend towards the formation of flower buds at the base of the shoot just shortened, and, as the sap of the plant in the direction of growth has been checked, the buds will develop quicker than if this had not been done.

Striking cuttings of Himalayan Rhododendrons (S. Kiburn).—Though most of the Himalayan Rhododendrons can be struck from cuttings, they are difficult of increase in this way, and, to ensure success, special appliances are needed. The best cuttings are those of the shoots of medium vigour, not the very strong ones, which should be taken when they are in a half-ripened state, that is, as a rule, from midsummer to a month afterwards. The cuttings should be about 4 inches long, and if the shoots are only of that length, take care that the thickened portion at the base (that is, just where the springs from the previous year's growth) is allowed to remain, as roots are produced from that part more readily than from any other. When the cuttings are taken, remove one or two leaves from the bottom as may be necessary for insertion, and they are then complete. For their reception take some clean pots (those from 4 inches to 6 inches are the best), well drain them with broken rocks, and then fill with a mixture of equal parts of fine sand and silver sand pressed down very firmly. Into this insert the cuttings around the edge of the pot, taking care that the soil is closed tightly around each cutting. Then give a good watering through a fine rose in order to settle every thing in its place, and put the pots when filled in a close propagating case in an intermediate temperature. When then they will take three months to root, and in four months are sure to occur. If suitable cuttings can be obtained early in June, a few may be struck in a cold-frame if kept close, carefully shaded, and well attended to.

FRUIT

Keeping Apples (M. E. H.).—If the fruit is sound and carefully gathered, there is no better way of storing Apples than packing them carefully, with nothing between the layers, in boxes or barrels, leaving the lids open for several weeks, then shutting them tightly, and

placing in a dry, dark cellar or any room from which the frost is just kept out. Of course, you will understand that this only refers to late-keeping Apples, such as Wellington, Lane's Prince Albert, etc.

SHORT REPLIES.

See.—See article with illustration of Cactus Jenkinsoni in our issue of Aug. 9, p. 307.—**Han.**—Any hardy plant nurseryman can supply a collection of Phloxes.—**Mrs. Randall.**—Kindly say what you mean by St. Helen's Violets.—**Edward C. Deane.**—See article with illustrations on "Wall Gardens," in our issue of Dec. 23, 1901, which can be had of the publisher, price 14d.—**Clervous.**—The only thing you can do is to thoroughly trench the border, and, while doing this, to pick out every piece of root you can find.—**R. V. S.**—A Judas-tree would answer very well, but we should prefer the Mountain Ash.—**T. Fisher, Kellog.**—Allamanda Hendersoni, Ixora any, Clerodendron Thomsoni or C. splendens.—**E. A. R. W.**—1, Your Rose Bouquet d'Or will flower well next season on the growths you refer to. Keep these thin, and allow sun and air to reach them to ripen the wood. 3, See article and illustration of Iris Kempteri in our issue of Oct. 26, 1901, p. 455, which can be had of the publisher, post free, for 14d.—**J. Mayhead.**—Only a treak and of no value.—**M. L. Woods.**—Your Roses seem to have been suffering from the cold, unseasonable weather we have had, while we could also trace Orange-fungus, which you will find described in our issue of Aug. 2, p. 303. Kindly send specimens of the insect in a small box or bottle, as those you sent had been knocked about in the post.—**O. V. E.**—See reply to "J. Langley," re "Plum-tree gunning," in our issue of Aug. 2, p. 300.—**Wm. Thompson.**—It is quite impossible for us to say what is the cause of the Strawberries failing without further particulars as to age of plants, etc.—**J. Harding.**—Why not try Coleus Verschaaffelti, Iresine Herboldi, or I. Lindeni, cutting out the centre of the plant and encouraging them in this way to branch out and cover the ground? Your district is too cold for Alternanthera.—**A. R. St. C. Radcliffe.**—Yes, the Monkey Puzzle (Araucaria imbricata) frequently produces cones. There are instances of its fruiting in Scotland.—**M. W.**—The manure you speak of will answer perfectly well if it is fairly well decayed. If you use the cow-manure do not use stable-manure, more especially in your light, sandy loam.—**A Lover of Carnations.**—Try Paragon, a fine clear yellow, or Mrs. Prinsep, also a good yellow. Alma is a good pink.—**Luz.**—Apply to Messrs. Boulton and Paul, Norwich.—**Ajax.**—You will find an article dealing with "Madresfield Court Grape cracking," in our issue of Jan. 18 of this year. This can be had of the publisher, post free, for 14d.—**Julie E. Walsh.**—Wireworm is evidently the cause of the mischief, and was no doubt in the soil in which the Carnations were potted.

NAMES OF PLANTS AND FRUITS.

* Any communications respecting plants or fruits sent to name should always accompany the parcels, which should be addressed to the EDITOR OF GARDENING ILLUSTRATED, 17, FURNIVAL STREET, HOLBORN, LONDON, E.C. A number should also be firmly affixed to each specimen of flowers or fruit sent for naming. No more than four kinds of fruits or flowers for naming should be sent at one time.

Names of plants.—**Ashed.**—1, Potentilla hybrid var.; 2, Evidently a Mesembryanthemum. Kindly send leaves.—**M. W.**—We cannot undertake to name florists' flowers.—**Young Amateur.**—1, Hoya bella; 2, Lilium speciosum rubrum. There are many varieties of Lilium speciosum. Thanks for careful way of sending for name.—**M. E. G.**—Flower quite shrivelled up.—**F. Chute.**—We cannot name florists' flowers.—**Umbel.**—Cow Parsnip (Heraclium Sphondylium).—**T. H.**—1, Sidalcea campestre; 2, Melissa officinalis; 3, Linaria ep; 4, Sparganium Douglasi; 5, Eupatorium veratroides.—**A. R. L.**—Valeriana pyrenaica.—**N. E.**—White Melilot (Melilotus alba).—**Glenariga.**—Scabiosa ochroleuca.—**Templer.**—Spiraea Douglasi.—**A. M. R. Balerno.**—Deutzia crenata fl. pl.—**Jas. Isted.**—Ceanothus azurea.—**W. Hobby.**—Phacelia tanacetifolia; 2 and 3, Next week; 4, Loosestrife (Lysimachia vulgaris).—**C. S. T.**—Lysimachia clethroides.—**T. K. W.**—1, Grindelia glutinosa; 2, Eryngium Olivarianum.—**H. Sambourne.**—We cannot undertake to name florists' flowers.

Names of fruit.—**W. Williams.**—No numbers affixed to fruit. Please affix numbers and give us some idea as to habit of bush, this being of great assistance in naming Gooseberries.—**T. H.**—Pears: 1, Doyenné d'Ete; 2, Summer Bergamot.

URBANA-CHAMPAIGN

GARDEN & PLANT PHOTOGRAPHS, 1902.

THE EDITOR of GARDENING ILLUSTRATED announces Photographic Competition for the season of 1902.

Class 1.—SMALL GARDENS.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS for the best ten photographs or sketches of picturesque small gardens, including town and villa gardens, rectory, farmhouse, or cottage gardens.

Class 2.—FLOWERS AND SHRUBS OF THE OPEN AIR.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS to the sender of the best series of not less than twelve photographs of the above. These may include will plants or bushes, or any plant, flower, or shrub grown in the open air, including also half hardy plants put out for the summer, and either single specimens or groups, or the effects resulting therefrom, in beds or borders. Shoots also of rare or beautiful plants photographed in the house may be included in this class.

Class 3.—INDOOR FLOWERS AND PLANTS.—A prize of FIVE GUINEAS and a SECOND PRIZE OF THREE GUINEAS for the best series of indoor plants—greenhouse, stove plants, Orchids, or any other plant not of the open air—either single shoots, plants, or specimens, or the effects resulting from good grouping or other arrangements of such plants separately or in association with others. Ferns or groups of Ferns in houses may be included in this class.

Class 4.—BEST GARDEN FRUITS AND VEGETABLES.—A prize of FIVE GUINEAS and a SECOND PRIZE OF TWO GUINEAS for not less than twelve photographs of the best kinds of garden fruits and vegetables, Grapes, Peaches, Apples, Pears, Plums, Cherries, or any other fruit grown in Britain, to be shown singly or on the branches. Overcrowding, as in dishes at shows, should be avoided. The aim should be to show well the form of each kind, and as far as may be life-size. The object of this is to get good representations of the best garden fruits and vegetables under the old names, though we do not want to exclude real novelties when they are such.

Class 5.—GENERAL SUBJECTS.—A prize of FIVE GUINEAS will be awarded for the best twelve photographs of any garden subject not included in the previous classes, such as water gardens, waterside effects, rock gardens, picturesque effects in gardens, vases, cut flowers, table decorations, and pretty garden structures.

All competitors not winning a prize will for each photograph chosen receive the sum of half a guinea. In order to give ample time to prepare good photographs the competition will be kept open until November 29th, 1902.

WHAT TO AVOID.—Cut flowers or plants should not be arranged in vases with patterns on them. Backgrounds should be plain, so as not to come into competition with flowers. Figures of men or women, barrows, watering-pots, rakes, hoes, rollers, and other implements, iron railings, wire, or iron supports of any kind, labels, and all like objects should be omitted from these photographs. Dwarf flowers are ineffective when taken directly from above. The camera should be brought low down for such. All photographs should be mounted singly, and not several on a card. They should not be mounted on cards with black backs, and the photographs should not be less in size than 5 inches by 4 inches. The subjects should not be overcrowded. The following are the rules to be observed by all competitors:—

FIRST.—The photographs may be of objects in the possession of either the sender or others; but the source whence they are obtained must be stated, and none the copyright of which is open to question must be sent. There is no limit as to number, and no fee to pay. The Editor is to have the right of engraving and publishing any of the chosen photographs. The photographs may be printed on any good paper that shows the subjects clearly. Platinotypes and bromides should not be sent, but those so albumenized and printing out papers are preferred for engraving. All photographs should be properly toned.

SECOND.—The name and address of the sender, together with the name and description of the objects shown, should be plainly written in ink on the back of each photograph. Care should be taken to avoid the ink being seen on the face of the photograph. This is very important.

THIRD.—All communications relating to the competition must be addressed to the Editor, 17, Finsbury-street, Holborn, London, E.C., and the class for which the photographs are intended should be marked on the parcel, which must also be labelled "Photographic Competition." Unsuccessful competitors who wish their photographs returned must enclose sufficient postage stamps for this purpose.

Patent Greenhouse BOILERS.

The special merits of our Boilers are—
 1.—Long Burning.
 2.—Even Temperature.
 3.—No Trouble.
 4.—The Feeders being hinged can be pulled forward when desired, completely exposing fire-box.

In these particulars our Boilers are beyond competition. Guaranteed Minimum Burning 12 Hours Without Attention. It goes without saying that the large reserve of fuel in the Feeder insures burning for at least four times longer than is possible with ordinary boilers. Unsatisfactory Boilers can be replaced in a few hours' work without moving existing pipes.

EXTRAITS FROM LETTERS RECEIVED:—
 "My gardener says he never had such a stove before, so easy to work, and does its work so well." "Does its work splendidly, and is certainly the least trouble of any stove I ever had." "My man's message is "The last No. 21 had from you always goes 24 hours at a stretch." "I need not look at it but once a day, and have a good even heat the whole 24 hours."

PLANTS AND FLOWERS.

OUTDOOR PLANTS.

A YORKSHIRE WATER GARDEN.

ANYONE who has the advantage of water in or near the garden should try water and water-side gardening; the latter especially is full of interest. I began in a small way with a few early-grown plants at the edge of a gravel path bordering a small lake. The slow water-spearwort is a satisfactory thing, and soon spreads into a large clump. It might in time prove tiresome by overcrowding smaller and rarer aquatic plants. The American Pontederia nodata, though not showy, is well worth growing, with its blue spikes in August and September, and its handsome arrow-shaped leaves; it is also a free grower. Flowering rather later is the double-flowered Sagittaria, with a stock-like bloom; this is best planted right in the water. For spring nothing makes such a bright cheery spot of colour as the double dash Marigold (*Caltha palustris plona*) when sowed together on the water brink, the flowers lasting much longer than in the single variety. The dwarf Reed Mace (*Typha minima*), the variegated Sweet Flag (*Acorus*), *Arcus pseudo-cyperus*, a most graceful Grass, the pink-flowering Rush, the purple Loosestrife, with Water Forget-me-not creeping where it will, and rewarding you for its freedom by unlimited blooming, all grew and flourished on the water's edge of the path. *Himelus lutens* and *M. cupreus* grew riotously in the damp gravel, perfectly at home. Arum lilies were put in two summers ago, and even so far north as this have lived through two severe winters. One clump was planted in May close to the water. It flowered that autumn, and was a fine many-leaved plant when frost cut it down. It was then protected with damp leaves—the top layer of such only freezes—over them straw was built in a sheaf, and this remained till the following April. When once uncovered, it soon began to grow and flowered well, with stronger, larger blooms than any forced ones. Last spring some more were planted in a foot of water, being wedged down by Grass-sods and stones; these also were protected by straw, and now promise plenty of flower for this summer. Where the path widened on the water side, a long, narrow bed was hollowed out to 1½ foot depth, and filled in with peat, leaf-mould, and sandy loam. Here Japanese Irises were planted, *Primula japonica* grew and seeded itself, the summer Snowflake put up stems of 20 inches and flowered well, whilst Funkias and Saxifraga peltata, with their large leaves, kept it green all through the summer. In the shade of a Weeping Willow, *Osmunda regalis* (the Royal Fern) grew with its feet in the water, delighting in this cool, damp spot, and throwing out fronds 4 feet or 5 feet long, many of them hanging right into the water. The sweet-smelling Cape Pondweed (*Aponogeton distachyon*), which soon spreads by seeds, self-sown, and various Water Lilies helped to fill

up a small bay, whilst, for distant effect against a bank of Rhododendrons, were planted *Nymphaea Gladstoniana*, the beautiful white flowers of which stand well above the leaves, and *N. tuberosa* rosea, a strong-growing N. American variety with soft pink flowers.

My next attempt was the planting of a wild, Grassy margin, about a foot above the water, composed of sandy loam mixed with vegetable matter, always damp, but exposed to the north wind though open to the south. Here some moisture-loving trees were planted, such as *Cornus* (Dogwood), yellow and silver, red and yellow Maples, a couple of Quince-trees, *Viburnum Opulus* sterile (the common Snowball-tree), the Swamp Rose Carolina, and some of the shrubby Spiraeas, *Lindloynum* (better cut back each spring), *ariafolia*, and *japonica*. A Waterer, not forgetting one or two Silver Birches to give height and grace to the whole. To see perennial Phloxes in their beauty plant them in such a place, and it thinned out in June you will be well rewarded by the size and colour of their bloom. *Michnelmas* Daisies, Golden Rod, the red *Lycchnis chalcodonia*, all do well in this damp spot. Pampas Grass, with great clumps of Day Lilies, Iris Monspar and *Rodgersia podophylla* group well together. Think how well white Willow Herb, purple Loosestrife, with the long leaves of the common yellow Flag, the flowers of which would be over before the former bloomed, would look together. Nature's own arrangement! Ducks and swans have a great liking for water plants, especially when such are young and struggling for existence. With me they ate down some Cape Pondweed early in June; it was the autumn before it reappeared. If both ducks and flowers are wanted, wire netting is the only safeguard for your water garden.

MISS EVELYN WHITEHEAD.
Dreighton grove, York.

HERBACEOUS BORDER.

RELATING TO YOUR answer to my question on "Herbaceous Border," in your issue of July 25, p. 283. I want to have my long herbaceous border in flower for as long a time as possible, but especially from May and June to the end of the flowering year. I do not care so much for the early part—April. When I said progressive colours, I meant all the yellows, all the reds, all the blues should be together, and that there should be a progression of colours from, say, blues and mauves, through yellow and orange to red. By this means the blue part is always blue, and the red always red, and it may be easier to prevent the clashing of colours. I should certainly like to fill in with annuals and tender plants, like *Canna*, *Dahlia*, etc., but I want the foundation to be hardy herbaceous plants, and my lists of plants and advice you can give me I shall be most grateful for. I suppose *Sedums*, *Saxifraga*, etc., would be good for edging? The soil is sandy and very good for general plants, and I can have any quantity of manure. I should like to plant *Yuccas* at the end of the border. I suppose *Y. filamentosa* would be best? How close together should I put them, and would I fill in with other plants till they grow big? Which plants could I put in front of those which would be over in June, such as Irises, so that as much as possible the dying leaves may be hidden?—Stow Coach.

[We fear the massing of the colours as you suggest will render the whole arrangement patchy for a longer period than you would care for. Take, for example, the blue shades having a representative in Delphiniums. To these I would leave the Irises would be allied, and the red groups, each handsome alone, are

not suited to go together by their great disparity of growth. The pale yellow and golden shades also of the Iris would also find *Heleniums* and other things as companions, and so on. We give below, however, some of the families best suited to massing with their more decisive self colours, where such occur. Although we instance Delphiniums as an example of "blue," they yet include, perhaps, as many violet, bronzy-purple, metallic blue, and other shades as of real blue, such, for example, as *Belladonna*, *Cantab*, *Celestial*, *Lavender*, *Souvenir de Jubilee*, *conspicua*, and others. Those named are of shades near akin to the first, but these hardly agree with the other mixed tones named above. In such cases some modification is obviously needed in the selection of kinds. Most of the Delphiniums flower in June and July. *D. Belladonna* is a more perpetual bloomer, but not so vigorous, and only 2½ feet high. In the Iris family you will find pale blue and delicate mauve shades in the following kinds: *pallida*, *p. dalmatica*, *Imogene*, all rather tall growers. Of white Irises the best are *L'Innocence*, *Mrs. Chas. Darwin*, and *Mrs. Thorbeck*, the second being the most free-flowering of any we know. Yellow kinds are *Hortense*, *aurea*, *Darius*. In dark shades *Dr. Bornee* and *Arnolds* are very fine representatives; darker blue shades are seen in *Walmoriana*, *Ezra*, *Innocence*, *Sultan*, etc. These are May and June flowering. The herbaceous Phloxes are a fine group for effective massing, though requiring special treatment in respect to summer moisture. Some fine kinds are in white: *Jeanne d'Arc*, *Avalanche*, *Panama*, *Mrs. E. H. Jenkins*, *Independence*, *Sylphide*, etc. Red kinds are *Lothair*, *Coquelicot*, *A. F. Barron*, *L'Havant*, *Coccinea*, *Embrassement*, etc. The Pyrethrums, in single and double kinds, provide quite a host of reddish shades, more particularly in carmine, and rose-carmine, with velvet-crimson and other tones of high colour. Of the more showy of these we name *Captain Nares*, *James Kolway*, *J. N. Twerly*; for the double kinds, with *Coccinea*, *Sherlock*, *Duchess de Brabant*, and *Mrs. Bateman Brown* in the single reds. *Hanlet* and *Monarch* are the finest single pink sorts, and *Snow-drift* a good single white. Where your idea appears to be beaten offhand is in such things as *Gaillardias*, where, often enough, crimson and golden and orange combine in a single blossom. Still, these are so good as not to be ignored altogether. Of other things to be highly recommended, we may mention *Tritoma Uvaria*, red, *Echinops*, *Erigeron speciosus*, *Eryngium caelestinum*, *Scabiosa caucasica*, *Galega officinalis*, *Campanula grandis*, *Veronica longifolia sub-sessilis*, *Polemonium Richardsonii*, *Lupinus polyphyllus*, are all of blue or allied tone. In yellow there are *Crocus*, *Centaurea* several kinds, *Heleniums*, *Homeroicallis*, *Sunflowers*, *Rutbeckia Newmanii*, yellow and black centre, *Enothera macrocarpa*, *E. Youngi*, *Chrysocoma linostris*, *Doronicum*, *Arnica echioides*, and many more. White flowers are found in the perennial *Marguerites*, *Chrysanthemum maximum* and its varieties, *Galega officinalis alba*, the *Iberis*, *Galtonia candicans*, *Spiraea Aruncus*,

S. astilloides, *S. filipendula* fl.-pl., *Saxifraga* Wallacei, *Campanula carpatia* alba, *C. persicifolia* in its white forms, White Lupins, *Anemone sylvestris*, *A. japonica* alba, etc. *Lychnis chalcidonica*, *L. viscaria* fl.-pl., *L. fulgens*, *Lobelia fulgens*, etc., *Geum coccineum* pl., Oriental Poppies, *Lythrum*, *Chelone barbata*, *Hebechea sanguinea*, *Sedum spectabile*. *Saxifraga ligulata*, *Rudbeckia purpurea*, are all

Annual Candytuft (*Iberis umbellata*).

possessed of red, rose, or pink in some shades. Finally, the *Miclaemas* Daisies provide a great mass of material usually fully described in catalogues, together with height and other particulars that should be helpful in first setting out your borders on paper, which we strongly recommend you to do. In this way it will be possible to arrive at some idea of the flowering season of each block when the plants have become established.]

IBERIS (CANDYTUFT).

VALUABLE hardy perennials and annuals, the perennials somewhat shrubby and evergreen, and precious as rock-garden, border, and edging plants:—

I. CORREFOUJA (Correa-leaved Candytuft) is known by its large leaves and its compact heads

The Evergreen Candytuft (*I. sempervirens*) to show habit.

of white flowers. It also blooms later than other common white kinds, and both the flowers and corymb are larger and denser than in the other species. It is an invaluable hardy plant,

coming into beauty about the end of May when the other kinds are fading. It is excellent for the rock-garden, the mixed border, and the spring-garden, and is well suited for the margins of choice shrubberies, and may be used as an edging to beds. Said to be a hybrid. Increased by cuttings, not coming true from seed.

I. CORREFOUJA (Coris-leaved Candytuft).—A dwarf kind 3 inches or 4 inches high, and covered with small white blooms early in May. Few alpine plants are more worthy of general culture either in the rock-garden or the mixed border—for the front of which it is well suited. It is probably a small variety of *I. sempervirens*, but is distinct and true to its character. Easily propagated by seeds or cuttings, and thrives in any soil. Sicily.

I. GIBRALTARICA (Gibraltar Candytuft).—A beautiful plant, larger in all its parts than the other kinds, with flowers of delicate lilac in low dense heads in spring and early summer. It is a pretty species, but does not rival the best white border kinds. Its hardiness is doubtful, and it should, therefore, be planted on sunny spots in the rock-garden or on banks in light soil, and wintered in frames. Increased by cuttings, as it rarely produces seed in our climate. Spain.

I. JUCCUNDA (syn. *Ethionema juvenum*).—Distinct, growing about 2½ inches high, the leaves small, the flowers in small clusters, of a pleasing flesh colour and prettily veined with rose in early summer. It does not possess the vigour of the common evergreen *Iberis*, but it is valuable as a rock-plant; and is fitted for association with dwarf alpine flowers on warm and sunny parts of the rock-garden in well-drained sandy loam.

I. PETREA, a pretty alpine species, 3 inches high, with a flat cluster of pure white flowers, relieved in the centre by a tinge of red, thriving among the rock-plants. Many cultivators cannot succeed with it, but it thrives in a well-drained position with plenty of moisture.

I. SEMPERVIRENS.—A shrubby plant with large dense corymbs of white flowers, and not suited for border culture, but hardy enough to stand our winters when grown at the foot of a south wall or in a very sunny corner of the rock-garden. Under these favourable conditions it forms a pretty evergreen bush in bloom nearly all the year. Sicily and other Mediterranean islands.

I. SEMPERVIRENS (Evergreen Candytuft)—The common rock or perennial Candytuft, and as often seen as the yellow *Alyssum* and the white *Arabis*. Half-shrubby, dwarf, spreading, evergreen, and perfectly hardy, it escapes where many plants are destroyed by cold; and in April and May its neat tufts of dark-green foliage change into masses of snowy white.

worthy of cultivation: in fact, it and several other *Iberis* prove, when grown side by side, to be very slight varieties of *I. sempervirens*; it, however, seeds more abundantly, and is less spreading. *I. superba*, another variety, is of good bushy habit, and bears many large dense heads of pure white flowers.

I. TENOREANA (Tenore's Candytuft) is a dwarf species, with white flowers changing to

The glaucous Candytuft (*I. jucunda*).

purple. As the commonly-cultivated kinds are pure white, *I. Tenoreana* will be more valuable from its purplish tone as well as its neat habit. It has not, however, the perfect hardiness of the white kinds, being very apt to perish on heavy soils in winter; but on light, sandy soils and in well-drained positions on the rock-garden it is pretty. Where no rock-garden exists it should be placed on raised beds or banks, and is easily raised from seed; it should be treated as a biennial. S. Italy.

ANNUALS.

I. CORONARIA (The Rocket Candytuft) in good soil grows 12 inches to 16 inches high, with pure white flowers in long dense heads, and there is a dwarf variety of it (pumila), 4 inches to 6 inches high, forming spreading tufts 1 foot or more across. The Giant Snowflake is also an excellent variety.

I. UMBELLATA (Annual Candytuft) is varied in colour, and among the most beautiful of annual flowers. Seed may be sown at all seasons, but, as in the case of most other hardy annuals, the finest flowers are from autumn-sown plants which bloom from May to July. The plants like a rich soil and plenty of room

A mass of the Evergreen Candytuft by a carriage drive. From a photograph sent by Mr. G. Weir-Cosens, Aberystwyth.

Where a very dwarf evergreen edging is required for a shrubbery, or for beds of shrubs, it is one of the best plants known, as on any soil it quickly forms a spreading mass, as may be seen by our illustration. Like all its relatives it should be exposed to the full sun rather than shaded, and is readily increased by seeds or cuttings. Its common garden name is *I. sempervirens*. *I. Garrexianna* is not sufficiently distinct to be

to flower freely. There is a great number of varieties, differing both in growth and colour. What is known as the dwarf or nana strain is neat and dwarf in growth, an abundant bloomer and showy. *I. umbellata* nana roses and alba are two of the most distinct, being about 9 inches high; the dark crimson, carmine, lilac, and purple sorts, about 1 foot high, are also fine.

FLOWERS IN SCOTLAND.

The flower season, as far as the outside is concerned, is almost a failure here. The cold east winds which we are experiencing just now (August 11th) are making sad inroads on everything of a tender nature. Begonias, which have been planted in somewhat exposed

manure in autumn and spring, and division of the clumps every two years—this division being carefully carried out in November—there are now over two hundred healthy bulbs in the garden, and in the possession of other friends and neighbours. Some spikes this year (really the principal spike in each clump) were 5 feet 8 inches high, bearing from twelve to

clear water needful, cow-manure or sheep-droppings will all be found useful, and, if applied in time, will be the means often of plants blooming for weeks longer. When stimulants are not given during the season, and flowers are left on and not gathered when they ought to be, then danger arises of failures occurring. Sweet Pea growers can avoid this now, and have a continuous supply of beautiful flowers for many weeks yet by a little daily attention.—W. F. D.

Colonies of the Evergreen Candytuft in the rock garden. From a photograph sent by Mrs. R. Phillips, Wulverie, Olton, Warwick.

Lobelia fulgens.—Very familiar are the intense scarlet blossoms of *Lobelia fulgens*, but in some gardens it frequently dies off during winter from want of protection. At the present time its flower spikes are conspicuous in the herbaceous borders, growing to a height of 3 feet or more when planted in a rich deep soil. This *Lobelia* should be lifted from the open towards the middle of October and placed in a cold-frame; if the frame itself is under a wall, then it is best to plant the *Lobelias* as near to the wall as possible, as there it is always the driest in winter, and damp is one of its worst enemies. If one wishes to increase the stock, the spring is the time when new growth commences.—W. F. D.

Carnations from cuttings.—Everyone is more or less conversant with the art of layering Carnations, and much labour is expended on this operation, but in these days of keen competition it behoves all who have anything to do with growing for profit to curtail the labour as far as possible. I find that cuttings of Carnations strike so freely that it is far less trouble to increase one's stock in this way than by layering. Prepare a bed of fine gritty soil under the partial shade of a fruit-tree, and take the cuttings in the usual way. Trim off the lower leaves, and then split the stem of the cutting with a sharp knife, and insert a small stone to keep the cut part open. Insert the cutting and water freely, and at least 90 per cent. will make good plants.—J. Groom, Gosport.

Propagating Pelargoniums.—These very popular flowers may be propagated with the greatest certainty while the days are long and there is plenty of sun-heat, but if left until the cool, damp autumn weather sets in a large percentage of the cuttings decays. Those who need a good supply of healthy young plants should make a start at once by taking off a cutting wherever it can be spared from pot-plants or flower-beds, and, having some nice, fine, sandy soil ready, insert them singly into quite small pots, and set them in a cold frame, when the lights can be pushed over them during heavy rains, leaving open at

positions, are denuded of almost all foliage, and have as yet shown no signs of bloom. On the other hand, those plants in sheltered places have bloomed admirably, considering the backward season, but the foliage is poor and stunted, and lacks the robustness and freshness of former years. Asters have almost utterly failed. Ten-week Stocks have done well, and are extremely showy, the seed, which was of a good strain, coming about 99 per cent. double, the spikes resembling a well-grown Hyacinth. The east winds seem to have no effect on these plants. Gladioli have thrown good foliage, but flower-spikes are slow in making their appearance. Geraniums of the *Vesuvius*, *Jacoby*, and *Flower of Spring* type have made a very poor show in comparison with former years. French and African Marigolds seem to be up to their usual standard when grown in sheltered positions. *Lobelias* are one mass of bloom, the plants having been raised this season from seed. Dahlias (show and fancy) are somewhat stunted in growth, but the blooms are as fine as ever. The single *Cactus* forms have done very well, and the blooms have been in much demand for cutting. Roses have been very fine, although nearly a month later in blooming. *Baroness Rothschild*, *Magna Charta*, *Captain Hayward*, *Duke of Edinburgh*, *General Jacqueminot*, *Paul Neron*, and *John Hopper* as standards have been very fine. Hardy annuals are much the same as usual, although somewhat later. Tufted Pansies have been grand, and are now one mass of bloom. D. G. McIVER.

Bridge of Weir, N.B.

NOTES AND REPLIES.

Lilium testaceum.—This is a lovely kind, although seldom met with. It has done well with me for the last twelve years in a mixed border. One bulb was planted at first, when it only gave one spike; now, the end of July, I have eight, the tallest nearly 7 feet high, with large umbels of bloom. This has never been removed or taken up during the twelve years.—J. Crook.

A border of Madonna Lilies.—In 1893 a bulb of *Lilium candidum* was given me by a friend. Planted in a garden soil that was somewhat rich and heavy (clayey loam), the size of the five offsets produced by the first rather small bulb showed, in 1897, a remarkable improvement. By liberal treatment as to

seventeen fine white blooms. The effect of this long border seen against a background of *Crimson Rambler Rose*, and with scarlet *Carnations* and *Iceland Poppies* in the front of each clump, was unusually fine. The heavy rains of spring and summer greatly helped to increase the size and healthiness of the plants.—EDITH E. REDNALL, *Sitchester Villa, Wokingham.*

Sweet Peas—keeping up a supply of flowers.—After Sweet Peas have been in bloom for a time they are liable to cease flowering if one or two conditions are not observed, the first being that no seed-pods must be permitted to mature and that all old flowers must be cut off, and, secondly, that the plants still have some kind of stimulant, so that new life, as it were, may be infused into

The Gibraltar Candytuft (*L. gibraltaria*)

them. Everyone who has grown Sweet Peas in any quantity is aware that once seed-pods are allowed to form and flowers are not gathered, blooms begin to fail. Mulching about the roots with half-rotted manure, and applying a little guano, after first giving the

all other times. Give one good watering to settle the soil well around the stems, and then only enough to keep them from withering, and they will soon push out roots, and make good plants by the autumn. By following up this plan for several weeks plenty of stock will be

obtained without disfiguring the beds. Pot-plants headed down now will have plenty of time to make a good head of young shoots for winter flowering.—J. G., *Gosport*.

Lychnis Haageana.—On page 324 a correspondent, "B.," says of the above, "it is not perennial, and must be raised every year." My experience of the group which is now known by the name cited is that the plants do not reach their best condition until the third flowering year. It is quite possible, however, that "B." may have lost his plants from an attack of slugs, for these greedily devour the small tuber like roots to which are attached the crown-buds or eyes, and frequently in heavy soils the entire plant is demolished. The plant usually is not happy unless grown on sandy soil, or soils that are well drained and light. Even on these soils I find the plants are the most vigorous in quite the warmest places, such, for example, as near a warm wall or the like. Some years ago I planted several pots of plants rather close to a bay window in a small front garden, and despite the nearly south aspect, the much increased heat by the proximity to the house wall, and a soil both poor and light, the plants grew into bushes and attained in the fourth year nearly 3 feet high, giving a blaze of brilliant flowers far larger than I had ever seen hitherto. Plants of the same age in the open beds in similar soil were so vastly inferior in every way that I have since regarded the plant as one of a number of warmth-loving subjects, and, in truth, there was in the instance cited nothing but the excessive poorness of soil and the much increased warmth of position to account for all the superiority of growth and blossom. The group may not be so hardy as some suppose, and the crowns are never safe from frost unless 3 inches at least below the surface. Certainly, no plants of even biennial growth and flowering could at all compare with the dozen or more stems and the great crown of rich flowers borne on the plants I have referred to.—E. J.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS—SEASONABLE HINTS.

With the advent of September, we may fairly consider we have entered the period of flowering of the early-blossoming Chrysanthemums, and for this reason it is important not to neglect the important item of feeding. Any ordinary garden soil which has had a dressing of good manure will grow the plants well, but if in addition to this are given frequent supplies of liquid-manure, the return in the shape of excellent blossoms, and a good crop withal, may confidently be anticipated. The present season has, so far, been an exceptionally dull and moist one, and the wood is not so ripe and hard as it should be. In consequence of this want of ripening, the plants will not do so well as usual, unless special means be taken to help them. In wet weather the plants are much benefited by a dusting around the base of some approved fertiliser. At this stage the roots on the surface readily assimilate the constituents of plant-food available in each manure. It is a good plan to keep the surface-soil between the plants well stirred. If this be done in dry weather with copious supplies of manure-water, and the surface sprinkled in wet weather with artificial manure, the effect on the plants and the blossoms also will be most marked. Without the use of manures many of the promising buds now freely developing will produce blossoms of poor or semi-double character. Keep the shoots tied out, or lopped in such a way that air may circulate freely between the growths and thus help the wood to ripen. Strong winds may safely be predicted at this season, and see that each plant is securely staked. It is just possible that the first stakes to be inserted may not be long enough or strong enough to support the heavy branching growths of some of the more robust plants. If left too long, the grower may have to mourn the loss of promising plants.

Disbudding.—Already persons are asking questions about disbudding the early sorts. Plants grown to make a display in the beds and borders should not be disbudded except

perhaps, in a comparatively few instances, representatives of which I will name later. If, however, some of the early sorts are growing in pots, and are intended for the embellishment of the conservatory, these may be partially disbudded, in which case their usefulness for decoration is enhanced. But in the garden the plants never look better than when they are grown quite naturally and without disbudding. There are several varieties which develop their blooms on fairly long stems without any disbudding whatever, and these are the kinds which should be looked after. Any individual bloom may be detached from the spray without spoiling the others, and this is a point of much importance, and should not be overlooked. *Mina Marie Musse* and the sports from this grand variety are typical of what hardy outdoor Chrysanthemums should be, and there is now a sufficient number in this one family to satisfy the requirements of most growers. Contrasted with the sorts just mentioned we have other excellent kinds, each of which produces a profuse display of blossoms, but, unfortunately, in dense clusters at the apex of each shoot. The flower-stems are so short that the flowers are all packed closely together, and individual blooms cannot be gathered unless the plant has previously been disbudded. Types of this class of plant are *Mlle. Guindreau* and its sport *Eva Williams*. They are both very pretty, but cannot be regarded with anything like the favour of those sorts first described. E. G.

ROOM AND WINDOW.

LILIUM LONGIFLORUM IN A WINDOW-BOX.

PERHAPS the following may interest your readers. Last year I tried growing *Lilium longiflorum* in a window-box, and was very successful, so this year I tried again, using a rather wider and deeper box, commencing in March by putting about 3 inches of Cocoa-nut refuse at the bottom and half plunging the bulbs in this. The box was then put in a room without a fire, only getting an occasional slight sprinkling of water. Early in May roots were formed, and the bulbs had sprouted about an inch. The box was then placed on the window-sill outside, filled up with ordinary potting soil, and a few plants of *Myosotis* planted on top. Afterwards it had no special care but watering, and after the buds had formed, about half-a-dozen doses of a tea spoonful of ammonia in a gallon of water. A slight attack of green-fly was at once got rid of by sponging with Tobacco-water. The result has been thirty-seven flowering stems with perfect foliage, and an average of three flowers each. One had five, and several four, and only one split bloom; all the flowers exceptionally fine, just over 5 inches from tip to end of flower. The only fault, if any, was that the stems were rather crowded, but the general result was very good. The bulbs were imported Japanese. Many of those used last year have bloomed in the small back-garden this summer, but, of course, not well.

MISS F. ECHEVARRI.

155, Silvermere-road, Catford, S.E.

NOTES AND REPLIES.

Effective arrangement of flowers in vases.—Recently a correspondent in *GARDENING ILLUSTRATED* made a most important statement when writing on cut flowers—namely, that many people destroy the effectiveness of their arrangement by mixing a lot of colours together. Observant people must have noticed this with a large number of cut flowers. The same holds good with plants, shrubs, etc., grown for ornament in the garden, and nothing seems to be more difficult than to convince them that the best results are obtained by placing one or two well chosen colours together or planting large groups of one colour. In my own cottage, in a vase hanging against a wall, is *Crimson Rambler* Rose, cut in large long clusters, with numberless blooms loosely grown. Two of these are used with a long spray of *Ceanothus* *Gloire de Versailles* at the back, and a few sprays of *Rhus Cotinus* covering the sides of the vase, and three or four leaves of *Roccosia cordata*

interspersed. This, backed by a light paper on the wall, gives a glorious picture. Yellow *Marguerites* and *Mignonette*, with *Asparagus greenery*, in low glasses are good. Red Sweet Peas and *Mignonette*, with *Asparagus* as greenery, or their own foliage, are good also.—J. CROOK.

Keeping cut-flowers.—I have read an article on keeping cut blossoms in your paper (August 9th). Few people think of giving the water a good chance of getting to the bloom up the stalk. There is hardly a flower that does not last a day or two longer if its stem is split up an inch or two just as it is put in the water. Roses like a long sloping cut downwards. Hard-wooded shrubs like *Lalac*, *Rhododendrons*, *Syringa*, should have all the bark peeled off as much stalk as goes into the water, and will last a good week instead of drooping in a few hours.—SWEET LAVENDER.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

The leaf-cutter bee.—Kindly inform me what is the proper name of the enclosed bees, which are most destructive? They bored holes in a 4-inch finial on the roof, and completely destroyed it. They carry in green leaves to the holes. The one enclosed, and also another one, were both caught this morning with a piece of Rose-leaf in their mouths. How can I get rid of them, as if they go on I do not know where the damage will end? The finial has been renewed. The bees in the old one are all destroyed, and these are the first I have seen since, but quite in a different place.—ANNIE PAER.

[The bee that you sent is a specimen of one of the leaf-cutter bees, belonging to the genus *Megachile*, but the specimen was so knocked about by being placed loose in a box that it is impossible to say to what species it belongs. These bees make their nests in holes in wood, in walls, or dry banks. I should doubt if they would select sound wood for their purpose. Probably your finial was somewhat decayed. I have had nests sent me which were made in a coil of paper and in a hollow stick, but have never heard of their being the cause of any damage before, though complaints are often made of the way they spoil the leaves of Roses. If you cannot trace them to their nests, the only way is to catch them on the Rose-bushes as you have done. The mother bee, having found or made a suitable hole, lines it with pieces of Rose-leaves or the petals of some flower, and then fills it with a mixture of honey and pollen as food for the grub, which will be hatched from the egg which she lays in the cell. She then proceeds to form another cell in the same hole, the lower end of which fits partly into the mouth of the first, just as one thimble might fit into another. In this way the hole is filled. It is very pretty, as I dare say you may have noticed, to see the bee cut a piece out of a leaf and fly off with it. I do not think you need fear that the bees will do you any real injury.—G. S. S.]

Pear Saw-fly.—We have received a small green box with two Pear-tree leaves on which are some insects, but no letter or communication of any kind was enclosed. The foliage of the Pear-tree is attacked by the grubs of the "Pear Saw-fly" (*Eriocampa adumbrata*). The grubs are commonly known as "sling worms," though they are neither slugs nor worms, but they very much resemble small slugs. If the tree is bearing a crop of fruit it is difficult to know what to recommend as a remedy. Syringing the tree with paraffin emulsion, properly diluted, or Tobacco-water and soft-soaps, and dusting the leaves with finely powdered lime or gas-lime, are useful. Even the road-dust has been used with advantage, or you might spray the tree with "Paris-green." This last, however, is a very poisonous substance and must not be allowed to touch the fruit. When full grown, the grubs bury themselves in the ground just under the trees, and between 3 inches and 4 inches below the surface. They then each spin a thin papery cocoon round themselves, within which they become chrysalides. During winter, if the surface soil which contains the chrysalides be removed and burnt or buried not less than 1 foot below the surface, or placed so that the poultry can pick it over, the trees should be free from this pest next year. The earth taken away should be replaced with some good soil that is certain to be free from this pest.

INDOOR PLANTS.

ZEPHYRANTHES.

A SMALL group of bulbous plants belonging to the great order Amaryllidaceae, yet small as it is in its entirety, the number of good, hardy kinds is still greatly reduced by comparison. All the species are beautiful and easily cultivated. Some, indeed, as *Z. Atamasco* and *Z. candida*, grow quite freely, and soon become established masses that might be increased to any extent by the numerous offsets produced. In form the flowers of the smaller kinds are not unlike those of the Crocus, and vary from such as those to others of the size of *Colchicum speciosum*, of which *Z. rosea* may be taken as a near approach thereto in point of size and not a little in colour. All the kinds may be successfully grown in sandy loam, and when grown in pots form quite an attraction when in flower in the early part of the year. Those best suited for pot culture and the greenhouse, perhaps, are such as *Z. carinata*, *Z. rosea*, *Z. tubispatha*, etc. Little warmth is required, though it is quite necessary at all times that the bulbs are not subjected to any temperature approaching the freezing point. That of 40 degs. may be regarded as a safe minimum for the less hardy kinds. The perfectly hardy kinds are

the less so should be of service to those amateurs who are inclined to the other extreme—viz., that of too frequently interfering with established pots of rare bulbous plants. In the case of any whose growing season is not of long duration, very little goodness would be extracted from the soil, hence there should be little need for interference. The following are the more valuable kinds:

Z. ATAMASCO, with large pure white flowers nearly 3 inches in length, and with the stem rising to 6 inches or 8 inches high.

Z. CANDIDA, sometimes called "The Flower of the West Wind," is also a pure white flower, more resembling a Crocus-blossom, and quite hardy. This species should receive plenty of moisture in the growing season and as the heat of summer approaches. It is a pretty plant for forming edgings, masses, and the like.

Z. CARINATA, a handsome flowering plant with blossoms of a pleasing delicate rose-shade. A charming pot-plant for cold-house, or may be grown in a sunny frame in the open. Native of South America.

Z. ROSEA, also a handsome kind with large cupped blossoms of deep rose, very striking when well grown.

Z. TREATIE, a beautiful white kind somewhat allied to the first, the blossoms having a deli-

cate, give a little more water and syringe occasionally, which treatment will result in young shoots being pushed out freely all over the plants. When these shoots are about half-an-inch long the plants may be repotted in a mixture of two parts loam to one part each of leaf-mould and well-decayed manure, with a little sand. In potting, the greater part of the old soil may be removed. When this is done, if watering and occasional syringing are carried out properly, and the plants kept in a light, airy greenhouse, they will in due time grow and flower well. As the pots get full of roots, and the plants show signs of becoming exhausted, an occasional dose of artificial manure will then be of service.]

Treatment of Hydrangeas.—I took some cuttings of Hydrangeas in the spring. They are now growing nicely in 4-inch pots. I want them to bloom in the spring, with one large head to each plant. Will you kindly tell me how to treat them now and in the winter?—W. B.

[We presume your Hydrangeas have well filled their 4-inch pots with roots, in which case you may at once put them into pots 5 inches or 5½ inches in diameter. In potting, do not disturb the roots more than is absolutely necessary, and use good soil, say two parts of loam to one part each of leaf-mould and well-decayed manure, and a little sand. Then place them out-of-doors in a spot fully exposed to sun and air, in order that the wood may be thoroughly ripened, and keep well supplied with water. As autumn advances, and the leaves begin to turn yellow, place them in a frame where they are just free from frosts during the winter. With the return of spring they may be taken into the greenhouse, where their heads of flower will develop. As soon as they start in the spring a little weak manure-water occasionally is of great service. As the blossoms develop a good light position should be assigned them, as their colour is improved thereby, while the plants are apt to run up weak if kept close and shaded.]

Bouvardias.—Bouvardias are useful during the winter in a warm-house, but neglect on the part of the grower at this time of the year will often prevent their blooming with that freedom they would otherwise do. They are not difficult to cultivate, and as they are easy of propagation one may soon increase the stock. All plants should now be standing in cold-frames, with room between each one, in order that wood may properly mature. Those in 5-inch pots when full of roots soon become dried up, and care must be taken that they are not lacking moisture. At present liquid-manure may be given them, but in a weak state, and a bag of soot placed in the tub from whence the water is procured will aid in imparting a good colour to the foliage. It is not safe to leave them out-of-doors much beyond the middle of September, and preparations for housing them should accordingly be made about that time.—LEAVIST.

Deutzias for forcing.—These hardy shrubs are amongst the most popular of those that are brought indoors in the autumn for forcing into bloom in the early spring. As a market plant the white blossoms of *Deutzia gracilis* are much in evidence in March and April, and grown in moderately-sized pots (5 inches or 6 inches) are useful for table-decoration. After blooming *Deutzias* should be relieved of old wood, and as much new growth as possible encouraged. The permitting of old wood to remain is one of the reasons why small, puny blossoms follow. Loam, with which leaf-mould has been mixed, makes a suitable compost for them. Cuttings of ripened wood strike freely in sandy soil.—TOWNSMAN.

Photographs of Gardens, Plants, or Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mrs. Baydon, Dawlish, Devon, for Iris (Gates); 2, A. P. Davison, Broughton Grange, Banbury, for

The white Zephyr-flower (*Zephyranthes candida*) in a pot.

just as hardy as the Crocus, though scarcely so free flowering in the general way. The majority of kinds best known to cultivators increase freely by offsets, and these, if planted six or eight around the inside of pots of about 5 inches diameter in good, rich soil, will quickly make up flowering bulbs. As showing how easily grown are some kinds such as *Z. rosea*, I may instance a gardener who has many pots of bulbs that have probably been in his keeping a score of years, and certainly not potted half-a-dozen times in that period, who produces quite a display each year with the richly coloured flowers. Some of the pots are quite full of bulbs, and without knowledge of the subject in his charge, beyond that of keeping them dry when they go to rest, little or no attention is paid to them. Such crude and indifferent treatment may in some degree suggest that others are over-cultivated or coddled, perhaps, far more than is necessary. In the instance referred to, however, I believe much of the success that is achieved is due to the long protracted term of dryness to which the bulbs are compulsorily subjected year by year. Certainly no season passes without many flowers, and large ones too, and as the flowering approaches I generally receive an intimation to that effect. How far this may be in agreement with the prescribed methods of culture is an open question, and it is as much an open question whether a larger display of flowers would follow if the plants were grown in a more orthodox way. For my part I think

into Lily-like fragrance. The plant attains nearly 1 foot high, and at present is somewhat scarce. E. J.

NOTES AND REPLIES.

Fuchsias failing.—I have a collection of Fuchsias that has much disappointed me, as there has been scarcely any bloom this season. They are of several varieties. Some are old plants of last year, and others were struck in the spring. Some are in small pots, others in large ones; some in a conservatory, others out-of-doors. But while they thus differ in some respects, they are all alike, or nearly so, in having little bloom, or none at all. I gave some of them a dressing of artificial manure a few weeks ago, which set them growing vigorously, but it is all foliage and no flower. I suppose it is too late to expect any bloom worth speaking of this season? What treatment would you advise as most likely to get better results next year? Has the exceptionally cool and unseasonable weather we have had conducted to the failure of bloom?—Q. Q. Q.

[Fuchsias are in many places flowering badly this season owing to the wet and cold weather, of which we have experienced so much this year. It is, however, strange that under whatever conditions your plants are placed they are all nearly flowerless, as in the conservatory they should have bloomed long before this—that is, if they were not kept too close and shaded. It is certainly not yet too late for a fair amount of bloom on some of them, as very fine flowers are often borne towards quite the end of the summer. We should advise you to winter your plants in a greenhouse, keeping them almost dry at that season. Then, about the end of February or early in March, go over the plants and trim them into shape. Under

ROSES

OWN-ROOT ROSES FROM SINGLE EYES.

THE following description of a beautiful Rose in my garden and how it came into my possession will interest some of your readers, especially those who, like myself, are, either from choice or necessity, their own gardeners. I do not know the name of the Rose, but it is one of the Tea section, and delightfully perfumed. The flower is large and full and of the finest form. The colour on the outer edges of the petals is a lovely soft, satiny pink, deepening towards the centre into the richest apricot and gold. The leaves are of the darkest glossy green, and the wood or stems a rich copper brown, and where not exposed to the sun the young wood is coral-red. I first saw the Rose in a friend's garden in July, 1897, and was kindly given some pieces of the wood, which it was thought were likely at that particular season to make good slips or cuttings. Having seen an interesting article in *GARDENING ILLUSTRATED*, "How to Grow Roses from the Bud," I thought my best chance of success was to make the attempt. Unfortunately, I could not find the number of the paper I wished to consult, but as I remembered the directions, at least so far as to how to cut out and prepare the buds for setting, I decided to make the attempt, and trust to my own experience for the after treatment, which was as follows: I prepared three flower-pots, two 5-inch and one 4-inch, which were filled to the brims with carefully prepared compost, the largest portion of which was silver-sand, three closely fitting bell-shaped propagating glasses, and a few medium-sized hairpins.

With these preparations I made my first attempt, cutting out only one bud at a time, and with as little delay as possible, after removing the pith to avoid the drying up of the sap, laid the bud on the surface of the compost, and secured it in its place with hairpins on both sides of the bud. Then, after a light watering with tepid water through a fine syringe, I placed on the glasses, and for some weeks after continued to water the cuttings only outside the glasses, which I found sufficient to keep the surface moist till the rooting had commenced. The three pots were then put into the cool greenhouse, and placed on the shady end of a front shelf. In a few weeks five of the buds filled the pots with roots, and formed beautiful little green bushes. The sixth bud was not so vigorous, and failed to survive the winter. Four of the five plants are to be seen at the present moment in full bloom, delighting everyone who sees them with the beauty of their flowers and the sweetness of their perfume. One of the four plants, I should have said, was lost or perished while changing to my present residence. The only part of the experiment I claim as my own is the introduction of the hairpins, which will be found not only a great help, but an absolute necessity to keep the fragile buds in close connection with the compost. ROSEBUD.

[From your description we believe the Rose to be Mme. Cadeau Ramey, but could you not send us a bloom with wood and leaf? It is quite possible, as you describe, to obtain rooted cuttings from single eyes, and we frequently adopt this plan when a variety is scarce. When it is remembered what a fine plant will spring from a tiny bud inserted into a foster stock, it is not at all remarkable to obtain good plants from a single eye or bud by the process you mention, but you would have obtained equally satisfactory results if you had inserted the single eye into the compost in the same manner as one does when striking Vines. At this time of year it is quite practicable to obtain a leaf with each eye or bud. Let this leaf remain, and instead of removing pith from the wood, cut the growth just below the eye in a wedge shape, and stick this into the sand or compost its entire length, leaving just the leaf protruding. You will obtain a far more sturdy plant in this way than from the process you name. Rose shoots that have just flowered make splendid cuttings and root most freely during the early part of this month. They only require frequent sprinkling for the first fortnight, and to be kept in a close frame. They root as freely in pure sand as they do in a sandy compost; in fact, we prefer sand, but

the cuttings must not remain in it too long when rooted, or they become weak. Pot them off when roots are $\frac{1}{2}$ inch long. Another good plan is to fill a number of thumb pots with sand, stand them as thickly together as they will go in a shallow frame, then work in sand into the interstices. Dibble a cutting into centre of each pot with its leaf attached, then arrange to have them sprinkled every hour from 9 a.m. until 4 p.m. for the first ten or fourteen days. Shade the glass with paint or whitewash, with which some oil or size has been mixed. When the cuttings are rooted, air can be gradually afforded until it is safe to remove the lights entirely. These little plants may then be potted on without any check, or planted out into beds so arranged that lights may be placed over them in severe weather.]

ROSES FOR SPAN ROOF HOUSE.

(REPLY TO "BEGINNER.")

WE presume your house is not shaded from the south by any building, as Roses cannot have too much sunlight at any time, and during the winter and spring it is most important to give them all that we obtain. Instead of making a pit, we should recommend a raised bed about 2 feet in height. The outer wall could be of bricks, and the centre filled with stones or ashes. The Roses could then be placed upon inverted pots, which would bring them nearer to the glass than if you plunged them in ashes. Four or five half-standards would be very suitable for the centre row, and around these we should advise strong growing Teas and Hybrid Teas trained in pillar form. Give the plants one central cane, and loop up the growths to this instead of spreading out in the usual manner of training pot-Roses. Any of the free-growing Teas and Hybrid Teas, such as Marie Van Houtte, Anna Ollivier, Mme. Hoste, Climbing Niphotos, Maman Cochet, Mme. Abel Chatenay, would do for the half-standards, and for pillars, Catherine Mermet, Souvenir d'un Ami, Perle des Jardins, and Roses of that type. These pillar Roses should be purchased in 8-inch pots, ready prepared for forcing, and if you explain to your nurseryman what you require you will obtain the right kind. The staging around the house could most certainly be used for other pot-Roses, and either grown as bushes or trained on to the roof. Varieties of Teas of vigorous growth, such as Sunset, Niphotos, Perle des Jardins, and Bridesmaid, would be the best for either purpose—far better than the ordinary climbers, as they impede the light too much from the other occupants of the structure. In all cases the best plants to procure are those known as extra sized, grown in 8-inch pots. They give a splendid lot of bloom the first season, but of course you can procure smaller plants and pot them on yourself.

CHINA TEA ROSES.

THE so-called China Tea Roses are becoming an important group. The exquisite colouring of the Tea-scented has been incorporated with the freedom of flowering of the true Monthly Roses, and the result is many charming kinds that stand midway between the two groups.

As the true Teas originally sprang from the Chinas, it is safe to assume that there have been many lovely tinted kinds raised in years gone by, which were discarded for the more double varieties that were then so much in request. A love of the single and semi-double kinds having been made manifest, varieties that quickly became favourites soon appeared. M. Guillot may be said to have started this race with Mme. Laurette Messimy, which remains now one of the most popular. When grown under congenial conditions it is as vigorous as the old pink Monthly, but I have not found it so hardy. Mme. Eugene Resal is even more lovely in colouring. Queen Mab soon followed the two last-named. Here, again, in growth and bud it would be difficult to see where the China ends and where the Tea characteristics begin; in fact, I have always looked upon it as a Safrano seedling, so like is it in wood and bud. Aurore is another kind of great beauty, and of even more intense apricot colouring than Queen Mab, with reddish wood. In fact, it seems like a small edition of that unique coloured Tea

Souvenir de Catherine Guillot. Mme. H. de Montefiore I much admire. This, too, is classed with the Chinas, but it greatly differs from Cramoisie-Superieure and that class of Monthly Rose. Its colour is a very charming shade, salmon-yellow, with a mixture of apricot and carmine. The buds are produced on stiff stems for this class of Rose, and they stand up well above the foliage. Cora is a very slender grower and of a delightful colour, clear yellow, tinted salmon-pink, rather small. Jean Bach Sisley is another kind of much value and large for a China. It has the colour of the crimson Monthly, but its blossoms are quite as beautiful in form as those of a Tea Rose. Irene Watts cannot be well known or it would be asked for more frequently. It is reputedly a seedling of Laurette Messimy, and in some respects it resembles that variety; its colour is a clear salmon-white, and the buds are very long and handsome. The above kinds are Chinas according to catalogues, but they well deserve the term China Teas. I should also group with them Mme. Rene de St. Marcou, Margherite di Simone, Souvenir de J. B. Guillot, Mme. Rene Gerard, Mme. Louis Poncelet, and Mme. Clemence Marchix. I do not attempt to describe the colours of these last six. They seem to defy a true description, for they possess so many tints that only a colour artist could succeed. It will be sufficient to recommend them to all who admire lovely tinted Roses, and if they obtain all the kinds named and group them together, I can promise a rich display. Procure them on the seedling Brier, plant in well-prepared beds of gritty loam, and prune hard, taking care to earth up the plants from November to April, and success is assured. Rosa.

NOTES AND REPLIES.

A useful white Rose.—There are many really good Roses that are overlooked owing to the crowd of newcomers, that perhaps are of considerably less value. Mme. Fanny de Forest is one of the former, surpassing even Boule de Neige, being minus the defects of the latter. It is of rather large size considering it is a Noisette Perpetual, the full flowers being pure white, but the blooms, just as they begin to expand, are a lovely creamy-white. It is not so vigorous as Boule de Neige. As a pot-Rose Mme. Fanny de Forest is unequalled among the white varieties, the plant flowering regularly.—Rosa.

Rose Earl of Pembroke.—This is one of the few good Roses that seem to have been to some extent overlooked by Rose growers. It is wonderfully free flowering, every shoot bearing a blossom as freely in autumn as in summer. The colour is a peculiar brownish-crimson, very bright in the bud, and the fragrance is most refreshing. I consider it one of the late Mr. Bennet's good Roses, and he gave us not a few, many of which have laid the foundation for the splendid Hybrid Teas now so popular. Earl of Pembroke is a Rose of good size, with exquisitely shaped flowers and recurved and pointed petals. It is one of the few Hybrid Perpetual Roses that can be confidently recommended for the garden.—E. W. C.

Rose Mrs. Edward Mawley.—This splendid Tea Rose well maintains the high opinion formed of it on its introduction in 1889. A fine strong grower, Mrs. Edward Mawley is an ideal Tea variety for a standard, and as its heavy blooms bend, by reason of their weight, they can be inspected and protected from injury much better grown in this way. So sturdy is the wood that some have thought it should be grouped with the Hybrid Teas, but I consider it as much a Tea as Catherine Mermet. Excepting to exhibitors of Tea Roses, I do not know that the doubt affects anybody. If the Rose grows well and yields splendid flowers in abundance, what does it matter whether it be Tea or Hybrid Tea? The salmon and carmine colour is very fresh and pleasing, and when at times it develops a yellow tint, the bloom then is beautiful.—Rosa.

Rose L'Idéal.—Among the Noisette Roses we have many kinds that are valuable in the garden or for growing under glass, the kind under notice being one of them. It is almost impossible to describe the many shades of

colour seen in blooms on a plant at one time. I have been much pleased with it for several years, more especially this one. Last year it made some long, clean, strong growths, and these, escaping the frost, gave a grand truss of bloom from each eye. These trusses had a large number of blooms on them, in some instances from 18 to 24 in a bunch. My plant is growing at the foot of a 10-foot high wall facing south. The shoots last year reached the top of the wall, blooming the greater portion of their length. In the spring I saw this on the back of a cold glasshouse, the blooms being freely produced and very highly coloured.—J. C.

CLIMBING ROSES AND THEIR GROWTH.

I have been noticing lately how much better these look away from walls, and how much I have been liable to misjudge them from specimens nailed against walls, which are often

away, the object being to insert the bud as low as possible; the stocks also run better below the ground-line. The buds and stock itself derive considerable benefit by the earth being returned again. This may remain so heaped up until next May, but it is a good plan to inspect the buds at the end of August to ascertain if they have taken; then the earth may be returned. It used to be fashionable to bud two well contrasting varieties of Roses upon one standard stock. If similar growers are selected, and also such as blossom freely, I do not see any objection to the practice. If any Rose-grower potted up some Briers last winter, he should now had these with good kinds suitable for winter blooming, as they make quite nice plants when placed into warmth in February. The grand new crimson Rose Liberty and the snow-white Frau Karl Druschki would be two ideal Roses for the purpose. In budding the main stocks, they are wisest who freely propagate varieties such as Mme. Abel Chatenay, G. Nabonnand, Caro-

Rose Mme. Abel Chatenay.—Rose growers of the old school place form before everything else in their estimation of the Rose, even praising a variety that is a wretched grower. It is gratifying to notice that the public do not follow these arbitrary canons. In Mme. Abel Chatenay the lovely blending of deep salmon-pink to a paler flesh tint towards the ends of the petals, combined with a pretty and distinct form, never fails to appeal to the eye, and when we remember it is such a splendid grower little wonder is it that the variety is being largely planted. There will soon be a fine bed of it at Kew when the plants become established, and I notice the longer shoots are tied over, which not only compels the Rose to produce more blossom, but it also induces vigorous growths from the base of the plant. As a standard Mme. Abel Chatenay makes a large head, not too compact, as is sometimes the case with standard Roses, but the long growths start out here and there with most telling effect. It is also a glorious pot-Rose, producing its blossoms upon fine long growths, but the flowers being somewhat thin a cool temperature is best for the variety. Although somewhat addicted to mildew, with care in avoiding a check or overdosing with manure the Rose can be most successfully grown even by a novice.—Rosa.

Rose Souvenir de William Robinson.—This must take a leading place among the charmingly tinted Teas for garden decoration, surpassing all other Roses of a similar colour, if there were any similar, but the fact is the novel shades of colour present in the variety give it a most uncommon appearance. The prevailing colour of the neat flowers is a rich, glowing apricot, the outer row of petals being heavily shaded rose, merging almost to crimson. There are even other tints present, but the description given will afford some idea of the beautiful colouring of the Rose. Then, too, it is such a good grower. Unfortunately one cannot say this of some of the charmingly tinted Teas now so plentiful. Where Roses are massed I would advise that a quantity of Souvenir de Wm. Robinson be planted this autumn. If not quite so vigorous as Marie Van Houtte there is not much difference, and what a delightful contrast it would be to that most useful of all Roses.—E. W.

Rose Gladys Harkness.—In fulness the flower of this leaves nothing to be desired, the grand globular blossoms, each petal prettily reflexed, being extremely showy. The colour is a clear and bright salmon-pink and the blossoms are highly fragrant. It is a fine, vigorous grower, stronger even than Caroline Testout, a Rose it resembles when opening, but more globular and double than that well-known kind when expanded. The flowers withstand rain better than many varieties.—E.

Rose Enchantress.—By all who appreciate garden Roses the above variety must be regarded as a gem. Its exquisite wedding blossoms are seen to much advantage upon standards. It is really in clumps or beds of one kind that these Roses produce the best display. The effect of Enchantress at a distance is white, but on close inspection the blossoms are a pale creamy white, the buds being quite a rich cream. The sturdy growth of the variety is quite equal to that of G. Nabonnand; the drooping blossoms, however, do not add to the beauty from a decorative point of view, but there is still this to be said about such varieties: their flowers are not so readily injured by rain.—R.

Many-flowered Rose (R. Polyantha) on margin of plantation.

hot and unpleasant surfaces for them to exist upon, and on which they cannot show their grace and where there are no coolness or light and shade to help them. The kinds I could not bear on walls I find I enjoy very much when allowed to run up trees and hang about in their own graceful way. Many of these Roses are hardy varieties of northern kinds, and in no need whatever of such walls as we must give to a Fig or a Peach in our country. I find my white Polyanthas are beautiful in cool copes. V. B.

Budding Roses.—By this time budding should be in full swing. The standard Briers are the first to be operated upon, then, following these, the seedling Briers and the Manettis. Where Brier cuttings are used they should be budded early, as they cease to grow sooner than the seedling Briers. A point to remember when budding all dwarf stocks is to draw the soil up to the roots again after the stocks are budded. Both with seedling Briers and Manettis an inch or so of the soil is drawn

line Testout, Mrs. W. J. Grant, etc., as these kinds never fail to give satisfaction, both for garden decoration and for the house.—E.

Rose Conrad F. Meyer.—This fine Hybrid Rugosa should prove of great value. There really seems to be very little relationship to the Rugosa, for in leaf and wood it resembles the Hybrid Chinese of days gone by. In colour something like Blairii No. 2, the fine bunches of flowers that crown each growth are most attractive, and have a powerful and delicious fragrance. The shape of the flower is something in the way of that of Caroline Testout and of about the same fulness. When four of the large blossoms are expanded at one time on the long very prickly growths, they present a picture of great beauty, and one readily imagines what a fine isolated bush or pillar Rose it would make. Then, too, every new shoot shows a bloom-bud which indicates its perpetual character. Altogether this Rose is a splendid acquisition, and dwellers near large towns and cities should not fail to secure

FRUIT.

FEEDING FRUIT AND OTHER TREES IN AUTUMN.

It is doubtful if cultivators give enough attention to feeding during the autumn. There is no period of growth when assistance given to the roots is of so much service. This is not difficult to understand if a little thought is given to the nature of the tree or shrub the grower has to deal with. When the soil becomes warm, with plenty of light, then growth both of branch and root is rapid. Added to this, the fruit has attained to a good size. How can these be sustained in a starved soil? But this is the condition one often sees many trees and shrubs in, and the cultivator is surprised no progress is made. This especially applies to things growing in small, narrow borders; more so if the surface has to be cropped with vegetables, etc. In many instances these have a dressing in winter, and in spring they are cropped with things that quickly take all the food out of the soil. Some may say this cropping should not be adopted, but in many cases it is almost impossible with the space and means at command, if a constant supply in the kitchen has to be kept up. In the spring months a well-known correspondent to *GARDENING ILLUSTRATED* made an important statement when speaking of trees that bore freely every year. He pointed out that it was a fallacy to suppose these would not crop yearly, provided they were well fed in summer and autumn and the crop thinned. This is the teaching we want, and if followed will bring its own reward. Every year I am more convinced of this fact, and could point to some Morello Cherries that have given an enormous crop for the last ten years, and which are still as vigorous as ever, but I do not, however, forget their needs at the roots. The same holds good with a sloping, narrow border facing south in which Apricots are growing, and the surface of which has to be cropped with early and late vegetables. This border is highly fed in winter, and when the early vegetables come off I give a dressing of a quickly soluble manure, washing it in with clear water about the time the stoning of the fruit takes place. It is astonishing the effect this has on both growth and fruit. This has been going on for nearly a dozen years, and the results induce me to continue it. Many apply manure and do not wash it into the soil, with the result that it frequently does not reach the roots till it is too late to benefit them. I prefer feeding things when growth is active to any other time, seeing it is taken up by the roots at once instead of frequently being washed down so low as to be of little service. J. CRONK.

EARLY OUTDOOR PEACHES AND NECTARINES.

BAD as the season has been for many crops, it must in all fairness be claimed a good one for outdoor Peaches, which have cropped exceedingly well and are of fine size and colour where proper thinning of the fruits was carried out. Alexander and Waterloo were ripe on July 20th, which cannot be considered bad for choice fruit in a season so proverbially late. Those in a forcing house often disappoint in a very early stage of their bud-growth, but outdoors bud-dropping is practically unknown—at least, it is so here. My trees set their fruits so thickly that severe thinning had to be adopted to save the crop. A moister and cool atmosphere has been in their favour on light and medium soils, and in some districts the rainfall has not been sufficiently heavy to give trouble in clayey land. In very hot summers Peaches and Nectarines often get scalded with the sun, and this is almost certain to happen if the fruits which have advanced for a time under the shade of foliage are suddenly exposed. For this reason it is necessary to proceed cautiously with summer pruning and training of the young Peach growth. I have seen a crop of promising fruit completely spoilt by nailing or tying the summer shoots during a spell of hot weather. No such failing has occurred this year because the sun has been tempered with cloud and showers have been frequent. Nectarines are not so extensively or, generally, successfully grown outdoors

walls as Peaches, though there are gardens where these remarks do not apply. Last summer in a large garden near Bristol I saw as fine Nectarines on open walls as in Peach-houses in the same garden.

Wasps and blue-bottle flies are troublesome to both Peaches and Nectarines outdoors, but the latter are taken the most freely when within the reach of these summer pests. The cool summer and frequent rains gave hope that wasps would be scarce. Experience, however, proves that they are not so easily controlled, for they are becoming exceedingly numerous. It is a common experience that fruit may escape up to a certain period, but with the advent of the Plum season wasps begin in earnest. It is curious, too, that no matter how many nests may be taken, their numbers do not appear to diminish, judged by the fruit attacked. Quite recently nearly thirty nests have been destroyed within an easy radius of this garden, and though this must mean the destruction of many thousands of wasps, the fruit seems to suffer as much as if nothing had been done. A partial remedy against attack was suggested by the planting of the early sorts of Peaches, which ripened their crops before wasps appeared. An evil of all insect and bird life among fruit is that they sample so many, often only so as to spoil them for every purpose, save jam-making. Only a small puncture on the surface of the fruit will set up speedy decay, whether the weather be

The common Laburnum (*L. vulgare*). (See page 255.)

suany or showery. While the planting of the early kinds of Peaches halles the efforts of the wasp and blue-bottle fly because of their early maturity, the same gain is effected in Nectarines. Cardinal has been said to be too tender to stand the frost and cold of winter and spring and was recommended as an indoor and forcing variety only. I have a young tree that has stood two winters and has shown itself quite as impervious to cold as the Peaches growing close by. This year it bore a light crop of deeply-coloured fruit, the first being gathered on August 14th. This is earlier by some days than Early Rivers', which it much resembles in colour, size, and shape. Hale's Early is a capital Peach for the open wall, giving a succession to Waterloo, Alexander, and Amsien June. The succession may not follow in the case of those having one tree only of the earliest section, but in my case having several trees, Hale's Early was ready before the last fruits of Alexander had been gathered. In writing of Alexander and Waterloo, it might be said how closely they resemble each other grown outdoors—indeed, so very marked is this that it becomes difficult to identify one from the other. Certainly there is no necessity to grow both. A good successional Peach for outdoors is Concor, which, for an early Peach, has a remarkably good flavour. Alexander, if allowed to ripen on the tree outdoors, does not offend the palate as it does forced under glass. W. S.

NOTES AND REPLIES.

Melon William Tillery.—It is several years since this was sent out, and it is very hard to beat, from a flavour point of view. Wherever accommodation can be found for them Melons in houses, this should be grown. This

year I have it growing in pots from seed many years old, and although some consider it shy fruiting, I do not find it so. My plants are carrying three or four fruits each.—J. CROOK.

A good early Plum.—All early kinds of fruit are valuable, either for home use or market, seeing that most people are seeking for change. This being so, every one who has accommodation should grow Rivers' Early Prolific Plum. It is an enormous and regular bearer if the crop is thinned. It is not particular as to position, doing well in the open or against a wall. This year I was able to gather fruit ripe enough for cooking about July 23rd, and ripe for eating August 1st, from a tree growing against a west wall. This Plum commands a good price when early in the market.—J. CROOK.

Raspberries not bearing.—Can you kindly suggest the reason for my failure to grow Raspberries? The canes were divided and planted three years ago, the ground well dug and manured. The stools have done well as regards growth and foliage, sending up a vigorous growth of canes each year. But each year they have gone off in the way shown by the enclosed specimen, blooming freely, but bearing little or no fruit, while the foliage of the old canes seems blighted, while that of the new growth is normal. The cause is not to be found in the cold of this year, for the same thing has happened every year; nor with pruning, for the old canes have been properly cut out, and four or so of the new ones left. The district is cold, the soil clay, and the garden has a slight slope to the north, but the Raspberries are in a somewhat sheltered corner.—A READER.

[We have seen similar instances of the failure of what seemed to be good Raspberry canes to fruit, and dying off, to what you mention with respect to your own, and have always found the cause to be a base of cold, clayey soil that is sour and deficient in lime. The remedy has been found in trenching the ground so as to excavate some 12 inches of the clay sub-soil, replacing it with garden refuse, road-trimmings, ditch-trimmings, turves, or similar materials of a gritty nature. A good dressing of chalk or lime should be added, with some well-decayed manure, and 4 lb. per rod of basic slag mixed with the soil before planting. Only suckers from a good healthy stock should be planted. Superlative, Harnet, or Norwich Wonder are all good ones. Practically yearling canes or suckers on your breadth do not ripen, and the soil being deficient in potash and phosphates, they fail to become fruitful.]

Planting fruit-trees on allotment.—Is it possible to obtain fruit-trees this autumn so that they will flower next season? I am thinking of Apple and Pear (espalier-trained), also Gooseberries. I am taking an allotment at the end of September, and, as one can never tell when he may be turned out, it is not worth while growing from cuttings, and perhaps having no ground for second season. I should like advice as to time and method of transplanting? Also, should I get two-year-old trees, or is it worth while moving old bushes?—J. K. S. K.

[If you plant fruit-trees of any description on another person's ground, whether an allotment or garden, except it be a nursery garden, you cannot remove them without the landowner's consent, and if you plant without his consent you cannot claim compensation for them. It is well you should know so much. If, as you say, you can never tell when you may be turned out from the allotment, it is wise to risk so much? Espalier-trees for planting in October or November, the proper season for so doing, should be three years from the bud and have been flat-trained. But, all the same, they would not be large, and may not produce any fruit the first year, and perhaps not the second. All would depend on whether any fruit spurs were formed when you purchased them, or formed the next year after planting. Gooseberry bushes would have to be hard cut back the first year, and would hardly fruit till the second or third year. Old trees or bushes are seldom worth transplanting. You can propagate Gooseberries and Currants from cuttings put in during October, but they would need two years' growth ere they were strong enough to plant out. It would be best, therefore, to purchase good two-year-old bushes of these fruits in the autumn and plant them. Of course, if you purchased four-year-old trained trees, or equally old bushes, you might reasonably hope if they did well to get some fruit from them the year after planting, but such trees and bushes would be expensive. In planting, prepare holes full large to accommodate the roots, well set out, and be specially careful not to plant too deep. When roots are fairly near the surface they can be fed as needed when carrying crops of fruit.]

TREES AND SHRUBS.

LABURNUM (GOLDEN RAIN).

ALL the Laburnums are beautiful when in bloom and quite hardy and free-growing in our country, producing fine effects if care is taken to afford them suitable positions and surroundings.

L. ALPIMUM (Scotch or alpine L.) is a native of the hill forests of France, Central Europe, reaching a height of nearly 40 feet. Many fine varieties have been raised from lime to time, one of the best being **L. Watereri**, here figured, whose spikes are often 12 inches to 14 inches long, the colour rich yellow. The Scotch Laburnum usually flowers when the others are over, and it, as well as its varieties, may be easily recognised by the broader and deeper green leaves and the rich yellow of the racemes, which are longer than those of the

Mr. J. Rose, Oxford, who sent us the excellent photograph from which the illustration was prepared, writes as follows: "One of the best Laburnums is that known as **L. Watereri**. The racemes of this variety are much longer than those of the type, being often 12 inches to 14 inches in length, and though the tree is neither so free-flowering nor produces such a mass of colour as the common one, yet its more elegant appearance entitles it to a place in any garden where more than one variety is desired."

VEGETABLES.

NOTES ON TOMATOES.

THE outdoor crop is certainly not a promising one this year; the weather, excepting about a fortnight the last week in June and succeeding week, proved far too cold and wet for the

Tomatoes require but little moisture overhead at any time, and I think if this were more strictly observed we should hear less of the disease than we now do. For the earliest crop pots 10 inches or 12 inches across are a serviceable size, leaving a couple of inches when finally potting for top-dressing, and it is a good plan if the pots are to be stood on staging to place a square piece of turf under the pot for the roots to enter to assist the plants in swelling the crop. Watering is also an important point when the roots are confined in so small a compass, examining the plants thrice daily in bright weather during May and onward, for if allowed to suffer from the want of it when once fruit is formed, the plants receive a check which no after treatment can rectify, the fruit never attaining that standard of excellence it otherwise would had the plants been well cared for from the start. By this I do not mean that water must be applied indiscriminately, far from it; too much care cannot be exercised in the matter, only giving it when you consider the plant is really in need of it. Some of the artificial manures are excellent for this fruit. For a

WINTER AND EARLY SPRING CRIP there is still time to make a start if the seeds are sown forthwith in a little heat, placing three or four in 60-size pots, reducing to one, eventually choosing the strongest, repotting into 5-inch before pot-bound, and then as soon as ready into 8½ inch or 9½ inch, which will be large enough for winter work. The soil used should be good fibrous loam with the addition of a little fresh horse-droppings put through a ¼-inch sieve, and a 6-inch pot of bone-meal to every bushel of the two former thrown together, potting firmly each time and growing on in an unheated house where the sun-heat can be husbanded about 4 p.m., with plenty of moisture about the staging and floor of the house. In a week after their final potting the plants may be stood outside, fastened against a wall or trellis, until the end of September, or even the second week in October, should the weather be warm and dry. On the other hand, if the weather prove very wet they should be put back into the house, or the flowers will fail to set satisfactorily, but our autumnals of late have been just right for plants to form fruit before placing indoors. When taken in, a south side of a span or lean-to house should be afforded them, training upwards and within 18 inches of the glass roof, and if a night temperature of 50 degs. to 60 degs. can be kept up, with the usual rise by day according to the weather, several fruits should be forthcoming from December onwards.

VARIETIES.—These are legion and most growers have their favourites. I have a great liking for Challenger and Chemin, and if a trio were required I should include Frogmore Selected, all of which will be found to give satisfaction if sown early in August, or in February for an early summer crop. I have also grown Early Ruby, which fully maintains its name; but I prefer smooth fruited kinds, as will be seen by the trio given above. If lesser varieties must be included, give Sutton's Golden Nugget and Sutton's Desert a trial.

J. M. B.

NOTES AND REPLIES.

Winter vegetables.—The latter portion of the last and beginning of the present month, being somewhat dull and showery, were particularly suited to the removal of winter vegetables, and now, as the ground is cleared of Potatoes and Peas, after being dug over stuff may still be got in. Savoys, Kale, Broccoli, and late Celery will soon get established, and if the weather becomes dry, watering should be attended to.—WOODBASTWICK.

Lettuce and Endive.—Make several sowings from now up to the first week in September of such varieties as Hicks' Hardy White and Brown Cos, All the Year Round, Lee's Hardy Green, and Hardy Hammersmith Cabbage Lettuce, keeping a sharp look out for slugs this showery weather, dusting with slaked lime late in the evening or very early in the morning. This season has been just suitable for Lettuce, transplanted stock having done well, with just a watering to settle the soil around the roots at the first start. Get a nice lot put out of each sowing, most of which

Watereri's Laburnum (*Laburnum alpinum Watereri*). From a photograph sent by Mr. J. Rose, Oxford.

ordinary sort. Besides the one mentioned there are several other forms, such as Parkesi, Carleri, and grandiflorum, while there is a drooping variety (*penulium*), a graceful tree with weeping branches.

L. VULGARE (Common Laburnum) grows freely in any soil in our gardens, the flower spikes being denser and earlier than in the alpine Laburnum. It, under good treatment, will reach a height of from 30 feet to 40 feet.

L. ADAMI is supposed to be a graft hybrid, and originated by grafting the purple-flowered *Cytisus purpureus* on to the common Laburnum. The same tree, and even the same branch, bears racemes of both yellow and purple flowers, the colour sometimes being dull purple.

Considerable judgment is necessary to plant the Laburnum effectively. Instead of dotting it about in a meaningless way, distinct groups should be planted in widely separated spots, or at least where from any given point one cannot see the tree repeated more than once. Few trees are so difficult to move when large.

well-being of the plants, and though they have made fairly good growth of late, very few flowers appear to have set, therefore it is too early to say what varieties are a success under such adverse conditions.

THE INDOOR CROP has been good in spite of the sunless spring and early summer. Those in unheated houses are a fortnight late in ripening compared with other years, but the plants keep healthy and are swelling heavy crops, which require some approved stimulant twice or so each week, removing all side growths as soon as the same can be laid hold of. Heavy bunches of fruit should be supported with string, bringing them near the glass or into as light a position as possible, partly cutting away any foliage that may shade any fruit. Where space allows, two shoals can be trained up, and I see little or no difference in the size of the fruit whether grown on the single or double cordon principle, though I know some cultivators aver the single stem gives the better returns as to size. Keep the plants dry overhead when the flowers are open—in

will be sure to come in useful later on. What is necessary in transplanting Lettuce and Endive is to preserve the tap-root, and not plant too deep. Plants of both these salads that will be required to be taken up and placed under glass as the season advances, should have plenty of space between them each way, such plants keeping much better than others any way crowded. For the large-growing kinds 1 foot or 15 inches is none too much between each plant. As regards the Moss-curl'd Endives, these are not so hardy as the Broad Batavian, so preference should be given the latter for winter work, though the curled ones look much the better when cut up with Lettuce. Where there is ample space between the Celery ridges, this will be found a capital place for sowing or planting Lettuce.—J. M. B.

Early Potatoes.—Owing to the showery, sunless weather experienced of late, the sooner early Potatoes are lifted the better, as I hear many complaints about the disease. In some cases very bad accounts come to hand, though in my own case up to now few diseased tubers have been found. In lifting the crop, care should be taken that all are clean before storing away, sorting out the seed and keeping in a cool cellar or root-store apart from the eatable ones. The sorts that have turned out best with me are Improved Ashleaf, The Puritan, Sharpe's Victor, Ringleader, and Surprise, the first and the last named having the heaviest crop and quality all that can be desired. Clean and level down the ground, when it can either be planted with Coleworts, or sown with Winter Turnips, making the soil quite firm for both, or Borecole, sprouting Broccoli, or Asparagus Kale, may still be put out. It is full late to plant out White Broccoli, as I find the earlier in July it can be planted out, the better. Late Potatoes look well, though patches of disease can be seen in the stalk, and unless warmer, drier weather soon sets in, it is to be feared disease will be very common. Nothing is gained by cutting away the haulm, as so many cottagers and even amateurs do, as soon as they detect the slightest bit of disease, ignoring altogether whether the haulm has performed its proper function to the tuber below, which it certainly has not while it remains fresh and green. It is to be regretted that no thorough cure has as yet been found for this dreaded disease to so important a crop.—J. M. B.

Asparagus culture.—I find some doubt is being felt by various gardeners as to whether the old methods of heavily manuring Asparagus must not soon be ranked amongst exploded garden practices. It is not difficult to discern, when Asparagus seed drops into unexpected places and growth ensues, that the plants in two or three years become very strong, yet get no manure dressings. I have seen numerous examples of that nature. But it must not be overlooked that such plants have none of their shoots cut from them in the way that cultivated Asparagus has to suffer, and it is fair to infer that, whilst non-cutting of spring shoots does tend to create robustness, the cutting of these shoots, especially so hard as is practised in many gardens, weakens the plants, as it is then late in the summer the ordinary top growth—the renovator of the roots—can proceed. That is a fact which has to be well considered, when it is suggested that we over-mature Asparagus beds. There can be no doubt that the old practice of placing a thick coat of cold manure over the beds or plants early in the winter is a mistake. The crowns and roots are then at rest, and, whilst hardly capable of utilising the food thus supplied, there is a tendency on the part of this manure coat to cause the roots to decay, and if that be so, then great harm is done. There can be no doubt that the most effective way of fertilising Asparagus soil is to give in the growing season occasional soakings of liquid-manure. That the roots, when in full activity, rapidly utilise, and the result is seen in fine robust top growth. Then, the stronger the season's growth, the stronger will be the shoots for cutting the following year. Light dressings of nitrate, salt, guano, or soot, under these waterings, soon wash in. This practice renders needless the objectionable course of giving the resting roots heavily with manure dressings.—A. D.

GARDEN WORK.

Conservatory.—Bouvardias, if confined to pots, should be in the pots in which they are to flower. Many gardeners plant them out on south borders or in pits where the lights can be taken off, and pot them up in September. Good results have been obtained in both ways, but success depends chiefly upon the person who does the work. Bouvardias are more easily kept clean under glass than outside, though the plants growing in the border, if well cared for, are less liable to receive checks and consequent liability to insects. The variegated *Cobra* has a pretty effect trailing and festooning about in the cool conservatory. It is specially adapted for large houses where there is plenty of room on the roof for dangling growth. Among hard-wooded plants I am very partial to the *Diosmas*, of which there are several species, all having neat, fragrant foliage, specially adapted for bouquet work or to mix with flowers in small vases. The flowers, though small, are freely produced, and are for the most part white. There is an old kind named *Diosma ericoides* I used to grow years ago, and which I should be glad to get again, but I have lost sight of it for some years. It was useful for mixing with cut flowers and so fragrant. *Diosmas* are Cape plants, and require much the same temperature and treatment as Heaths. Possibly, now that South Africa is being opened up, these and other plants from the Capo may be re-introduced again. Let me advise those readers who care for sweet-scented flowers to plant some of the *Jasmines* in the border in a light position. There are several suitable kinds, but *grandiflorum* and *gracillimum* are perhaps the best. *Daphne indica alba* and *D. i. rubra* will do well planted in a bed of loam, peat, and sand, well drained. Very often these plants have an unhappy appearance in pots, but planted out under favourable conditions they grow and flower very freely. Bamboos are graceful plants as a background, but they must not be starved in small pots, or the foliage loses colour. They are strong-rooting plants, and if it is not convenient to repot now, give weak liquid-manure. They are easily increased by division of the root crowns, and in the matter of breaking up old plants they soon make good any damage sustained when potted in good stuff.

Stove.—The nights have been cold for some time, and where *Ixoras* and other warm-house plants are grown the fires will hardly have been discontinued, but the average collection of stove plants will do very well without fires to the end of August, especially if we have bright weather, as by closing early in the afternoon some of the sun's warmth will be retained, but when September comes in it will be time to gather the warm-house plants together, and keep a little warmth in the pipes on cold nights and in damp weather. If one has room to plant a climbing plant, *Schubertia grandiflora*, something after the style of the *Stephanotis*, but with larger flowers, will be useful for bouquet work. *Ficus radicans variegata* is a very pretty basket plant that is likely to be in demand now it is getting cheaper. The habit of growth is very graceful, and when it becomes plentiful it will be useful to grow in small pots for standing along the front of the stage to form an edging. It is easily propagated in bottom-heat. *Crotons* and *Dryas* must have plenty of light now to put on colour. If shade is used at all it should be taken off in good time in the afternoon. Do with as little shade as possible everywhere now. Even Ferns will be all the better for a little sunshine during the early morning. The soft-wooded winter-blooming plants should now be in their flowering pots and be getting established.

Propagating bedding plants.—There must be no further delay now in taking a stock of cuttings of all plants required for next season. Delay now adds to the difficulties of the propagator. All the *Geranium* family will strike on a cool ash-bed in the full sunbines, and as the cuttings are of a succulent nature, too much water must not be given. The best way of striking most things now is to insert the cuttings thinly in 4-inch or 5-inch pots, using sandy soil, with a little sand on the top, and the whole pressed in with a reasonable degree

of firmness. Where space is limited, shallow boxes of manageable size may be used. All plants other than *Geraniums* should be placed in a frame or pit, where the cuttings can be kept close, except for an hour or two every morning, and be shaded when necessary. The watering, of course, must be in careful hands, as carelessness may ruin everything.

Ripening late Grapes.—This has not been an ideal summer for the Grape grower. The nights have been cold and the temperature generally below the average. With late Grapes, it is best to start early and get them forward whilst the sun has power. We may have a very bright and warm September, and this will be a great help to late Grapes, as although we may supply the warmth artificially, we cannot supply the sunshine. In many cases with *Gros Colman* and *Lady Downe's Grapes*, probably also with *Muscot*, a little fire-heat will be necessary to finish them and ripen the wood, even if we have fine weather through September.

Peaches under glass.—Sometimes young trees make too much wood. The *Muscel Plum* is the best stock for the Peach. Other stocks often lead to grossness of habit, which is difficult to correct. In making Peach borders, a free use should be made of old plaster, especially when the loam is from heavy land, which, of course, is the best for Peaches and stone fruits generally. When young trees show a tendency to grossness the best course is to lift the roots carefully and replant, adding a sprinkling of old plaster and wood-ashes. This work may be done as soon as the leaves show signs of having finished their work, without waiting for them to fall. Peaches under glass may usually be lifted at the end of September.

Window gardening.—Boxes of flowers may be kept going by giving liquid-manure once a week, and the prompt removal of faded blossoms and discoloured leaves. There will in the usual course only be a few plants in windows or rooms now, as most things will be better outside, and only those which possess some decorative value will be kept inside. Foremost among these will be *Begonias* and *Campanulas*. *Liliums* are easily grown in pots, especially the *lanceifolium* section. *Plumbago capensis* makes a good pot plant to flower now.

Outdoor garden.—Though there is no great number of trees and shrubs which flower at this season there are several which would attract attention at any season, and which ought to be in every garden. Among the most conspicuous things in flower now are the *Sumachs*, especially *Rhus Cotinus* (the Venetian *Sumach*). A good-sized plant on the lawn or in the foreground of a mass of shrubs draws everyone near for a closer examination. The *Buck-eye tree* (*Pavia macrostachya*), a miniature *Horse Chestnut*, is not so common as it might be. In a warm corner the *Ceanothus azureus* is flowering freely. Groups of *Tamarisks* and hardy *Fuchsias* in the Grass are good. *Yuccas* and the *Pampas Grass* are strong features when judiciously placed. *Hydrangea paniculata grandiflora* is very useful in any form, either as a pot plant in the conservatory or in a mass on the lawn. The *Althea frutescens* or *Hibiscus* is very distinct, and the *Escallonia*, especially *macrantha*, make a very distinct group, or may be used as wall plants. I have seen it used to form low evergreen hedges near the sea, and it seems more at home in the sea-shore counties than inland. Dwarf *Briers* and *Manettis* may be budded now, as after the rains the bark works freely. Get the buds in as low down as possible. Do not forget to sow a few hardy annuals for spring bedding, and all such plants as *Wallflowers*, *Canterbury Bells*, *Sweet Williams*, etc., should be pricked out from seed beds to get strong. Pansies may yet be sown, and cuttings taken from choice kinds.

Fruit garden.—There is plenty of scope for the fruit planter yet, and preparation should soon be made for making new plantations and filling up vacancies. There will probably be also some root-pruning to do later on, and it will be as well to look round and come to a decision as regards the work to be carried out. Any tree that is making much wood and bearing but little fruit wants a check, and that check is best given by lifting and shortening the roots, and this may be done

as soon as the wood is ripe and firm without waiting for the leaves to fall. As soon as the Peaches from any tree are gathered some of the older wood that can be spared will be better cut out. This thinning forwards the ripening of the young wood which is to bear next season's crop. Look over ripening Peaches every day to gather those fruits which are nearing maturity. The practised hand can easily tell the fruits which it will be unsafe to leave longer on the tree. Peaches for travelling must not be left on the tree till quite ripe, as a fully ripe Peach will scarcely bear handling, and certainly should not be packed for a long journey. The same remark applies to all fruits except Oranges and Pines. Any bunches of Grapes remaining in the early viney may now be cut and bottled, the house thrown open to complete the ripening of the wood, and the bearing branches shortened to further strengthen the back buds, and if the inside borders are very dry give a thorough soaking of liquid manure.

Vegetable garden.—Make a further sowing of Cauliflowers to stand the winter in frames or in sheltered places. Plant out Coleworts. Tom Thumb Savoy planted thickly now will come in useful during winter and early spring. Bear in mind, also, there is never a surplus of Spinach during the early spring months, and sow more now. Where the land is in good heart Spinach may be sown after early Potatoes without digging. Simply give a dressing of soot and a little artificial manure, or the soot alone will do. Hoe it over deeply, draw the drills 1 inch deep, and sow the seeds thinly. Turnips sown now will not get very large, but they may grow to a useful size, and will produce greens in spring. There have been seasons when Turnip tops have been appreciated. It is mainly a question of having plenty of land, and the land in good heart. Mushroom-beds in the open must be kept moist; as a rule, a little water will be required after each gathering, and the condition of the beds will tell when a heavier watering is required. A little salt in the water acts as a stimulant. When something stronger is needed urate of soda will act quickly. Beds may be made up in houses now. If woodlice are troublesome it is generally because the requisite cleaning of the house has not been given.

E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 1st.—Spring-sown Onions have been pulled up and spread out to complete harvesting. The largest will be tied up in bunches and hung up in a cool shed for use during winter. Onions cannot be kept too cool. Carnation layers are kept moist. We are increasing our stock of self Carnations, especially the Cloves. Muscas of the white and crimson Cloves are now very effective and their fragrance delightful. Cuttings of Goreniums, Fuchsias, and other plants are still being taken, and will be continued till a stock has been secured.

September 2nd.—We have been busy shifting on Cinerarias and Primulas, and we have potted up our stock of old bulbs of Cyclamens, which have been planted out in an open frame in a shady spot in good soil. They break better turned out in this way than when kept in pots, and the pots are scrubbed and made clean for use again. Some of the largest corms are several years old, and will be placed in 7-inch pots, but only the best of these old corms are used. Several heavily-laden Apple-trees have been soaked with liquid manure.

September 3rd.—Just finished repotting Arum Lilies. We have them in various sized pots for different purposes. They will remain outside for the present. Looked over the early budded Briars to loosen ties. Planted Lettuces and Endives on warm south borders. Made a last sowing of Bath Cos Lettuce. Looked over Tomatoes outside to reduce foliage a little at the bottom. All the leaders have been stopped. Herbaceous borders require frequent attention to keep things in trim.

September 4th.—Celery is earthed up from time to time, as required, though the first blanching material used in papers earthed up

being done later as a finishing process. Sowed a few more Cauliflower seeds in cold frame. Put in cuttings of the new double Arabis. This will prove a very useful border plant. It strikes freely from cuttings of the young shoots in a cold frame kept close for a time. Filled a frame with cuttings of various Eucyomuses.

September 5th.—Bottles of sweetened beer have been hung upon walls and other places to attract wasps. The nests have also been hunted up and the insects destroyed, as when numerous they spoil a good deal of fruit. Orchard-house trees in pots which require a slit have been repotted, others have been top-dressed, removing some of the old soil. Young strays shoots have been removed from wall trees and the leaders trained in. Beds are being prepared for the named Pinks.

September 6th.—New Strawberry plantations are being made to take the place of the old plantations destroyed. Alpine Strawberries are very useful now. We are potting plants for late forcing. Planted a small house with Telegraph Cucumber for winter. Cucumbers in frames are still bearing freely, and will be encouraged with liquid manure. Potted a lot of double Narcissi for forcing.

LAW AND CUSTOM.

Notice to quit garden.—Three years ago I took a piece of land (for a garden) adjoining a laundry, at 10s. per year payable in advance on the 1st April. The land was then with clay, this having been laid on when the laundry was built, and I had all this clay to remove before I got to the soil. I was under the impression that I should require a year's notice if they wanted to take the garden from me (from April to April); but I am now told that they are going to give me notice in November next to finish in May, 1903. Will you kindly tell me if they can legally do this, and if I should do any more work in the garden, or what will be the best course for me to take? Thanking you for your reply through your valuable paper.

—W. K.
[You do not say that you have a written agreement, and so I presume there is none. If this be so, the tenancy is yearly from the 1st of April and can only be determined on the 1st of April. It seems pretty certain that this piece of land is let to you as a private garden and is cultivated as such, and that it is not an agricultural holding. This being so, half a year's notice expiring with a year of tenancy will be necessary, that is to say, notice must be given on or before September 29th next (possibly it might be held good if given on September 30th) to determine your tenancy on April 1st, 1903. If the notice is not given until after September 30th, it will be bad. After you receive a good notice, you should do no more work in the garden than is necessary for the crops growing there when the notice reaches you.—K. C. T.]

BIRDS.

Canary moulting (S. E. Ilford).—Canaries and, indeed, all cage-birds require a little extra attention and abundance of food, and that of a more generous quality than usual, during the moulting season. As a proof of this it is found that birds in a state of freedom moult when their natural food is most plentiful. You may give your Canary some Maw-seed, Flax, and a little Hemp in addition to its ordinary diet, while a good supply of green food may be allowed, such as the flowering tops of Groundsel, Chickweed, or Watercress. It is well, however, to remove from the cage any green food that may remain unconsumed after a couple of hours or so, as stale green food is likely to prove injurious. It is not well to let cage-birds bathe so frequently during the moulting season as at other times, but when your Canary does take a bath, see that it is quickly dried again by placing it in the sun, or by letting it remain in a warm room. At all times guard against draughts or exposure to a low temperature—a difficult matter, often, in our changeable climate. Take care to provide grit-sand from which the bird can pick small stones to assist in the digestion of its food, and put a small rusty nail in the drinking water. This will furnish a mild tonic and assist in the elaboration of new plumage. A piece of cuttle-fish bone between the wires of the cage for the bird to peck at is beneficial at all times.—S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF *GARDENING*, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three or four specimens of each kind of fruit be sent. We cannot undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Eupatorium Wendlandi (Cory).—All the Eupatoriums require much the same treatment— that is, struck from cuttings in the spring, grown outside during the summer, and taken into a warm greenhouse in the autumn, where they flower during the late autumn, winter, and early spring months.

Carnations (Smilax).—Six for outside should include Baby Castle, rose-pink, very hardy; White Clove; Crimson Clove; Alice Ayres, light striped variety, very free; and Germania, yellow. Six for greenhouse: Pike, crimson; Herbert J. Cuthman, scarlet; Duchess of Fife, pink; Cecilia, yellow; Hermione, salmon; and The Hunter, apricot.

Sedum Sieboldi (Cory).—This is quite hardy and is frequently grown in pots. Its roundish leaves are glaucous and in autumn often assume a rosy-coral hue. The flowers are soft rose, and look well in pots, small baskets, or vases. It deserves a place in the rock garden, but, except in favoured places, it does not make strong growth. It is easily increased by division or cuttings.

Fuchsias falling (T. PatKerryll).—Draughts, excesses of temperature, and irregular watering will cause Fuchsias to behave as yours are doing, and, judging by the flowers sent, we should think your plants have been kept too wet, but, of course, we cannot positively say. We should advise you to stand your plants out of doors in a slightly shaded spot, watering, of course, when necessary, and you will then in all probability find your trouble disappear.

Woodlice (H. M. Smilax).—Woodlice are generally found in old dry dung-hills, Cucumber-frames, etc., and they are injurious to many plants, fruits, etc., by gnawing off the outer skin. If found to congregate at the base of a wall, they may be destroyed by pouring boiling water over them, or they may be trapped by laying bricks, tiles, or pieces of slate near their haunts, under which they will creep. As soon as you have planted your various things, they will soon go away if you keep the soil moist.

Echeveria retusa (Cory).—In an ordinary greenhouse this flowers in the spring, but in a warm-house it may be had in bloom during the winter. Plants that have bloomed should be shaken out during June and repotted, standing them in a cold-frame, where they can be freely exposed to the sun from the time they begin to grow, taking care not to overwater in the early stage of growth. It bears bright orange-coloured flowers, and is one of the best plants we have for room decoration during the late winter and early spring months.

Violets (J. C. H.).—We fall to grasp your meaning, unless it be that by reason of the length of stem in some single kinds someone has been tying them up to small sticks. Princess of Wales and California both have very long stalks, and it is merely a question of the variety, and nothing to do with training. In both the above, and also La France, the stems are long and the blossoms single. If these kinds were placed in the warmth of the greenhouse the stems would elongate, and at such times staking may prove a necessity.

Soil for Tulips (M. W.).—The soil you have ought to grow Tulips well if you dig in now a good dressing of rotted manure, keeping it as low down as you can. You do not say what Tulips you mean. If you refer to the Dutch Tulips, they will not flower well the second year, and must be lifted. The May-flowering Tulips may be left in the ground, but will in time retire to flower, as they will get too thick, and must be lifted and given fresh quarters. Plant the bulbs as soon as you can after the usual bedding plants have been removed, so as to allow them to root well before the severe weather comes on us.

Crassula coccinea after flowering (J. W. F.).—Old Crassulas are best thrown away after they have flowered, when cuttings have been secured, for they become "leggy" and lose most of their beauty. They may be cut back, however, and induced to make fresh growth if preferred, potting them when the pots are empty or two-thirds full, and placing them outside in a sunny window or on an arch-bed against a sunny wall during this month and the next, in order to ripen the growth, as, being very succulent, they need a thorough ripening in autumn to induce them to flower freely.

Planting Bracken (Bowie).—You may start planting at any time now, taking the precaution to leave the fronds more or less intact, or, in any case, not to submit the plants to any wholesale cutting down for the sake of appearance. If you can remove a whole spit of soil containing the rhizomes, take every care that the running end of the rhizome—i.e., the underground stem portion from which the fronds issue—does not get crushed or injured during the transplanting. It is not an easy plant to establish in our soils, though we have seen instances where the fronds have been established in quite cold clay soils.

It would certainly assist matters if some light material could be added about the roots at planting time.

Gloxinias forming too many leaves (Caution).—If Gloxinias are grown too freely and an excess of stimulants used, they are apt to run very much to leaf...

Tulips from seed (J. B.).—It is very rare for these to come true from seed, the seedlings varying in proportion with the care taken to prevent the flowers being fertilised with pollen from other sorts.

Roses for arches in Scotland (Caution).—We presume your intention is to span each of the four walks with an arch. If so, four varieties will be required, as it is customary to have each arch clothed with one kind.

Roses for arches in a cold county (M. R.).—The roses we should recommend for arches on the north side of a walk would be as follows: Queen Alexandra, Azalia, Euphrosyne, Thalia, Carmine Pillar, Mme. d'Arday, Felicité-Perpetue, Flora, Dundee Rambler, Bennett's Seedling, and Fenzance Briers.

Roses for the north (M. R.).—You will find the following two dozen really good hardy kinds, and free bloomers in the summer months.

Primula japonica (J. C.).—No hardy flower is more useful in its way for boldly massing in a shady spot or by the margin of water than this fine species, at one time considered tender.

Skeleton-leaves (Skeleton, Ayrshire).—These are prepared by simple maceration, steeping in water until sufficiently rotted to allow of the skin and soft parts of the leaf being removed from the wood fabric or skeleton of the leaf.

Perennials for border (A. M. Parsons).—The taller perennials, as a rule, require a good deal of moisture to grow them well, but many of the dwarf kinds are content with less.

grandis, and *Monarda didyma*, which may require biennial transplanting in such conditions, any of the *Hellenthus rigidus*, with annual replanting of the toes of the rhizomes.

Rose Crimson Rambler and its treatment (F. H. G.).—This Rose requires but little pruning. The best treatment is to cut away any old wood that can be spared after flowering.

TREES AND SHRUBS.

Creepers for town garden (W. Denton).—*Ampelopsis muralis*, *Cestropis pyracantha*, *C. laevis*, *Virginia Creeper*, *Vitis* in variety (particularly *dentata*, common Irish, *himalayica*, and *maderiensis variegata*, a fine silver-leaved kind), *Euonymus radicans* fol. var. (which probably surpasses the ivy in its quick growth and dense covering).

Shrubs for town garden (W. Denton).—It would have been most helpful had you given the locality, as then we should have had an idea of the elevation, which is important.

Climbers, etc. (A. Scherber of Many Years).—For west wall, we suggest *Lupinus arboreus*, *Jasminum nudiflorum* (yellow winter Jasmine), *Rose Almo* Vibert, *Tropeolum speciosum*, *Choisya ternata*, *Manisanthus fragrans*, *Eccollonia macrantha*, *Diervilla* in variety, and *Rose Fortune's Yellow*.

FRUIT.

Old Currant-bushes (W. B.).—When old Currant-bushes have fallen into the state that yours have, the most satisfactory way is to root them up and burn them, replanting with strong and vigorous trees.

Insects on Peach trees (P.).—The insects are the black aphid. Duet the trees over with Tobacco-powder, or wash frequently with soft-soap or Tobacco-water, and also wash well with clear water, using the garden-engine a short time after the other dressings have been applied.

Grease bands to prevent Codlin-moth (F. G. Dutton).—Put strips of brown paper at about 1 foot from the base of the tree round the stem, and smear these with cart grease or any sticky substance to prevent the female moths getting on to the branches.

VEGETABLES.

Green Tomato chutney (M. A.).—Put a pint of vinegar in a preserving-pan with a pound of Demerara sugar. Let this boil until the sugar is dissolved.

SHORT RAFFLES.

W. Denton.—We think it best you send this size of garden, or give some idea as to the objects you most desire to screen from wind.—*Postman*.—1, You cannot do better than fill the bed with roses.—*G. M. S.*—No, you will not be able to keep the Geraniums without heat. The *Catalpa* will winter in a cold frame.—*M. O. S.*—No, not the Violet disease. The leaves are evidently being eaten by some caterpillar.—*Corn*.—See note as to increasing *Inula phyllanthi* *miliaria* *syn.* *Clivia miniata*, in our issue of August 16, p. 327.

NAMES OF PLANTS AND FRUITS.

Names of plants.—*Cyclamen*.—*Fuchsia procumbens*.—*Alfred M. Sharp*.—1, Blue, *Campanula rapunculoides*; 2, White, *Campanula lactiflora*.—*C. S. B.*—1, *Lonchocarp*, should like to see in flower.—*L. C. M.*—1, Wild Marjoram (*Origanum vulgare*); 2, Field Scabious (*Scabiosa arvensis*); 3, Yarrow, send in flower.—*G. M. S.*—*Calceolaria*, probably *C. nigrosa*; should like to know its height and whether annual or perennial.—*B. Fielder*.—*Sedum triandrum*.—*W. Hobbs*.—*Veronica virginica*; 3, *Lysimachia clethroides*, apparently in flower.—*F. Wilson*.—Ferns: Large Fern is *Laetia*. The other is *Aspidium angulare* var. The Grasses are species of *Poa* and *Agrostis*, but cannot be named without the specimens showing leaves as well as flower. No. 6 is *Anthroxanthum odoratum*.—*M. Clay*.—Rose lilies to pieces.—*K. K. S.*—Specimen insufficient.—*R. A.*—*Henbane* (*Hyoscyamus niger*).—*W. H. Ledger*.—The Throatwort (*Trachelium ovatum*).—*E. W. Reader*.—*Ruscus racemosus*.—*Athy Super.*.—1, Red *Veronica* (*Centranthus ruber*); 2, *Clrysanthemum lacustre*; 3, *Erigeron speciosus*.—*Pizzarel*.—Black *Medicago lupulina*.—*Zany*.—Scarlet Turk's-cap lily (*Lilium chalcedonicum*). It is advisable always to send a complete specimen.

Names of fruit.—*B. Fielder*.—Impossible to form any idea as to the Apple from the specimen sent.—*T. H. R.*—*Plum Orleans*.—*Mrs. Asprey*.—We think it *Follenberg*.

Catalogues received.—*W. B. Hatfield*, Cork.—*List of Rare Dahlias and Tulips*.—*Webb and Sons*, Stourbridge. —*Bubb List*.—*W. Cutbush and Sons*, Highgate Nurseries, London. —*List of Bulbs*. —*List of Border, Tree, and Malmaison Carnations*. —*List of Strawberries*. —*Toogood and Sons*, Southampton. —*List of Bulbs*. —*Frank Dicks and Co.*, 68, Deansgate, Manchester. —*Bulb Catalogue for 1902*. —*Dobbin and Co.*, Rotheray. —*List of Bulbs*. —*Violas, Roses, etc.*—*E. P. Dixon and Sons*, Hull. —*List of Bulbs for 1902*. —*Gilbert and Son*, Dyke, Bourne, Lincoln. —*List of Bulbs and Tubers*.

"AS GOOD AS CHIVERS' JELLIES"

That is very high praise indeed for the Cambridge Lemonade, because the Jellies are recognised to be the best that can be produced. Same firm, same high standard of excellence. The Lemonade is made from Lemons and Sugar. No foreign acid added. 5jd. per bottle. Goes furthest. Ask your Grocer, or send 6d. for sample to Chivers & Sons, Ltd., Histon, Cambridge, where Chivers' Jellies are made.

FRUIT.

STRAWBERRY ABERDEEN FAVOURITE.

Is the wealth of variety to be found in Strawberries, it is not a little singular that they should almost, in each instance, possess some point differing one from another, and the variety above-named is one that may claim to be distinct from all others. The habit of the plant is robust without giving an excess of foliage, and the fruit of a brighter crimson than any other kind I am acquainted with. In Scotland, some portions of which are not well adapted to the culture of many Strawberries familiar by name in the south, Aberdeen Favourite is in much favour, by reason of its endurance of the moister climate. It is only to be expected that a variety such as this cannot be expected to succeed in English gardens to the same degree as it does further north. Even the well-established and popular Royal Sovereign does not possess this quality. Any one desirous of adding to his existing stock a variety possessing points differing from others might well select Aberdeen Favourite. In point of flavour it does not compare with Royal Sovereign or Pillbasket for sweetness, but the greater sharpness in this one agrees with some palates more than does a higher grade of sweetness. In colour and character it resembles Alice Mande somewhat, though in every respect it is distinct, the colour brighter, the fruit larger, and the plant more robust in leaf and habit. From the fact of the seeds being embedded in the flesh it is not likely to suit those who have to pack fruit for long journeys. Good travellers must have the seeds well disposed on the surface of the berry, as those protect the fruit from damage by friction. The crop this year was lessened by the loss of the earliest flowers, and consequently the finest fruits; yet, all the same, its distinct characteristics made a good impression on those who saw the ripening and gathered fruits. It is not a new variety, but is better than some of modern introduction, which have been tried and found wanting.

SUMMER PEARS.

For dessert, Pears are always popular, and in their season are in good demand. In the summer, say in July and August, there is not a large selection, and considering that there are so many other fruits available are they needed? Citron des Carmes is one of the earliest, though much of the same character and better known is Doyenné d'Ete. This is an excellent little Pear, one that must be eaten from the tree, or within a day or two of being gathered, because it so soon decays. The tree is a very regular and free bearer, and though of better colour and appearance from a wall, east or west, the fruits are good from a bush or pyramid-trained tree. In Petite Margaret we have a kind that is almost equally reliable, and bears fruit somewhat larger than the last-named. It also keeps slightly longer in a sound state, though it lacks

the pretty rosy flush on the sunny side of the fruit, and consequently loses attractiveness compared with Doyenné d'Ete. Jargonelle is another summer Pear that has many admirers. This, in size and shape, outdistances the small kinds already named, but in quality it is a matter of taste as to which is best. While the smaller sorts are free fruiters, this last-named is often very shy in bearing—especially is this so if hard pruning is resorted to. This can be grown either in bush or standard form, or as a horizontal-trained tree against a lofty wall. It is not at all suited for a restricted space, because this entails more pruning than is good for its habit of growth. Thus the lofty dwelling-house affords a much more suitable aspect than a low garden wall, and a standard gives greater area and expanse than the ordinary bush or pyramid garden tree. Another Pear in our collection which is most useful, regular in its bearing, and of nice appearance in a sunny season, is Fondante de Bihorel, a variety not often seen or catalogued. In size and shape it is similar to Doyenné d'Ete, but in its russety and firmer skin it differs much. In some seasons there is a red suffusion on the bronzed surface which enhances its value. The tree is very healthy and moderate in growth, a fact that favours regular bearing. A Pear that succeeds these is Clapp's Favourite, an extremely pretty fruit, but one that, like those already named, must be eaten from the tree or soon after. William's Bon Chretien need only be mentioned, as it is so well known. This, however, is more of a September than an August fruit, but no collection, however small, would be complete without it. Nor would it be complete without one at least of those before-named, and if only one is required then Doyenné d'Ete would be my favourite. The varieties named in this note maintain a succession from the beginning of July to the end of September, varying, if necessary, with the nature of the season.

PLANTING RASPBERRIES.

I WISH to make a new plantation of Raspberries, and shall be obliged if you will answer the following queries in your paper. What are the best kinds, and at what distance should the canes be set out, and when should they be planted?—NOTABELLO.

[Raspberries will thrive and bear fruit in almost any kind of soil that is well manured; but the finest fruit is produced by plants growing in a deep, rich loam. Raspberries produce a thick mass of fibres near the surface, and therefore are very susceptible to drought. The ground for Raspberries should be trenched 2½ feet deep, this, however, in some instances depending on the character of the sub-soil, as if it be of an inferior quality it will not be advisable to bring much of it to the surface. When trenching, plenty of manure or garden refuse should be worked into the ground. The best time for planting is as soon as the canes have shed their leaves. The

MODE OF PLANTING must be regulated by the form in which the canes are to be trained. Where stakes are available, the simplest plan is to tie the bearing canes to them, taking care that they are securely fixed in the soil. The stakes should stand out of the soil about 4½ feet,

and to each of them should be tied, when the plants have become established, five or six of the strongest and best placed canes from each stool after the fruiting canes of the previous season have been removed. Assuming that this plan of training is adopted, they should be planted in lines not less than 5 feet apart, and the distance asunder in the line should be the same, or not less than 4 feet. They will not throw up very strong growths the first year, but if the fruit be sacrificed and the canes cut to within 1 foot of the ground they will throw up much stronger canes the following season. Another mode of training consists in placing strong posts at each end of the row, connecting these with galvanised wires, strained through intervening iron standards. Thus a trellis is formed on which the canes are trained, and, if properly fixed, a plantation of Raspberries thus treated will last for years. Where this system is adopted the canes should be planted about 1 foot apart, and the shoots should be trained a little diagonally. After planting, surface dress with decayed manure. During the summer the ground must be kept clear of weeds and the soil occasionally loosened with the Dutch hoe. When the plants have become established and the young canes in the growing season have made about a foot of new wood, all useless suckers should be pulled away in order to admit light and air to such canes as are selected to remain. When the fruit is gathered the canes that have borne it should be at once cut out, so as to give increased space to those intended to bear next year's crop, and as soon as the leaves have fallen the latter should be thinned and regulated. After regulating the canes, loosen the surface with a fork, and then mulch with 2 inches or 3 inches of decayed manure, which will protect the surface roots from frost in winter and drought in summer.

Good varieties are Superlative, Baumforth's Seedling, Norwich Wonder, and Hornet, red; Guinea and Yellow Antwerp being good yellow kinds.—T. P.]

NOTES AND REPLIES.

Bark splitting (A. S. B.)—It is difficult to say positively what has caused the injury to your young trees. I was at a committee meeting the other day, where I met several of our leading horticulturists, to whom I read your letter, and they all agreed that the cause was probably frost. One stated that he had had several young trees affected in the same way.—G. S. S.

Planting fruit-trees.—Having just bought a house in this locality, I am desirous of planting in the garden some fruit-trees, and am venturing to ask your assistance as to the sorts suitable to the soil, which appears to be light, rather dark in colour, and, I think, marl and chalk as a subsoil. What sorts of Apple-trees, cooking and dessert, both late keepers, would be the best? Also Pears and Cherries?—OCTRAH, Croydon.

[Your soil seems to be a suitable one for fruit-trees. Certainly they do very well in your locality, if not too much in the heart of the town. If you have any walls to your garden you can plant on the south aspect, or walls facing south, an Apricot, Amsden June, and a Royal George Peach, and an Early Rivers' Cherry. On west or east walls, plant Green Gage and Monarch Plums, or Marie Louise and Winter-Nelis Pears, and on the north wall Catillac baking Pear and Morello

Gooseberry Green Champagne.

Charries. Of course, these would have to be flat-trained trees obtained from a nursery, and would need good attention in pruning, training, and nailing them each year. If you want trees out in the open ground only, plant bush Apples of such varieties for late keeping, as Cox's Orange Pippin, Cockle Pippin, and Starmer Pippin, and of cooking varieties, Waltham Abbey Seedling, Wellington, and Lane's Prince Albert. Pear trees should be of bush or pyramid form, and may be for late keeping, Josephine de Malines, Bergamotte Esperen, and Easter Beurré. The best Pears, however, ripen in November, such as Louise Bonne, Doyenne du Comice, and Durondeau. Good Plums for bushes or dwarf standards are Victoria, Monarch, and Wyedale, cooking. Good dessert Plums are Green Gage, Jefferson, and Kirke's, but these fruit best on a wall. Good bush Cherries are Elton, May Duke, and Black Tartarian. These would, however, whether on a wall or as bushes, need to be well netted from the birds. Bush trees should be planted fully 12 feet apart, to allow ample room, and it will be well to get the ground ready for planting in October, then plant so soon as the trees can be obtained.]

Pruning fruit-trees.—I should feel obliged if, in your next issue, you would kindly state the best time to prune Apple, Pear, and Plum-trees (standards). Some say early August (summer pruning), others say not till November—December. I have some very healthy pyramid Pear-trees, but get little fruit from them. They were pruned last December. At present they are covered with a very strong growth of new wood, and the question is, whether it should now be cut well back to the second or third eye for next year's fruit-bearing?—D. P. MAY.

[Standard fruit-trees, whether Apples, Pears, or Plums, once the heads are well formed, after, say, three years' growth, simply need occasional thinning, although should any one or more branches grow too strong those can be shortened back to keep the head of the tree fairly well-formed. The best time for doing such pruning is in October or November in dry weather. If done yearly, then the thinning need be slight and the trees suffer no check. If the heads be left untouched for two or three years, so that they become denser, then a severe thinning is needed, and the tendency of this

Plums. Will you kindly give me the names of sorts most suitable, and which will give good shade for the fowls? I thought of putting about three trees in each run. Ought they to be on the Paradise-stock or Crab-stock?—M. W.

[Plant standard trees only in your fowl-runs. They will be in the form of heads on clean

stems from 5 feet to 6 feet in height. That will keep the heads and fruit quite out of the reach of the fowls, which must have one wing clipped if they take to flying up into the trees. Standard Apples are always on the Crab-stock, Pears on the Pear-stock, and Plums on the common Mussel-stock. The trees should be planted from 12 feet to 16 feet apart at least. Of Apples, for your purpose plant of kitchen or cooking varieties, Duchess of Oldenburg, Manks' Codlin, Warner's King, Waltham Abbey Seedling, Wellington, and Lane's Prince Albert. Of dessert varieties: Irish Peach, King of the Pippins, Fearn's Pippin, Cox's Orange Pippin, Cockle Pippin, and Starmer Pippin. Of Pears: Williams' Bon Chrétien, Louise Bonne of Jersey, and the stewing Pear Catillac. Of Plums, have Victoria, Rivers' Early Prolific, Czar, and Monarch, with Farleigh Prolific Damson. Order your trees from a good nursery at once, and get them planted, if possible, before the end of October. Plant shallow, with the roots well spread out, but all the same have large holes for each deeply broken up. Add in planting just a little well-decayed manure. Feed chiefly from the surface after planting. For a time, until the soil about the roots becomes firm, you will have to place bushes or other protection over it to keep the fowls from burrowing into it. In time fowls, if well fed in their runs, practically manure the trees. Especially do fowls eat up any insect life that may harbour in the soil, and this helps to keep the trees clean

is often to cause the trees to respond by again throwing out too much wood growth. When from main branches a quantity of shoots is thrown up each summer it is folly to allow those to remain and make all possible growth, just cutting them out again in the winter. Far better, with some leather gloves on the hands, rub them clean out whilst they are young, and then they may yet grow again. With respect to your pyramid Pear-trees, you had better at once summer prune, although it would have been better done rather earlier. Cut back at once all side-shoots on the branches to three or four leaf-buds, and just stop or shorten the leader or extension shoots to each branch. That operation should result in causing the leaf-buds of the shortened shoots to plump up, or become partially changed from wood-buds, which they would simply be if left untouched, into semi-fruit-buds, and next year they become true fruit-buds or spurs. In the winter you would have to go over the trees again, and shorten each cut-back shoot to two buds, so as to keep the fruit-spurs as close to the main stems as possible. If this process of summer pruning fails to make the trees fruitful, then you will have to try the effect of root-pruning on them.]

Fruit-trees for fowl's-run.

—I wish to plant my fowl-runs with fruit-trees. The runs are Grass about 25 yards square, soil light and sandy. I want Apples, Pears, and

Properly support each tree with a stout stake a few weeks after planting.]

THE BEST GOOSEBERRIES.

How often one hears the question asked, "What are the best Gooseberries to plant?" But the quorists seldom state the uses to which they wish to put the fruit, consequently they have to be questioned in turn before the desired information can be afforded. As is well known, there are a great number of varieties of Gooseberries, some of which attain a large size when mature. Others, again, are only medium-sized when ripe, and some are but small. With one or two exceptions the last-named furnish the richest-flavoured fruits among Gooseberries, some of them being green when ripe, others yellow, and some red and white. If Gooseberries of first-rate flavour, irrespective of size, are required, it is from amongst the varieties to be presently named that a selection should be made, and no garden is complete unless these delicious though small-berried kinds are represented in such numbers that a daily supply may be afforded as long as the fruit is in season. Among the medium-sized fruiting varieties we have what may be termed useful Gooseberries—i.e., the berries may be put to such uses as the bottling of these in a whole condition, and the making of a preserve, either while the fruit is green—which method finds favour with many—or when nicely ripened. Some of these (Gooseberries, too, are well flavoured, although not so rich as those already alluded to, and are consequently of great service when a good demand has to be met. Among the large-fruited kinds are those which are fit for gathering before any others in the spring, and are therefore very valuable, both from a market grower's as well as a private consumer's point of view. The large exhibition kinds also belong to this section, but these being outside the scope of this note, they will not be further alluded to just now. We therefore have what may be termed three classes of Gooseberries, the one for affording early supplies to be gathered in a green state for cooking, the next, or the medium-sized fruits, alike valuable for bottling, preserving, and general utility purposes, while the small kinds are the highest flavoured, and, therefore, most suitable for the dessert.

LARGE-FRUITED KINDS.—Taking the large fruits, and those that come in for gathering

Gooseberry Whitesmith.

early, it is questionable if Whinham's Industry taken all round—has a superior. Once they are set the berries quickly grow to a good size;

the bushes are strong growers and bear very heavily. Keepsake is preferred by many growers to the foregoing, but my experience of it is that it is not quite so early, but soil and position may perhaps account for this. Be this as it may, it is a valuable early kind, and is considered by some to be synonymous with a variety named Berry's Early Kent, but this is

PLANTS AND FLOWERS.

ROSES

REPOTTING ROSES.

(REPLY TO "HORTULAN.")

Your plant is starving in such soil as you send and must be repotted. Roses when repotted must not be dry at the root. A compost is prepared as follows: Two parts fibrous loam, one part well-rotted manure, one year-old cow-dung being best. Mix this well together, then incorporate a 5-inch potful of some good artificial manure in each barrowload of soil. The pots must be well washed, also the crocks. Oyster-shells make fine material for crocks. On to the latter (which must be plentiful) a thin layer of well-rotted manure is placed, then a little of the compost, and all rammed firm. The plant to be repotted is turned out and laid on the potting bench. Remove the crocks carefully, and if roots are abundant the plant needs repotting, otherwise return it into a similarly prepared pot, which, of course, must correspond in size to that from which the plant was taken. When the roots are plentiful, gently release them and remove the outer crust of soil all over the ball with the end of a pointed stick.

Take the ball in both hands and give a good, vigorous shake, and by this time sufficient of the old soil will have been removed. If the plants have not been repotted lately, more of the old soil should be shaken off, but be very careful to preserve all roots. When the ball is thus prepared, place it in a pot one size larger, and fill up the sides with the new compost, making this run down freely by using a thin label. A thicker but flat stick is now brought into use, which rams the soil well down. It is the little details which tell in gardening as in other things. If a cavity is left around the ball serious mischief is caused, and this is very likely to happen when a pot only a size larger than the previous one is used. After potting stand in full sun on a bed of ashes, and should the weather be dry the plants must be watered with a rose can after

sides during November, partly to ward off excessive rains and partly to prepare for covering over should frost occur. A few degrees of frost will not harm the Tea Roses, but 9 degs. or 10 degs. will seriously injure the pith, so that unless one can well cover over with mats, remove the plants to an airy glass structure.

BUDDING ROSES.

I SHALL indeed be grateful if you will kindly furnish me with instructions for securing Rose-buds for grafting on Brier-stocks. I find it so difficult to remove the wood or pith without injuring or removing the eye from the bud. Please describe what shoot and the age thereof I should select for taking buds from. Would soaking the buds with the wood on for a few hours render its removal easy without injuring the eye? If part of the eye is left in the bud, would this suffice, or must the eye be intact? How can I tell when a shoot has well-seasoned wood suitable for taking buds from?—CONSTANT READER.

[It is not at all difficult to secure the proper kind of wood for budding the Hybrid Perpetual and many of the Hybrid Tea Roses, but the true Teas require careful watching as the eye or bud quickly starts into growth, and is then not so suitable. We always prefer shoots that have blossomed or upon which the flower is opening. They are then in their best condition, and you should experience no difficulty in removing the wood. Upon established plants the eyes or buds of both Teas and Hybrids do not start into growth nearly so quickly as they do upon young or maiden plants. One may obtain suitable wood from most kinds, even after the flower has opened several days, but in some cases it is necessary to take them even before the flower is fully expanded. The shoots must not be so dry that they require soaking, and this is never necessary excepting in very rare cases. We have inserted buds even without removing the wood at all, and they have "taken," but we do not commend the practice. It is most important for successful budding to see that the stocks "run" well—that is, the sap should be flowing freely. It is useless to bud if the bark does not open freely. The safest method to adopt to remove the wood from the bud is to press the thumb nail of the right hand into the wood just above the eye, and with the left hand raise the wood and pull it towards the right hand, when it will snap off near where the thumb nail is pressed. Now change the bud into the left hand and raise the wood from the other end. It will then come

Gooseberry Crown Bob.

a matter that should be cleared up, as in some fruit lists Keepsake is given as a red kind and others yellow. I have always known it as a yellow fruit, and it grows to large dimensions if allowed to ripen, as does Whinham's Industry also. The old Crown Bob is also still largely grown for early and market supply, and large quantities of it find their way to Covent Garden Market. A new variety named May Duke is spoken highly of, and said to be a valuable early variety, but not having grown it, I am not in a position to offer an opinion as to its merits. Those about to plant should not fail to give it a trial, and be sure to include Whinham's Industry and Keepsake in such numbers that the supply will rather exceed than meet the probable demand. Among the

MEDIUM SIZED KINDS, we cannot well dispense with the old Rough Red, as this is generally considered to be the best of all Gooseberries for bottling in a green state. Scotch Nutmeg is a good substitute for it, but it is not such a heavy cropper. Lancashire Lad, Wilmot's Early Red, Red Warrington—the last indispensable for late supply—and Keen's Seedling are four good reds. Glenton Green, Gretna Green, Green Walnut, Langley Green are four good varieties of that colour. Bright Venus and Snowdrop are white, while Early Sulphur and Yellow Ball are also to be recommended among the medium-sized yellow kinds. Turning next to the

SMALL-FRUITED KINDS, we have Ironmenger, Early Red Hairy, Red Champagne, Small Rough Red, Pitmaston Green Gage, Green Gascoigne, Early Green Hairy, Hedgehog, Yellow Champagne, Golden Drop (see illustration), Rumbullion, and Yellow Ball. These are undoubtedly the best in this section, and cannot be excelled for flavour. Those who would like to grow sixteen of the best of large-fruited varieties, should select Criterion, Catherine, Langley Beauty, Leveller, or Guinea among the yellows; Antagonist, King of Trumps, Lancer, Hero of the Nile as whites; Conquering Hero, Dan's Mistake, Speedwell, and Lord Derby as reds; and Stockwell, Telegraph, Thumper, and Matchless as green kinds. A. W.

Gooseberry Golden Drop.

Photographs of Gardens, Plants, of Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. J. H. Taylor, Little Trinity, Cambridge, for Phyllocactus White Hybrid; 2, Geo. E. Low, for Dimorphothecca Eckloni.

the first three or four days, but only resort to artificial watering when really necessary, or the soil becomes too much compressed for the new roots. If it be desired to retard the Roses as much as possible, keep the plants outdoors so long as frost keeps off, but we are rarely safe after October. Lay the plants on their

sides, and leave the germ of the eye or bud intact. Cut a few shoots of a common Rose or Brier and practise this removal of the wood before you commence budding. If the shoots are in the proper condition—that is to say, half ripe—you will soon be able to remove the wood without difficulty. Do not insert any

bud where there is a hole left beneath the bud after the wood is pulled out, as this is a common cause of failure. There should be a small portion of wood beneath the eye about the size of a pin's head, which in reality is the germ of the bud, and it is of vital importance to see that this is not removed.]

NOTES AND REPLIES.

Roses on own roots.—Last autumn my gardener took about three dozen cuttings of Hybrid Perpetuals, which he simply placed in the ground and made firm. Out of the three dozen only about two have failed, and the others are quite large plants, from which I picked off many buds. The position was shady and damp. Do you think cuttings of H. Teas would answer as well treated in the same manner?—MR. PALMER, *Naburn Hall, York*.

[Yes, they will strike as readily as the H.P.'s, with which you seem to have been very successful.]

Rose Aglaia.—By your advice, about three years ago I planted an Aglaia Rose, together with two Crimson Rambler and a Flora, over wire arches planned to form a Rose temple. Till this year the Aglaia has not flowered, and even now has only had a few small clusters, but it has made enormous growth. I am writing to ask if this growth should be cut back heavily to make it flower, and what time is most suitable for doing so? If it does not flower more freely I shall cut it down, as it takes up much space without any result. An Electra Rose I put in only last autumn, though a tiny plant, had eleven trusses of bloom. If from your experience the Aglaia never blooms freely, even after pruning, I will cut it down at once and so lose no more valuable time. The Crimson Rambler has been ever since planted a sheet of bloom. I must own to being rather disappointed with Flora, which seems to have rather a poor little flower, though it certainly has improved this year.—MRS. PALMER.

[No, thin out the weak wood and so allow the sun to ripen the growth that is left. Your Rose is too thick, hence the failure to bloom. Unripened wood will never give a profusion of bloom. See reply to "T. H. G." re treatment of Crimson Rambler in our issue of August 30th, page 358.]

Preparing beds for dwarf Rosess (Wilfred).—Unless your soil is badly drained, it will not be necessary to raise the beds for the Tea or Hybrid Tea Roses, but you must take care that the drainage is ample when preparing. This you can do by well breaking up the sub-soil with a fork. Some broken bricks, large stones, or corks to a depth of 6 inches placed about 2 feet to 3 feet below the surface would provide sufficient drainage, but this would only be necessary if the garden lies low and water passes away slowly. The Hybrid Teas generally should be regarded as Teas. They, like the latter, prefer a somewhat porous soil, therefore a fair amount of grit should be well incorporated with the staple soil. You must, however, plant firmly, and see that the roots are not cramped, carefully place them in the hole, and work in some fine soil among them before treading. As you desire to plant rather thickly, you may place the majority of varieties now grown 1 foot 6 inches apart. Kinds marked "moderate" in catalogues may be planted 1 foot apart, and those marked "very vigorous" should be 2 feet apart. By planting thus, you are enabled to prune away much of the old wood each season, and the quality of blossom obtained from the previous season's wood is of the best description. The dwarf-growing Polyantha Roses should be planted from 12 inches to 15 inches apart. If you desire to keep them very dwarf, you may prune close to the ground each year, otherwise treat them as Tea Roses.

Rose Frau Karl Druschki (H.P.).—The marvellous results obtained by cross-fertilisation become more manifest each succeeding year. Herr Lambert, of Trier, Germany, is to be congratulated upon the production of this splendid Rose. It must prove of great value both as a cut flower and for garden decoration. It is magnificent in form in the half expanded state, but is not excessively double, for in this case the full blown blossoms open out like a huge semi-double Peony. It is the snowy purity of the blossoms that gives the Rose its chief value. Hitherto we had no large-flowered Hybrid Perpetual so pure in colour. It is really remarkable that the variety is such a dazzling white, for one would expect a seedling from Merveille de Lyon and Caroline Testout to have a shading of blush or pink. The only colour perceptible is on the outer petals of the buds, which are tinted rosy-pink, but when the high-centred half-open flower is developed it is of the purest white. It is a splendid grower, maiden plants making shoots each 4 feet or 5 feet long, and it appears to be thoroughly perpetual, as every shoot shows a bud. Frau Karl Druschki will be a grand pot Rose, and the fine long

which are produced will add further to its usefulness. There are few Roses but possess some defect, and it is only right to mention the fact of an utter want of fragrance in this Rose. I prefer fragrance in a Rose to any other quality, but I cannot shut my eyes to the usefulness and beauty of some of those that are deficient in this attribute.—Rosa.

Rose Ben Cant.—This splendid Rose will undoubtedly take a foremost position among show Roses. I am told it is a cross between Suzanne Marie Rodocanachi and Victor Hugo, and one need not be informed of its relationship to the former, as it is so patent from the splendid shell-like petals. The variety inherits the glowing colour and pointed, high-centred form of Victor Hugo, but is apparently a stronger grower than either of the parents. This Rose has been awarded the highest honours obtainable—namely, the gold medal of the National Rose Society and an award of merit from the Royal Horticultural Society.—C. W.

Rose Gardenia.—I have been agreeably disappointed with this Rose, which proves that a hasty judgment of Rambler Roses is to be deprecated. I imagine it will be possible to raise a fine variety from it in course of time. Even now the flowers of Gardenia are some 3 inches in diameter, of a beautiful pale yellow colour, expanding to sulphur-white as in Solfaterre. The buds are charming, produced singly in most cases, but not infrequently in twos and threes, and of the tint of Perle des Jardins. When gathered they are scarcely distinguishable from Tea Rose buds. The only drawback from these valuable running Roses is their want of a perpetual flowering character, so that, of course, they are not comparable to the Teas and Noisettes, but there is this to be said of them—they appear to be exempt from mildew, and spring frosts do not harm them; at least, that is my experience of the Rose under notice, and also of Jersey Beauty. I would particularly recommend Gardenia as a pillar Rose and for the supports of a lofty pergola where it will receive plenty of sun. This and Jersey Beauty are much too good to be planted where perhaps they will not receive that attention which their merits entitle them to. If a position could be prepared after the style of that at Kew, then I would say plant these two freely. In this dell garden many loads of really good soil were placed before a Rose was planted, which explains why the Crimson Rambler and other glorious kinds are in such a flourishing condition.—Rosa.

Very dark Roses.—One is frequently asked to recommend a good dark Rose that is satisfactory in growth and bloom. Undoubtedly Prince Camille de Rohan is the best very dark Rose we at present possess, and truly splendid it is when well developed. It requires high cultivation in order to bring out its good colour, for when neglected or in poor soil the flowers are quite a light red hue. Although standards or half-standards seem to yield the best blossoms, I have had lovely flowers from the seedling Brier. It roots freely from cuttings, but the flowers seem to require powerful root action to bring them to perfection. La Rosiere is bracketed with Prince Camille de Rohan as being too much alike. This they are when in blossom, but I find the former the freest bloomer on young plants, which indicates that the two kinds are not exactly synonymous. A cool season suits the dark Roses best, the beautiful velvety shading being very lustrous. It is an excellent plan to dig in a liberal dressing of good farm-yard-dung about the end of November, and at the end of May, when buds are swelling, give a good watering once a week of liquid-manure, if possible from the cow-yard, and it may be given of good strength if the plants are well established. Abel Carriere is another good dark Rose, which is best from standards or half-standards. The form is imbricated, and, from an exhibitor's standpoint, less meritorious than the last-named. At times, however, the rich maroon colour is very intense, the half-expanded flowers being superb. Both kinds should be in every fair-sized collection, and if a third is wanted I should name Baron de Bonstettin. In all three cases vigorous growth is required, and a severe clearing away each year of the old wood, the one-year-old being retained a good length.—E.

INDOOR PLANTS.

THE ZONAL PELARGONIUM FROM SEED.

To those who have been careful of their seed when ripe, now is the time to sow it, provided, of course, there is ample accommodation to keep a few hundred plants through the winter, and this means also that the temperature must not go below 45 degs. Prepare a seed-pan or box in the usual manner, filling it with good fibrous loam, freely mixed with sharp, gritty sand and a little leaf-mould, if properly decayed. The seed, being of a light, flaky nature, should be thoroughly dry, otherwise it cannot be scattered evenly. After sowing cover the seed with fine soil to the depth of $\frac{1}{2}$ inch. Cover the pan with a square of glass and place in a corner of the stove or fernery until germination takes place. When the tiny plants have made two or three pairs of leaves pot them singly into thumb-pots, using soil similar to what they were sown in. Some recommend a little bone-meal or guano, but I think that stimulants, in any form whatever, only retard the blooming period; in fact, I have seen instances of plants three years old failing to bloom owing to their being fed with manures in different forms. After all are potted keep them on a nice warm shelf in the greenhouse, when rapid growth will be made through the autumn. At the end of January shift them into the 4 or 4½ inch size, using as a compost three parts good yellow loam, one part sharp sand, one part well-decayed leaf-soil, mix thoroughly, adding a 6-inch potful of soot to a barrowload of soil. Pot the plants very firmly in these, and the result will be short jointed growth. No pinching or stopping should take place, allowing the plants to grow naturally throughout until they bloom. After the last named pots are full of roots the plants may receive the final shift into pots 5½ inches in diameter, in which they will flower, and in many cases show a pleasing diversity of colour and form throughout. If these plants are shifted on the next spring into 7-inch or 8-inch pots delightful specimens may be had from 3 feet to 4 feet high, providing an abundance of bloom for a long time. When the plant is beginning to bloom a little liquid-manure should be given each week, taking care to keep it on the weak side. D. G. McL.

Bridge of Weir, N. B.

WATERING SEEDLINGS—A NOVEL IDEA.

A SIMPLE experiment which I have lately tried here may be of interest to your readers. I do not know if the idea is new to you, it is so to me. I placed a board across a greenhouse tank nearly full of water, and on this board placed two flower-pots (48's) containing an ordinary compost, with broken crocks, etc., at bottom as usual. Into one of these I inserted the ends of two pieces of flat lampwick, about an inch wide, close against the side of the pot and extending to the bottom inside—i.e., between the compost and the pot. The other ends of these two pieces of wick simply dipped into the water. In the second pot I used no wick. This was done three or four weeks ago, and during the whole of this time the contents of the pot in which the wicks are used has been uniformly quite moist (too moist for most things), while the compost in the other pot is absolutely dry. I have not proceeded further in the matter as yet, but am well satisfied with the result so far. The method appears to me to be of wide and useful application, especially for such purposes as that of raising Ferns from spores, where it is so important that the spores should be undisturbed by the somewhat violent process of watering. The degree of moisture to be attained under the above method admits of perfect control, and is uniform and constant by day and night. The number and size of the wicks may be varied at will. There is also a practical guarantee that the water thus taken up from the wick by the compost is of the same temperature as the surrounding air. There are also an obvious saving of time and a avoidance of any evil consequences arising from

neglect. It will be seen that it is desirable to keep the tank fairly full of water so that the height to which the water must be raised by the wicks shall be as small as possible.

Woking. HOUSTON STEWART.

HYBRID PHYLLOCACTI.

WITHIN the last few years interest in the showy-flowered members of the Cactus family has been considerably revived, and they are now more extensively grown than was at one time the case. True, the individual flowers do not last long, but a succession is kept up for some time, and they are so gorgeous when at their best as to fully compensate for any failings. They are essentially everybody's plants, for they can be grown in the window of the cottage quite as successfully as in an elaborate glass structure. The cultural requirements of these members of the Cactus family have been so often dealt with in GARDENING ILLUSTRATED that little need be said on that score, except to point out that a soil composed principally of good loam, with an admixture of brick-rubble, sand, and well-decayed manure, suits them well. They are all sun lovers, and should be fully exposed thereto, except when in flower, as the blossoms remain

INCREASING GERANIUMS, ETC.

Will you kindly publish an article dealing with the propagation of bedding-out plants—e.g., Geraniums, Calceolarias, Lobelia, and Pyrethrums—and their care during winter?—H. WALKER.

[No time should be lost in going over the beds and taking all the cuttings of Geraniums that can be spared without disfiguring the plants. Cut off just below a joint, and remove the bottom leaf, not by stripping it downwards, but by cutting it off near the stem. Then remove the scales from the portion that is to be buried in the ground, otherwise they are apt to prove a seat of decay. A length of 4 inches to 5 inches is a suitable one for the cuttings, which, if they are very succulent, may be allowed to lie on the bench a day before insertion. In carrying this out a couple of inches of the stem may be buried in the soil. Some prefer boxes and others pots for the cuttings, the pots being in many ways more convenient than boxes, and they may in the winter when space is limited be stood here, there, and everywhere. Pots 5 inches in diameter are very suitable for the cuttings. The pots should be quite clean and crocked with a few broken potsherds. Then fill the pot with light sandy soil pressed down moderately firm, and put six or seven cuttings in a pot.

frosts. Failing a frame, as above, the cuttings may be struck in pots and wintered in the greenhouse, choosing a spot as far away as possible from the hot water pipes. In the spring pot off singly. Lobelias were at one time struck from cuttings, to obtain which the plants selected for propagation had all the flowers cut off about the end of July, and the young shoots then produced were struck in a close propagating case and wintered on a greenhouse shelf in a dry atmosphere, as they are very liable to damp off at that season. Now, seed is so carefully saved that a very uniform batch can be raised in this way; in fact, it is the method now generally employed. The seed is sown in a gentle heat early in March, the seedlings pricked off when large enough to handle, and either potted into small pots or planted a couple of inches apart in large shallow boxes, from which they are carefully lifted for planting out. Pyrethrum is raised from seed sown in the same way as the Lobelia.]

NOTES AND REPLIES.

Treatment of Fuchsias and Hydrangeas after blooming.—I should be glad of your assistance as regards the following: What is the correct method of treating greenhouse Hydrangeas and Fuchsias after blooming in respect to (a), should they be placed out-of-doors until late autumn? (b), do they need much water now or during winter? (c), when and how should they be cut down?—H. WALKER.

—How ought I to treat my Hydrangeas after they have finished flowering? How much pruning is required?—J. W. F.

[(a) If your Fuchsias and Hydrangeas have done blooming stand them out-of-doors in a spot fully exposed to the sun in order that the wood may be thoroughly ripened. (b) Continue to water as before till the leaves show signs of falling, when less must be given. In the winter stand them in an ordinary greenhouse where they are just protected from frost and nothing more. The Hydrangeas may, if you prefer it, be wintered in a frame and covered up in the winter to keep safe from frost. The Fuchsias will need very little water till the end of February, but the Hydrangeas will require a little more. (c) Just before the Fuchsias start into growth—that is, about the end of February—they may be trimmed into shape; but the Hydrangeas will not need any pruning unless there is a tendency for the centre of the plant to become crowded up with weak shoots, and if so they may be thinned out in the winter.]

Hybrid Streptocarpus.—The freedom with which the Hybrid Streptocarpi bloom, and their varied colours, commend them to all lovers of greenhouse plants. Their blossoms also lasting long when cut, is another point one cannot afford to lose sight of. They may be grown with the ordinary greenhouse plants, and do not require so much heat as many imagine, the extra care being needed in the winter-time, when damp is one of their worst enemies. Seed may be sown in March or April in heat, or a sowing can be made now, and as the seeds are very small care should be exercised, just covering them, and no more, with sand, and placing the pan under a propagator where bottom-heat can be obtained. Those who grow (Hoxinias will have no difficulty with the Streptocarpus.—LEAUFST.

Geranium Mrs. R. Parker.—There are few finer subjects for pot culture than this Geranium. Like all the variegated kinds, it is less liable to lose its leaves in winter than the plain-leaved varieties. Why this should be so I cannot say, but it is a fact, and one that is of some importance to window gardeners whose plants cannot enjoy the same advantages as when grown in glass-houses. The old variegated kinds, such as Flower of the Day, and which for many years have been so largely used in the flower-garden, are not effective as flowering plants, but Mrs. R. Parker is quite as remarkable for the beauty of its flowers as for its foliage. The large trusses of double soft pink flowers are very striking, and they are produced freely, well-grown specimens carrying a dozen or more trusses. Some appear to find a difficulty in inducing this variety to flower freely—the plants making strong growth but failing to form buds. I find the best way is to grow them liberally through one season, get them well established by winter, and starting in spring.—BYFLEET.

A hybrid Phyllocactus. From a photograph sent by Mr. J. H. Taylor, Cambridge.

fresh for a longer period if shaded at that time. Very little water will be needed during the winter months, though in the summer more may with advantage be given. Lastly, a structure with a minimum winter temperature of 45 degs. will suit these Phyllocacti well. As illustrating the increased interest taken in flowering Cacti, it may be pointed out that at the Temple Show the group of these plants annually exhibited by Messrs. Veitch is usually surrounded by hosts of admirers. By continually raising seedlings and selecting the best therefrom, there is now quite a large number of these hybrid Phyllocacti, ranging in colour from white, through various shades of pink to a rich scarlet shaded with magenta, and overspread with a more or less metallic lustre, which appears to be of different shades, according to the standpoint from which it is viewed. A selection of the best varieties would include: Agatha, bright red, purple centre; Brilliant, vivid scarlet; Cooperi, creamy white; delicatus, light pink; Ena, orange-scarlet, shaded apricot, purple margin; Isabel Watson, particularly fine, the outer part of the flower dark coral-red, with an orange-red centre lit up with violet; Olivette, rose carmine; Plato, brilliant scarlet; Syrens, soft salmon-pink, with a darker centre; Venus, crimson, shaded violet; and Vesta, white.

They may then be stood out-of-doors on a hard bottom, and in a spot fully exposed to the sun but sheltered from the wind, and when necessary watered through a fine rose. They may be left there, as a rule, till about the second week in September, when they must be removed to a light, airy shelf in a greenhouse or some similar position. If you have plenty of room you may put the cuttings under glass now, and as soon as rooted pot them singly into 3-inch pots. Throughout the winter only sufficient water to keep the soil slightly moist should be given. Those that are wintered in stores must be potted off singly early in March in order to get them well established before bedding time comes round. The old bedding plants, too, may be lifted in the autumn, and a good many of the large succulent leaves cut off. Then pot them into small pots, and in a dry house they will pass the winter well. Calceolarias are propagated from cuttings put in towards the end of August. They are rather impatient of too much fire heat during the winter, hence they are usually dibbled into an ordinary garden frame, into which a few inches of sandy soil has been put for that purpose. In the event of hot sunshine they will need shading till rooted, after which plenty of air must be given whenever possible, while the frame must be well protected during severe

OUTDOOR PLANTS.

PLANTING HOLLYHOCKS.

(REPLY TO "E. P. S.")

The preparation of the ground for Hollyhocks is important, and this should be seen to in the autumn. The Hollyhock is a gross feeder and requires a deeply-worked soil with a good dressing of farmyard-manure, and when the ground is trenched up in the autumn the winter weather prepares it for planting in April or early in May. The young Hollyhock plants should have been well inured to the open air before planting them out, and the operation of planting should be performed when the weather is mild and the ground dry. The permanent stakes must also be placed to the plants at the time of planting-out—indeed, it is much better to drive the sticks firmly into the ground before planting, and dig out a hole at the front of the sticks, into which should be placed some prepared soil, such as is used to pot *Pelargonium*, to give the plants a start. The plants must be tied to the stakes as soon as they have grown a little, and it is a good plan to mulch around the roots with a little decayed manure; this keeps the soil moist, preserves a more equable temperature over the roots, and the plants will make a much better growth. As the season advances, if dry weather sets in, water at the roots will be needed, and it will also be desirable to syringe well underneath the leaves to keep off red-spider. The first appearance of the fungus which has been so destructive to Hollyhocks in late years is the signal for an attack upon it; if it is taken in time some good may be done, but when it has spread widely over the entire collection of plants the case is hopeless. It requires a good stout stake to hold a well-grown Hollyhock plant in position, and as the spikes advance in growth they must be securely fastened to prevent their being snapped over by a high wind. A good strong plant will throw out many side-growths, and it is usual to remove these so that all the strength of the plants may be thrown into the centre spike. Upon the side-growths there are also numerous flower buds, but at the base of each there are a few leaves with leaf-growths at their axils; all these may be taken and cut out as Vine-eyes are treated for propagation, and if inserted singly in a small flower-pot, they will soon form plants in a mild heat, if covered with a garden frame. All decaying flowers should be removed from the plants, as they not only have an untidy appearance, but they also cause the seed-pods to rot.

Seedling raising is also interesting. Sow the seeds in May, and the seedlings, if well attended to, will form strong plants for flowering the following season. They may be sown out-of-doors, or, what is better, in a frame over a hot-bed. The seeds are more likely to germinate well in that position, and the seedlings can easily be pricked out into boxes to be transferred to the open borders as soon as they are large enough. They ought to be planted where they are to flower in good time, so that they are well established before the winter. Seedlings are seldom injured by frosts.

HERBACEOUS BORDER.

I HAVE a herbaceous border which has been made five years. The soil is naturally very sandy here. Two years ago I had some clay dug into it, and occasionally I dig in a little manure when putting in fresh plants. I should be so glad if you would kindly advise me what to do with it, and when to have it done? It is a mixed herbaceous border, and needs to be made wider, and I wish to add more herbaceous plants. Would you kindly say which are the best for flowering in July, September, and October?—H. B.

[The only way to improve the soil of the border, as you have already added some clay, is to give a mulch of manure each autumn, to be forked in early in the year. As, however, the border has already been in existence five years, a thorough overhauling with replanting may be advised. We believe it is insufficiently recognised that sandy soil requires more attention in this way than do the more holding or clay soils, the plants in the latter often succeeding for many years without showing signs of deterioration. The early autumn is a good time for replanting such a border, but as you appear to appreciate the autumn flowers, the same work could be

done quite well in February or March. We strongly advise autumn, when bulbs are mingled with the usual hardy things, for at such time all may be planted with safety. But at any time when the work is done, nothing short of a very deep digging and a heavy manuring will be of use, and more clay may be added at the same time. If it were possible, the following is a good plan: Lift and heel in the plants you have for the time being, then dig and heavily manure the border and finally give a surface dressing of clay. Allow this to remain on the surface all the winter, and the frost having well pulverised it, fork it in rather deeply in February and plant the border a little later. This should give good results, and such as may last for years, and as you are adding other plants and widening the border, the opportunity should be embraced. Some of the best things for the months named are: *Platycodon*, any, *Rudbeckia purpurea*, *R. Newmanii*, *Achillea* in variety, *Kniphofias*, herbaceous *Phloxes*, *Montbretias* in variety, *Campanula vesicaria*, *C. lactiflora* in three varieties, *C. Van Houttei*, *Cimicifugas*, any of the Perennial White *Margarites*, *Perennial Pea*, *Echinops*, *Eryngiums* of sorts, *Erigeron speciosus*, *Erodium Manesavi*, *Galetia candicans*, *Gaillardias*, *Galegas*, *Harpalum*, *Helianthus* in variety, *Heleniums*, *Lychnis chalcidonica*, *L. Haageana*, *Lathyruses*, *Aster Amellus* in variety, *A. acris*, *A. Lavigata*, *Anemone japonica* vars., a set of the *Michaelmas Daisies* that should embrace *Coombe Fishacre*, *cordifolius elegans*, *lavis*, *Mrs. Peters*, *Novae-Angliae Melpomene*, *Mrs. F. W. Rayner*, *Wm. Bowman*, *turbinellus*, *N. B. Arcturus*, *N. B. densus*, *N. B. F. W. Burbidge*, etc., *Veronica longifolia subsessilis*, *lino blue*, (*Oenothera macrocarpa*, *Aconitum pyramidale*, *Centaurea ruthenica*, *Scabiosa caucasica* and *alba*, *Statice latifolia*, and *Potentillas* are also among good flowering things, some of which, however, you may possess already. A few groups of *Gladioli* could also be added for the season when you most wish for flowers, while the striking *Physalis Franchetti* is a plant not to be forgotten.]

A GARDENER'S WISH.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—I am an old woman, sixty this month, and cannot remember the time when I did not garden. I was an only child, and therefore a lonely one, but both my father and mother were lovers of flowers; my mother especially so, and I rather think it was her example in the garden that made my father such an ardent disciple. And so I grow up, and my garden has ever been my keenest delight. Much sorrow has come to me, but I find no purer, no better interest than my flowers, and my hope in writing this is that all readers of this paper will teach their children to garden. Its delights are never-ending, and certainly all pertaining to the beautiful is elevating. I think all parents should, wherever possible, give their children little pieces of ground to keep—and keep not as the parents think, but as the spirit moves the child, which teaches the child to use his or her brains, and by encouragement and approbation when deserved they learn tidiness and neatness. How well I can recall my own small plot, my little corner in one of the houses, my small pots filled with my treasures, and the intense pleasure it was to me to care for them. The force of example does much, and when others see how much can be done to beautify one's home, they try to emulate you, and so the example of one good woman in her love of flowers can raise a whole neighbourhood, for I have known of its being done. There is no greater help to the searcher after knowledge than this penny paper, which to me has been a help in difficulties for many a long year, and a weekly treat to look forward to. You cannot think, until you experience it, how much interest you learn to take in other's troubles. A garden is a never-failing source of interest—the watching in spring for the first leaf to come through the frozen earth, and when it comes with all its fresh beauties, that give one hope of summer, with all its wealth of verdure and brilliant colours, autumn, with its varied tints, and even winter, which has its own charms, and we live through many plants, sometimes in the seed-

hope of again seeing spring. And spring, as we have it in our dear Homeland. Where is there a place so sweet on the face of the earth? I have spent springs—what a misnomer!—in India, Ceylon, Australia, Egypt, etc., but where do we find spring so sweet, so lovely, so fresh, as in our own little island? The flowers may be more gorgeous in other lands, but they lack the delicate fragrance of our own humbler-tinted blossoms. Let us all unite in trying to teach the young a love of flowers. AN OLD GARDENER.

NOTES FROM AN ARMAGH GARDEN.

A LONG, severe winter, followed by a late spring, was, I think, by no means an unusual experience in this year's gardening. It is many years since we had a winter here so trying to plants that are just on the borderland of hardiness. A very fine *Dracyna australis* that had survived for many years was completely wrecked, the stem alone remaining; this now stands almost 7 feet high, and I have utilised it to train a golden and silver variegated ivy pillar fashion. Once before, many years ago, it was cut down by frosts, but after a long interval it surprised me by reappearing and making vigorous growth. I have, therefore, not quite abandoned hope of another reappearance. A few feet away a fine plant of a Palm (*Chamærops excelsa*) survived the winter without any protection other than the sheltered position which it occupies near a wall. Among shrubs, etc., Bamboos were a good deal cut up, and have not yet altogether recovered their good looks, but they are now improving. *B. fastuosa* is one of my most recent additions, but I have not yet planted it out. *B. nitida* has made considerable growth and is a very graceful Bamboo. *B. palmata* seems a great rambler; it has encroached on quarters devoted to other purposes in a manner certainly not anticipated, and in some cases not required. However, some of the undesigned combinations which it has effected come as pleasing surprises, and induce one to tolerate the intrusion. *Clematis Pallasi purpurea* is an extremely ornamental herbaceous plant, with numbers of small white flowers which contrast well with the rich dark-tinted foliage. It has formed a fine clump, and has remained in bloom for a considerable time. *Phlox suaveolens variegata* is a very elegant little ornament for the choice position it occupies near the front of a rock garden. The foliage is creamy-white, with some touches of a lovely shade of bright green, the neat little flowers being pure white. Three beautiful little *Thalictrums* are *T. adiantifolium*, *T. adiantifolium glaucum*, and *T. tuberosum*, the foliage of each being very elegant and Fern-like. The *Thalictrum* which I first acquired as *adiantifolium* is a very different and much inferior plant to that which I have recently obtained as the true kind, which bears a very close resemblance to the small-leaved Maiden-hair Ferns. A very uncommon-looking *Thalictrum* is *T. laserpitifolium*, the leaves longer and very different-looking from those of any other Meadow Rue with which I am acquainted. My plant is about 3½ feet high, with pale yellow flowers. At the end of May and beginning of June several beds of seedlings of double and semi-double Welsh Poppies presented a gorgeous blending of colour, comprising yellow, orange, and a still deeper tint almost identical with that of *Geum minimum* in a setting of pretty green foliage. As I grow and flower many hundreds of these plants from seed, I have obtained considerable variation. Numbers of the seedlings have now formed large plants producing quantities of bloom. Some of the deepest coloured and very double kinds have hitherto yielded no seed. Some plants afford a few wretched-looking pods, while others seed with tolerable freedom. Some of the yellow varieties produce large handsome flowers which open well, a few of them with deep orange petals near the centre. Many of the deep, rich, Geum-coloured flowers do not open so fully as I would like, but I have obtained at least one which combines the charm of rich colour with open symmetrical form. I have been very much interested in raising and flowering these new varieties of *Mecanopsis cambrica*. The seedlings often bloom when

bores, and these flowers are charming little miniatures. Many of the seedlings are single, and some of the semi-double flowers are a long way behind the best forms; yet even among these are some pretty varieties well worth growing. Just now there are crowds of seedling plants as yet unbloomed, and there is a delightful element of uncertainty as to what form or colour each opening flower may take, and still the hope that some new break may reward perseverance.

J. McWALTERS.

The Mall, Armagh.

LILIES AND ROSES.

In the height of the summer, when the two rival queens of the garden, the Rose and the Lily, are disputing sovereignty, border and bed, porch and trellis, are bright with countless flowers, beautiful indeed, but falling short of them in loveliness. Lilies and Roses associate charmingly with one another. The Crimson Rambler, whose somewhat crude colouring

pergola and porch. Rosa polyantha, besides its charming type known as R. polyantha simplex, and its larger form grandiflora, has given us the pink Euphrosyne, the nankeen Claire Jaquier, the flesh-pink Psyche, the white Thalia, the pale-yellow Aglaia, the pink Leuchstern, and the deep-coloured Crimson Rambler. From the Ayrshires, or Rosa arvensis race, we have the white Bennet's Seedling, and Dundee Rambler, white shaded pink. The Evergreen or sempervirens section has provided the pink Flora, the white Félicité-Perpetuo, and the pale pink Myrianthes Renoucle. The half Garland Rose and the white Mme. d'Arhlay are hybrid Musks. The glorious Carmine Pillar, glowing crimson, and Longworth Rambler, light crimson, are hybrids, while of Hybrid Teas we have the vigorous Reine Olga de Wurtemberg, bearing great semi-double, light crimson flowers, and making shoots 12 feet and more in length during the season. Teas and Noisettes also furnish us with many strong-growing climbers, such as

many other Lilies are found to flourish, L. auratum, L. speciosum, L. longiflorum, and L. Browni becoming permanently established, and even the lovely flesh-pink L. Krameri doing well and flowering freely, but these are not to be relied on, as are the earlier-named species. The pale yellow L. Szovitzianum will generally, though not always, succeed, and in deep soil the noble Giant Lily of the Himalayas (L. giganteum) forms a splendid picture.

S. W. F.

NOTES FROM A ROCK GARDEN.

TO THE EDITOR OF "GARDENING ILLUSTRATED."

SIR,—Owing to the wet summer, one has been able to plant out seedlings and early-struck cuttings during August, giving them a chance to get well established before the winter. Few people seem to grow rock plants from seed. Not only is it more interesting than buying the plants, as something new may appear, but so much exchange may be done

Lilies and Roses in a Hampshire garden. From a photograph by F. Mason Good.

renders it objectionable where other bright tints are present, is handsome when seen with only a complement of green, as where its blossoms drape an archway having a background of full-foliaged trees, while a trellis covered with this Rose in full flower, fronted by a wide row of Madonna Lilies, furnishes a striking and pleasing contrast. Of the summer-blooming, so-called "garden Roses," there are many, notably the old Cabbage Rose, Maiden's Blush, the pretty little De Meaux, the striped York and Lancaster, the white Provence, and others which all form good bushes, as do the Austrian Briers, single and double, the Persian Yellow, and the Penzance Briers. In climbing Roses suitable for covering porches, verandahs, trellises, or even for clambering to the top of small trees, we have a wide selection. Our Dog Roses of the hedgerows testify to the beauty expressed by the rambling Brier, and other wild species will succeed equally well with us, but it is chiefly to the varieties raised from these wildlings that we owe the soft colours with which the climbing Roses mantle

Mme. Alfred Carriere, cream-white, Mme. Bérard, salmon, and Waltham Climber, light crimson, in the first section, and such varieties as the white Aimée Vibert, the copper-yellow Réve d'Or, and the apricot W. A. Richardson in the second, while in the warmer localities the white and the yellow Banksian Roses may also be grown.

In Lilies, although the peerless Madonna Lily holds the first place, there are many others that are of easy culture in the border, such as the common Orange Lily (L. croceum), the many named varieties of the comparatively dwarf-growing L. Thunbergianum or elegans, and the L. umbellatum section, ranging in colour from lemon-yellow to crimson, the buff L. excolsum or testaceum—a hybrid between L. candidum and L. chalcodonicum, L. Martagon, and its white form, the scarlet Turk's cap (L. chalcodonicum), the Tiger Lilies, of which the best are L. tigrinum splendens and L. t. Fortunei. L. Henryi, called the yellow speciosum, is also a vigorous Lily, but at present rather expensive. In some gardens

with surplus seedlings, however small the rock garden is. This year I have grown from seed Dianthus caesiis (the Cheddar Pink), a delightful plant for crevices, D. deltoides, D. superbus, Linum flavum (the yellow Flax) for a hot, sunny corner, Linum alpinum (the dwarf blue, trailing one), and Linaria alpina, in heavy soils an annual, but in light dry soil a perennial. I have a good batch of the new Polemonium confertum melitum, one of the loveliest of rock plants, with its delicate creamy hanging flowers, planted in a well sheltered nook with a south-west aspect. Seedling alpine Auriculas, when large enough to handle, are pricked out on a north border and put on the rockery in the autumn. Primula obconica is now flowering again. The plants are protected in the winter with a mulch of leaf-mould. This is the time to take cuttings of alpine Phloxes—Vivid and Nelsoni are difficult to strike, their stems being so hard—Dianthus Napoleon III., D. Marie Farr, Lithospermum prostratum, and the best coloured of the Helianthemums. These likewise grow freely from seed. The

encrusted Saxifrage strike easily and are ready to plant out in the late autumn, though some of the choicer ones, such as *laetoscana*, *Rocheliana*, *valdensis*, and *Engleri*, might be wintered in a cold frame. The young rosettes of *Androsace sarmentosa* are now ready to be pegged down, and have a top-dressing of leaf-mould, sand, and fine grit. In some districts this plant is taken up and replanted every other year. Here, in Yorkshire, it is liable to damp off after such treatment. *Daphne Cneorum* is better layered now into peat and sand. The new African annual, *Arctotis grandis*, is useful for a hot, fully exposed part, and it produces its silvery-blue Daisy-like flowers till the frost comes. The Lavender Cotton (*Santolina alpina*) on the high parts of the rock garden is now a mass of golden flowers, falling over the rocks. Its grey foliage shows off to advantage in winter. A good companion for this is *Phlomis fruticosa* (Jerusalem Sage), also grey foliaged, with a yellow flower, both blooming about the same time. The *Wichuriana* Rose is now showing bud, and in another few days will be covered with its fragrant white, single flowers; the type blooms later than its hybrids *Jersey Beauty* and *Gardenis*. *Gaura Lindheimeri* has white, starry flowers, not unlike those of a Willow-herb in shape. This, with *Delphinium nudicaule*—sown in March—now makes an attractive group. *Gentiana septemfida* is now out, this wet summer having suited it. I never saw its flowers a better blue. It always comes as a surprise, following when all the smaller *Gentians* are over. *Primula capitata*, with its powdered blue-purple flowers, is well worth growing. The seed ought to be saved, as it often dies out after blooming well. This summer the *Oenothera missouriensis* and *fruticosa* have been very fine, their flowers remaining perfect all through the day. *O. marginata*, requiring more sun, has not done so well. I have it planted in very sandy light soil in a sheltered corner, where it spreads rapidly, and last summer did well. In Devonshire, this June, I came across a most striking *Mesembryanthemum* growing like a weed all over the stony sides of the cliffs; it had large sulphur-coloured flowers, quite 3 inches across. It strikes easily, and would be an excellent plant for hot, dry banks where little else would grow. It is evergreen. A severe winter in the north might kill it, but it is well worth trying, as a few cuttings could always be wintered in a frame, in case the old plants suffered.

Drigton Grove, York. E. M. W.

NOTES AND REPLIES.

Iris Gates in Devon.—There is a small clerical error in the note on "Iris Gates in Devon." It should be, "the open flower 13 inches from top, etc."—A. BAYLOR.

The disease in the Madonna Lily.—I am sending a photo of Madonna Lilies, which were a great success this year. Originally they were in herbaceous borders, but owing to their being attacked by this disease I had to move them two years ago, when they were planted in their present position in the kitchen garden, after having been well sulphured and dried in a greenhouse for about a fortnight. This year they bloomed well, and with the exception of about six or eight were entirely free from disease. I am giving these notes, as I so often see questions and articles on the Lily disease, and thought my experience might be interesting. I saw the treatment recommended in your paper first. I intend trying some of the best bulbs in the borders again now that they seem to be all right.—Mrs. E. D. HOUNES, *Daleholme, Craighead, Co. Down.*

[The photograph showed a very handsome group of this in full flower, and apparently quite healthy, the foliage and flowers being all one could wish.]

Marguerite Carnations.—Miss Spurrway sends us from her garden at Mount Wear, Exeter, a beautiful gathering of these from plants raised last year. The colours are rich and vary from scarlet to pure white, the flowers double and beautifully fringed. The blossoms of these, though not large, are graceful in vases for table decoration. Any sturdy plants that have not yet flowered may be lifted, potted, and kept in a cold greenhouse, and will give abundance of blooms for months. Such plants are benefited by a watering of weak liquid-manure when coming into bloom. These will be found very useful during the autumn for conservatory decoration.

Lawn decoration.—Have a Fir-tree that is about 8 inches in diameter sawn off quite flat at the base. Remove all branches up the stem for 12 feet, and leave all the branches that are growing at that height, and cut the remainder

of the tree off. Then sink the tree 2 feet into a lawn and plant a Honeysuckle at the base and train it up the Fir-tree, cutting off all side shoots. On its reaching the branches train it round and round the branches, commencing in the centre, until the Honeysuckle has gone all round to the end of the branches. Then let it grow just as it likes. It is a very rapid grower, and in two or three years you will have a tall, beautiful, and graceful tree, with branches hanging down and swaying in the wind, covered with lovely flowers, and when they are over with bright red berries. Roses and other climbers can be trained in the same way, but require better attention in the way of a border, mulching, removal of weeds, dead branches, etc., but Honeysuckle is very hardy, and thrives well planted almost anywhere. It is easily struck, and if cuttings are now stuck into the ground in any damp situation and left till next spring, they will be found to have good clusters of roots, and the plants will flower next June and make a rapid growth if planted in a sunny place.—Mrs. E. MAY.

Seeding Carnations.—I have a bed of Carnations grown from seed last year, 15 feet by 6 feet, a lovely sight just now, and giving any quantity of cut flowers. May I trouble you to kindly tell me in an early number of your excellent paper, *GARDENING ILLUSTRATED*, from which I have derived great pleasure and instruction, how best to treat these for next year? When blooming is over should they be cut down, and will the roots throw up new stalks to bloom next year? Can some of the roots be transferred later on to another bed, as they are, I think, too thickly planted, or must I take layers or cuttings and do away with the old roots? If so, kindly say the best way to take and treat layers and cuttings? These and any other directions will greatly oblige.—KINGSTON.

[You should at once have the flowerless shoots on your best Carnations layered. That is best done by someone who understands it. It is getting late for layering, therefore lose no time. When, at the end of November, the layers are well rooted, they can be lifted and planted in fresh ground. If there are still some shoots left unlayered, then you can, after the rooted ones have been removed, either allow the old plants to remain, putting fresh soil about them, or lift them carefully with a spade, having good balls of soil about the roots, and replant them elsewhere. It is a good plan to have a hole in the new ground made ready to put the newly-lifted plants into without greatly disturbing it. All such plants should grow well next year. All present flowerless shoots now will carry bloom next year. If you put in some shoots as cuttings, set them in sandy soil under a handlight at once. These should be about 4 inches long, and be dibbled in 2 inches apart—half their depth. It will pay you best to hire an expert to do the layering. Cut away all over-blown stems now.]

Triteleia laxa and T. uniflora.—In the late spring I saw a fine patch of *T. laxa* blooming abundantly in an open border near Yeovil. The spikes were 12 inches long, and made a fine show with their loose rich Tyrian purple flowers at the edge of the border. Adjoining were large patches of various kinds of Pinks and other hardy border plants, with groups of annuals. Especially noticeable was *Phacelia*, with its uncommon blue flowers. I was told this *Triteleia* bloomed in this way every year and received no extra attention. I have it growing at the edge of a shrub border, where it blooms each season. Good as this is, *T. uniflora* is equally so. This is fine for growing in patches in the rock garden, or in groups in sheltered beds or borders. I have a group of it at the foot of a Tea Rose under a south wall. Here in early spring I always get abundance of flowers, and it receives no protection.

Planting out old pot Mignonette.—In many gardens a batch of this is grown for winter and spring blooming, and when no longer of service for this purpose it is generally thrown away. This is a mistake, seeing it will bloom early and over a long time if planted out in a favourable place. For years as soon as over (early in May) I plant all of it out, either in kitchen garden border to cut from early, or amongst Roses in the grounds, where it continues to bloom till the autumn frost destroys it. For cutting it comes in long before that sown in the open, for immediately it begins to grow good spikes may be cut. I simply turn it out of the pots, remove the crocks and plant intact, then it quickly takes to the soil.—J. CROOK.

GARDEN PESTS AND FRIENDS.

NOTES AND REPLIES.

The Marguerite Daisy-fly (*Phytomyza almidis*).—My Chrysanthemums are greatly infested with a small maggot which is between the leaves and disfigures them greatly. I suppose it is the leaf-minning maggot. The plants are in a sunny but sheltered position in 8-inch pots, and good soil. I shall be glad of a remedy.—CONSTANT READER.

[Your plants have no doubt been attacked, as you imagine, by the grubs of the Marguerite Daisy-fly, which burrow in the leaves of Chrysanthemums, Cinerarias, and other composite plants. The best way of destroying this insect is to cut off the infested leaves and burn them, or, if the attack has just commenced, to pinch the leaf at the part where the grubs are. Syringing with an insecticide is of little use, as it would not reach the grubs, but it would possibly prevent the flies laying their eggs on the leaves if it could be applied at the proper time.]

Caterpillars on Rose-bushes (*Truquay*).—Your Rose-bushes are attacked by the grubs of one of the Saw-flies (*Hylotoma rosarum*). The best way to destroy them is to go carefully over the plants and pick them off. If they are very numerous, and many plants are infested, it would be worth while to spray them with paraffin emulsion. When full grown they will bury themselves in the soil 2 inches below the surface, where they become chrysalides. In the course of a week you might remove the surface soil 2 inches in depth and burn or bury it. You would then destroy all the chrysalides, or, if it were not convenient to do so, ground to the depth of 4 inches and turned up early in the winter, so as to expose the chrysalides to the weather and the birds.—G. S. S.

Insect in house (*Acon*).—When your letter reached me there was only one kind of insect in it, although there were several specimens. The insect is commonly known by the name of "silver fish," "silver wick," "sugar louse," or "bristle tail." It generally feeds upon starchy substances, and, in many cases, has injured books by feeding on the paste used in binding them. It is fond of getting behind wall papers and eating the paste. Curtains and articles of dress which have been starched have at times been injured by it. It is clear, however, that it will occasionally feed on animal substances, such as wool or felt. Probably some of the carbolic disinfecting powders would have the same effect as Keating's, but the latter, if sprinkled about for a week or ten days regularly, would be most likely to exterminate them. I forgot to say that the scientific name is *Leptisma saccharinum*.

Wood Leopard-moth (*Zeuzera aesculi*).—I am troubled with a pest in my Apple-tree, the nature of which is quite unknown to me. It attacks the wood of the tree, in the trunk of which it holes appears, and in this each morning are a number of little egg-shaped pellets of sawdust. The hole then gradually increases in size, and it also extends out of sight right into the heart of the tree upwards. One tree, a Cox's Orange Pippin, is much damaged, the hole being large enough to contain one's finger. I am unable to discover the cause, as nothing living can be traced, even under a microscope, but I send herewith a number of the pellets for your examination, and you can inform me what is the cause of the trouble and the remedy I shall be extremely obliged.—GUY.

[Your Apple-tree is bored by the caterpillar of the Wood Leopard-moth (*Zeuzera aesculi*), and by no means uncommon insect. The presence of one of these caterpillars in a branch or stem may be detected by finding small sawdust-like particles sticking to the tree where a little moisture is oozing from the bark; on closer examination a small hole will be found from which these particles (which are composed of small pieces of the wood gnawed off by the caterpillar and its droppings) are exuding. The easiest way of killing the inmate is to pass a sharp-pointed wire as far as possible into the hole, which will usually be found to proceed upwards, so as to stab the caterpillar. It can usually be seen, from the appearance of the wire, whether the insect has been reached or not; if by any turn in the tunnel it has not, the entrance to the tunnel should be slightly enlarged, and some cotton-wool or tow soaked in tar or paraffin-oil should be pushed in as far as possible to stifle the caterpillar, and the mouth of the hole should then be closed tightly with a plug of clay, so as to keep the smell in.

If it is possible to cut off the branch without injury to the tree, you can then, by splitting it open and killing the insect, make sure that it is destroyed. The caterpillar lives for three years before it attains its full growth and becomes a chrysalis, which it does near the mouth of its burrow. The moth is a fine and very elegant insect. The females are considerably larger than the males, and are 1½ inches in length, and measure 2¼ inches across the wings, which are white and almost transparent, with yellowish-brown veins, between which are rows of roundish bluish-black spots. The body is white, with black markings. They may be found in July or August.]

FERNS.

THE ROYAL FERN (OSMUNDA REGALIS).

This, our native Royal Fern (*O. regalis*), is found in many bogs and marshy woods, and is well worth cultivating, as it is the largest and most striking of our native Ferns (sometimes attaining a height of 8 feet). It should be

12 inches high, but have stopped growing. I may add that I have standard Tea Roses between the poles and they have done well. Can you explain the cause of their dying? They had grown about 15 feet to 16 feet at the time.—A. P. DAVISON, *Banbury*.

VEGETABLES.

SELECTING SITES FOR WINTER VEGETABLES.

MUCH may be lost or gained in winter by the choice of site for, at least, some kinds of vegetables. It is common knowledge that vegetation in the open market fields is stronger than in the garden hemmed in by walls, and further hindered by fruit-trees, which usually share the same ground. The hardy vegetables may, and often do, take care of themselves under any circumstances—others less robust succumbing to adverse weather even of short duration. There is nothing to which the latter remark applies more forcibly than Broccoli. None of these are too hardy, given unsuitable ground and shelter, and the early

and may be planted anywhere. Turoips, too, are similar. It is hopeless expecting large roots to endure frost, so the alternative is to sow at different times until the middle of August. Spinach will grow in open or on sheltered borders, but it suffers anywhere if frost follows mild weather. With Endive it is possible to have plants that will live outdoors through a severe winter; it is equally possible for two or three severe frosts to destroy whole plantings. I have had this happen when protected somewhat with light coverings of leaves. Any vegetables when in an advanced state are more sensitive of weather changes than those of less age and size. Winter Endive is not safe left in the open, frame protection must be given if a daily supply is expected. Lettuces, always so valuable, if to be had in winter should be planted on different sites. In the winter and early months of the year, the foot of a warm sunny wall is the only suitable position. Of these, too, it is impossible to make too many sowings in July and August. The plantings may be small or large, according to the demands to be met.

It is well, therefore, in planting for winter and spring to consider the variety and the time of its maturity, remembering that the latest sorts and smallest plants have the greatest resisting power against cold.

W. S., *Wills*.

GLOBE ARTICHOKE.

I HAVE about half-a-dozen plants of Globe Artichokes about four years old. Wishing to increase the plantation of these to some fifteen plants, will you please give me some cultural directions? Can I divide the plants I have, which have attained to considerable size and bear well? What time to plant, preparation of ground, etc.? Soil sandy loam, over shingle.—E. P. S.

[It is difficult to account for this vegetable not being more popular, for it is truly, when properly cooked, most wholesome. With the majority of people, however, in this country it is looked upon as worthless. Can this be because they do not understand its cultivation, or on account of not knowing how to cook it? There is one drawback to its becoming more popular, which might be easily overcome by a little forethought, and that is, the liability to be injured in severe winters, particularly where the ground is heavy. If a few ashes be put round the roots on the approach of winter, this will usually enable them to withstand the frost. We too often see the old stools growing in the same place year after year until they become exhausted, instead of making a fresh plantation each spring. It is, however, not advisable to take up the whole of the plot every year, as plants that are allowed to stand undisturbed for two years usually send up their flower-stems earlier than the newly-planted ones, therefore if only half the plot is taken up the season of their usefulness may be prolonged. Much, too, may be done in the selection of suckers, as those that produce the largest and most fleshy heads spring from low down on the old stools where the roots are soft, not from the base of the old flower-stems. These latter, though stronger at the time of planting, seldom grow so vigorously as those produced lower down on the roots. After a fairly mild winter these suckers will be ready to take off the old stools towards the latter part of March, but after a severe one it will be the middle of April before they are forward enough to be separated from the parent plants.

PLANTING.—The ground intended for Artichokes should be liberally manured and deeply dug before planting. Some prefer setting the suckers singly in rows 4 feet apart, allowing 3 feet between the plants in the row, but if they are planted 4 feet apart each way and three suckers put out at each station, better results are obtained the first year. The suckers are planted diagonally about a foot apart, so as to form a clump. Should the weather be dry, it will be necessary to water frequently, but only sufficient should be given to keep the soil moist round the plants. As they are only allowed to stand two years there will be no overcrowding, particularly if all but three of the best suckers are removed the following spring. As the Artichoke is a gross feeder, liberal applications of manure-water must be given at the time the plants are throwing up their flower-stems, and these must be con-

The Royal Fern (*Osmunda regalis*) at Mount Usher.

planted in moist peaty soil, and the most suitable spots are half-shady places on the banks of streams (as in the illustration) or of pieces of water. It may also be planted in the water. When exposed to the full sun it does well, with its roots in a constantly moist, porous, moss-covered soil, if sheltered from strong winds. In shady positions and in deep bog soil it attains a great size.

Clematises failing.—I read a most interesting article on growing Clematis in a recent issue, and as I have been very unlucky with mine, I shall be much interested to know why I failed. Two Jackmani which were planted two years ago on two poles of my pergola, thrived well last year, and this year had any quantity of buds on them, when suddenly they both died right down to the ground. There was no frost and nothing to account for it. One died June 7th and one June 12th. They were on two poles next to each other. The soil is rich, drainage perfect, and they had liquid-manure at intervals in May, and the soil was moist. I cut them right down to the ground, and in a week they both threw up shoots agsin, and are now about

winter ones are particularly uncertain. It is impossible for those which mature in December, January, or February to make headway, if, at the time, there is severe frost, and should the flower be in an advanced state, and overtaken with a sudden fall in temperature, accompanied by night frosts, it almost invariably succumbs if no suitable shelter is provided. I now resolve that whatever the coming winter's prospects may be—and no one can foresee weather events—to plant so as to expect Broccoli at all seasons. The more delicate or mid-winter sorts are, as far as possible, planted where they get some shelter from frost in the morning. It is this which inflicts so much injury on frosted vegetation. A west is better than an east or south aspect. Late sowings of Autumn Giant Cauliflower and Self-Protecting Broccoli, if given this shelter, may continue a supply of small, clean heads almost, or quite, to Christmas, Winter White, a very useful Broccoli, following, and continuing for some time. Then would come Backhouse's, Penzance, Snow's, and Spring White. Savoys are more or less hardy, keeping up a succession, if regulated by sowing and planting. Late-sown ones stand cold weather the best,

tinued, should the weather be dry, until the heads are cut. As a spring dressing, kainit, salt, seaweed, and such-like manures are beneficial. When raised from seed many of the plants are worthless, as the heads are not at all fleshy; some of them have long spines, being little better than Cardoons. It is, therefore, necessary to procure suckers from a reliable source. These, if planted in April and well looked after, will give a supply of nice heads towards the end of the summer. The season may be prolonged by taking off suckers in the autumn, and after potting standing them in a cold-frame where protection can be afforded in severe weather. These plants if set out early in April will usually throw up their flower-stems a fortnight in advance of those that have remained out through the winter.]

NOTES AND REPLIES.

Salsafy and Scorzenera running to seed.—I should like to know if it is better for the roots of Salsafy and Scorzenera if they are prevented from flowering?—M. S.

(The roots of Salsafy and Scorzenera will increase in size without becoming less tender or less fit for use, even though the plants may have produced some flowering stems in the course of the summer.)

Winter Spinach.—This, no doubt, is one of the very best green vegetables that can be eaten, but many think it requires skill to cook and prepare it for the table. It requires to be put into boiling water that has a salt spoon full of carbonate of soda to every gallon of water before the Spinach is put in. A second lot of boiling water, or rather, two saucepans, are necessary for this vegetable, this taking away the bitterness to a great extent. Boil for about fifteen minutes, then put through a fine sieve. The principal sowing should be made not later than the 20th of August in rows 15 inches to 18 inches asunder, and thinned out to 6 inches apart when fit to handle. Ground recently cleared of Potatoes or Peas will come in well for this crop, if a fair dressing of soot and wood-ashes combined be spread evenly over and the ground forked over and levelled with the rake in the usual manner. When the soil is found to be extra dry, it is well to saturate the drills—which should be 1 inch deep—before sowing the seeds. I find the Round Summer Spinach withstand the winter equally as well as the Prickly or Winter variety, but it is wisest to sow a piece of each, as the former may not succeed everywhere during winter. Perpetual or Spinach Beet is often sown as a substitute in case the ordinary kinds fail or become exhausted. I have used Sorrel in extreme cases.—J. M. B.

Protecting Globe Artichokes.—Last year I made a new bed in sandy loam which has turned out a disappointment, and my gardener thinks owing to frost spoiling the crowns, though these were well covered with litter. I suggest ashes for covering, then straw, or would a light roof be better? They are not too crowded, but I find a disposition to make small suckers, and have tried to thin them out in spring to one or two crowns.—Snow-droo.

[With newly-planted Artichokes it is not a good plan to use straw litter as a protection in winter. This lies too damp about the crowns, and also encourages slugs to eat away the young leaves and tender crowns. Nothing we have used serves the purpose so well as ashes. These being porous allow rain to pass through, while at the same time they lie closely around the crowns of the plant protecting the most vital parts. In some soils Globe Artichokes give trouble in winter by dying out, but in sandy loam, with a covering about the crowns in late autumn, there should be no difficulty. We do not attempt to reduce the growths to one or two for the reason that the crop in summer would be too limited. Encourage sucker growth rather than restrain it until the plants are strong and bushy, when they may in early spring be divided, at least, some portion of them, and replanted on fresh ground. If you have decayed litter about the plants now remove it, and before wintry weather sets in, place a covering of ashes some 2 inches or so in thickness. A little soot sprinkled around them previously would help to dispel slugs, which do damage sometimes. Some decayed manure may be forked into the surrounding soil in spring after the ashes are removed. Liquid-manure given at any time during spring and summer would stimulate vigorous growth.]

GARDEN WORK.

Conservatory.—Tuberous Begonias, Fuchsias, and other plants which have ceased to be effective, should be placed outside to complete ripening. Better arrange the plants a little thinner than keep anything in the show house which has passed the best period of flowering. There may be for a week or two a time of scarcity as regards flowering plants. Hydrangeas, if not already done, should be cut down, and the best of the cuttings inserted in sandy soil, and plunging the cutting pots in an old Cucumber or Melon bed where there is still a little warmth, where roots will soon form. Scarborough Lilies (Vallotas) are now showing flower-spikes, and where a good batch is grown they will make very bright groups during the autumn. Montbretias and Hyacinthus candicans do very well in pots, and will be useful in the conservatory now for a change till other things come on. Camellias and specimen Heaths should soon be placed under cover. Pelargoniums that were cut down have now broken into growth, and should be repotted in clean pots of the same size, or in some instances, smaller pots may be used. Be careful about the drainage as this is important. Zonal Geraniums intended for winter flowering may now be permitted to bloom if early flowers are desired, and they are always useful. Make a further sowing of Mignonette. Remove most of the shading from Cyclamen frames as the plants draw if much shaded, and the earliest plants will soon be showing blossoms. Ventilators very freely, and in bright weather sprinkle every afternoon. Scarlet Salvia, if grown in pots, should now have the final shift. If planted out, cut round with the spade so that they can be lifted by-and-by with balls of suitable size to fill the pots intended for them. They must not be left out too long, as frost will injure them. We must always be on the look out for frost after the middle of September. Chrysanthemums, even those intended merely for decoration, should be helped with liquid-manure now. In the matter of keeping, something may be done to make the house attractive. Decayed flowers should be promptly removed without waiting for a clearing-up day, though rearrangements should be made as often as time will permit. Insects are not generally so troublesome at this season, though both red-spider and thrips are sometimes present if there has been any want of cleanliness or moisture.

Stove.—Regular fires will be necessary now, though, as plants are being brought back from cooler houses and pits, the temperature should not be excessive from fire-heat. Shading should scarcely be necessary now. Though up to the present there has been very little summer weather, it is possible September may bring us the Indian summer we have sometimes in this month, and the conditions must be made suitable for the plants. Achimenes and Gloxinias which have completed flowering may be kept cool and gradually dried off, and afterwards laid on their sides under the stage to rest. Full light, with its accompanying sunshine, will put colour into Crotons, Dracenas, and other fine-foliaged plants. Caladiums will not need so much water, as for the most part their work is done, though the beautiful little variety *C. argyrifolius* will last in condition some time, and, if well done, will be useful for table decoration. Among the newer forms of Caladiums, Crystal, Mrs. Harry Veitch, Queen of the Isles, Silver Cloud, Sir Henry Irving, and Triomphe de Comte are distinct and good. Under favourable conditions Allamandas are still blooming freely, but, where flowering is over, less water will be required, and the plants gradually allowed to go to rest. Most of the watering should be done in the morning now, and, as the days shorten, less moisture should be used in the atmosphere; but all changes must be gradual, and will in some respects keep pace with the fires.

Cucumbers in frames.—Less air will be required, as the sun's warmth will be wanted to keep up the temperature and encourage growth. No shade should be used, and the water given should have the chill taken off, either by standing in the sun or mixing with hot water from the boilers. Cover the frames

at night with mats to keep in the sun's warmth accumulated during the day. By giving proper attention, the plants may be kept bearing some time yet.

Orchard-house.—There will be a few late Peaches and Plums left yet, if late kinds are grown; but for the most part the trees will be outside ripening wood, but must not be permitted to suffer from want of water. This is the time when mischief is done to the buds if the roots are permitted to get too dry. Any trees which require larger pots should be shifted this month, and those trees in large pots may be carried on by top-dressings of good loam and a little old manure and bone meal, with a dash of soot.

Tomatoes under glass.—These are ripening fast now, even in cool-houses. The medium way is best in giving stimulants. Plants very highly fed may burst or crack their fruit, and then the crop is less valuable. Give all the air possible during the day, and leave a part of the ventilators open all night. As a rule, Tomato-houses are required by the end of the month for storing plants in pots, and a few leaves may be taken from the Tomato-plants to hasten the ripening, and afterwards less water will suffice. Those who want Tomatoes in winter may adopt either of two courses. They may leave one house where the plants are healthy and tie in the young shoots that will break up the stem after the fruits are gathered; these, by stopping when a truss of flowers has been secured, will do well and produce good crops with a top-dressing of good soil. The other course is to have a stock of young plants now, and grow in pots near the glass in a light, warm house. The first course will be found the best, as, unless the fruits are getting forward by the end of October, they will not be of much use. Neither systems will produce a paying crop as the prices run in this country now. The market grower contents himself by sowing early in the new year, and runs his young plants quietly till the days lengthen. Tomatoes require plenty of light to do well.

Window gardening.—The Campanulas are still effective, and there are a few Begonias and Zonal Geraniums. But the principal work just now is putting in cuttings for spring. Myrtles will root now, as will also pretty well every plant of which cuttings can be had. Early-flowering bulbs, such as Roman Hyacinths, Freesias, Narcissi, Snowdrops, and Crocuses, may be potted now and plunged outside in coal-ashes to make roots.

Outdoor garden.—Gather seeds of anything good and choicer before the pods burst, and place in saucers or other vessels in an airy room. Among the seeds which should be looked after are good strains of Hollyhocks, Pentstemons, Gaillardias, Coreopsis grandiflora, Paeonies, Dictamnus Fraxinella, Scabiosa caucasica. The last is one of the most beautiful things we have now for cutting, and may be easily raised from seeds in spring. Sow in a box in frame and transplant when large enough. It is necessary to raise a few plants every season, as old plants often die during winter, especially in wet, cold seasons. This the growth of Cactus and other Dahlias if fine blooms are wanted. The staking and tying also must have attention, as the plants are heavy, and offer no resistance to gales of wind unless well supported. Beds for choice Pinks should be made ready, and the plants set out in good time. Edging and border plants may be pulled to pieces and replanted firmly, burying the stems up to the foliage, and they will soon form roots if kept moist. Groups of Tritomas coming into flower will be improved by a soaking or two of liquid-manure. Polygonum cuspidatum is an effective autumn plant in a good-sized group in front of a shrubbery or at the back of a border. The propagation of a stock of tender and other plants should be carried on till enough has been secured. Madonua Lilies should be planted in a well-drained site and not disturbed again.

Fruit garden.—Apples are, in many gardens, a scarce crop. Trees planted about eight or ten years are, in many instances, doing well, showing how necessary it is to keep constantly clearing away and replanting. Grafting is also advantageous where the kinds are inferior and not prolific. This is the

time to take stock of our positions and select sites for young trees. There are several Apples which scarcely anyone can do wrong in planting. Those I have marked for increasing our stock of are Bismarck, Newton Wonder, Lane's Prince Albert, and Cox's Orange Pippin. The last requires a deep, warm soil. This we can give. The Jargonelle Pear does well as a standard in many places, and bears more freely than on a wall. On a wall, after being planted a few years it makes too much growth, and one does not care to be always hacking the roots off, but as a standard, with permission to develop, the growth is soon kept in check by the crop of fruit. All young wood required for extension on wall trees and espaliers should be laid in. Growth now has pretty well ceased for this season, and all strong shoots should be cut back to let every ray of sunshine reach the trees.

Vegetable garden.—There is some disease among the Potatoes in some districts, though I have not seen much of it here, and our own crops are entirely free at present. Fine water now will save the crop, and the Corn harvest also needs it. One is apt to wonder sometimes where all the weeds come from. At the present moment, after the damp weather following a dry time, even land where scarcely a weed is permitted to seed is coming full of small annual weeds. The seeds of many weeds are carried about by the wind, and it is not impossible for the seeds of the weeds to come in the showers of rain. The industrious man has to bear a part of the burden which should be placed on the back of the idle and careless, especially in this matter of weed killing. The hoe on a fine day will soon clear off the small weeds now coming up, and benefit the crops at the same time. Turnips, Spinach, and other crops just up should be frequently gone over with the hoe, and all the surface between the rows moved. Take up all early Potatoes. If the seed is saved at home, carefully select the sets and place them under cover somewhere. There is much in the selection of the seeds of anything. If the sets come from a very prolific root, we may reasonably expect a good crop from them next season. Vegetables, like man, are either moving upwards or downwards; there is no standing still. E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 7th.—Cuttings are still being taken of many things required for next year's furnishing of the garden. In addition, before frost some of the best of the old Geraniums will be lifted and kept for spring propagation. Alternantheras, Coleuses, and Iresines are still used to give colour among sub-tropicals, and, of course, cuttings are being rooted, and will be kept on shelves in a warm house during winter to produce cuttings in spring, as spring-struck plants are best.

September 8th.—Early Potatoes are being lifted, and whosoever a more prolific root than usual is found the tubers of a proper size are placed on one side for seed. A little heat is used over in stove, also for Melons and Cucumbers. Poinsettias have been taken from cold pits and placed in a low warm house. Cactuses which were placed outside in the sunshine have been moved indoors, and the water supply will be reduced. Scarborough Lilies are throwing up flower-spikes and have been taken indoors.

September 9th.—Specimen Azaleas and other hard-wooded plants are being housed, but the lights will be left open night and day, so that the change may be as gradual as possible. Groups of the Chimney Campanula (C. pyramidalis) are very attractive in the conservatory now, so distinct from anything else in growth and colour. Palms that were planged out in summer about the grounds are being taken in, as the cold night and wind gales may do damage to the foliage. Planted out more lettuce and Endive.

September 10th.—Finished planting Strawberries. The plants were started in pots, and are strong enough under favourable conditions to bear a crop next year. They are chiefly Royal Sovereign, Leader, and Latest of All, with a few Elton Pine. Beds intended to

remain to produce another crop are being cleared of runners, and later will be forked between the rows and mulched with manure. Commenced some alterations in shrubberies with the view to introducing a few groups of better things. The ground will be trenched and prepared for planting at once.

September 11th.—Thinned the beds of seedling Cabbages, pricking out a part and leaving others to grow till the ground is ready. The main crop of spring-sown Onions has been harvested in fairly good condition, and the ground will be prepared for Cabbages. Celery is being earthed up in fine weather as required, the soil being well broken up and pressed firmly round the plants, care being taken that none enters the bearte of the plants. Earth is drawn up to Leeks.

September 12th.—Most of the buds of Japanese Chrysanthemums have been secured, and the incurved are now being taken. Up to the present we have seen no rust, but preventives have been used. Early-flowering kinds in pots have been placed under cover, and will be moved to the conservatory as soon as the flowers begin to expand. Early kinds of Apples, Pears, and Plums are gathered in good time before they fall. Late Peaches on walls have been freely exposed by clearing away a few leaves.

POULTRY.

Chickens ailing (T. Yeo.)—Your chickens appear to be suffering from diarrhoea, which is often brought on through exposure to cold and damp, or from being fed upon unwholesome food. You do not furnish any particulars as to what food and management your chickens receive. You should move the coop to a fresh place once a day at least, as foul, tainted ground is as likely as anything to cause trouble. The best food for chickens after their first meal or two of egg and bread crumbs is a crumbly paste made of two parts of coarse Oatmeal to one part of Barley meal, mixed with water. When a few days old they may have grits, crushed Wheat, or bruised Oats in addition to the meal, and also a small piece of cooked meat, rather underdone, and mixed fine, may be given daily until they are about three weeks old. Bread sopped in water, although often given to young chickens, is about the worst food they can have, and causes diarrhoea. Give your chickens their meal in a warm state, also boiled rice, with a little powdered chalk and Cayenne Pepper, till the looseness is checked. Cover the coop at night with thick canvas or sacking, providing ventilation without drought. Castor oil is the best medicine for this complaint, and can do no harm.—S. S. G.

BIRDS.

Treatment of Goldfinches (A. F.)—With good treatment these birds will live for many years in a state of captivity, being generally free from most of the diseases to which other cage birds are subject. They are, from their beauty of plumage, gracefulness, and general docility, very much valued as feathered pets. They will breed freely with Canaries, and sometimes among themselves, where they have the range of an outdoor aviary. The most beautiful male birds are those bred from the Goldfinch and Canary. Caged Goldfinches may be allowed a great variety of food, and Canary-seed, Rape, Hemp, Flax, Millet, Muw-seed, and Groats will all be relished by them. When Thistles are ripening it is good policy to secure a supply of heads for use during the winter. For green food, Groundsel, Chickweed, Dandelion, and Lettuce may be given. A large cage should be provided for these birds, as they are naturally lively and require much exercise. The allowance of Hemp should be somewhat limited, as it has a tendency to darken the plumage. It is somewhat difficult to distinguish between the sexes, but the hen is not so brilliantly-coloured as the cock, and is somewhat smaller. The variety known to fanciers as the Chevril Goldfinch resembles the rest of its race, with the exception that the white streak extends from the base of the lower mandible down to the breast; such birds are highly valued.—S. S. G.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Farnham-street, Bolton, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruit for naming; these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Chrysanthemums—when to retain the buds (H. S. T.).—Each of the varieties in your list should have their buds retained until the plants have developed on the plants. An ideal time for most varieties is the latter part of August, and buds forming about that period invariably give good results.

Size of tennis court (A Constant Reader).—The court should be 28 feet long and 27 feet wide for a single-handed game, and for a double-handed game, 74 feet long and 36 feet wide. It is divided across the middle (of the length) by a net, which should be 3 feet 6 inches high at the posts, and about 3 feet at the centre. The ball court line is halfway between the side lines and parallel with them. The service lines are 21 feet from the net and parallel with it.

Annuals for the flower garden (A Constant Reader).—A garden may be made very gay in summer with half-hardy plants raised from seed. These include Stocks, Asters, Marigolds, Lavatera, Zinnias, Verbenas, Heliotropes, Petunias, Phlox Drummondii, Dianthus, Ageratum, Pyrethrum, Lobelia, and Begonias, which may be sown in heat early in the year. Those when pricked out thinly into cold-frames or boxes and hardened off can be planted out in May. To flower in the spring you should raise a stock of Polyanthus, Myosotis, Wallflowers, Silene, Violas, Iceland Poppies, Saponaria, Digitalis, etc.

Remaking a lawn (Harold Smith).—The first thing you will have to do is to see that the lawn is well drained. Break up the surface several inches deep early this month, make it firm and level, then sow some good Grass seed, and with it a light dressing of any suitable artificial manure, well raking it in and rolling the surface well. By the end of October you should have a good green sward, which could remain untouched all the winter. Falling sowing in the autumn or re-lurding, prepare the soil and sow next April. Seeing the soil is very stiff, a liberal dressing of gritty street sweepings, if such can be had, would be beneficial.

A north aspect conservatory (Cermos).—Undoubtedly your greenhouse is at a disadvantage at a certain time of the year because it is on the north side of the house, but it gets a fair amount of light in the summer and does not need shading. Hence you should be able to flower in it in the summer Fuchsias, Geraniums, Petunias, Begonias, Heliotropes, Roses on the back wall, and climbers at the ends, such as the Trumpet Honeysuckle or the blue Plumbeago capensis. It would be unwise to have climbers on the roof with your aspect. You would find most Ferns, some of the birdier Palms, such as Kentia Fosteriana, Phoenix reclinata, and others do well, and such fine-lobed plants as Aspidistra lurida variegata, the India-rubber-plant, Aracaria excelsa, Ophiopogon, Aralia Sieboldi variegata, and similar fine-lobed plants do well all the year round.

Planting window-boxes (Ignorance).—We fear you will find few sweet-smelling plants suitable for a window-box in the winter, but if you plant first, after the box has been properly filled with good loamy soil, some Hellebores, these will give strong perfume in the spring. You can also plant just a few bulbs of Stella or other single-flowered Narcissus. Plant all those 3 inches deep. Then get to front the box and hang down plants of Creeping Jenny, and at the back just a few Wallflowers, and cover the rest of the soil with Pansies or Violas. That will give you a green effect in the winter and plenty of pretty bloom in the spring. Sow very thinly in 5-inch pots, properly drained and filled with soil, seeds of Mignonette, Nemophila, dwarf Sweet Peas, one or two varieties of Clarkia, and any other dwarf-growing annuals. When the plants are a few inches in height, they may be planted in the box after it has been emptied of winter things and refilled with fresh soil. This would be at the end of May. Sow the seeds in the pots under glass in April, or, if outdoors, then early in May.

Creepers for a glazed corridor (Fitzstuart).—From the following list of good flowering climbers suitable for clothing a verandah you can make your own selection: Bignonia radicans, red trumpet-shaped flowers, borne in July and August; Clematis montana, pure white starry blossoms, in early spring; Clematis Jarkman, rich purple flowers, towards the latter part of the summer; Clematis lanuginosa candida, blooms large, pale mauve, summer; Psephenia suspensa, yellow, end of February and in March; Jasminum nudiflorum (the Winter Jasmine), from the depth of winter till spring, flowers yellow; Jasminum officinale (common Jasmine), pure white scented blossoms, summer; Lonicera japonica, whitish, very fragrant; Honeysuckle; Lonicera xylosteum, evergreen; Honeysuckle, with red and yellow trumpet-shaped blossoms; Passiflora coriacea (early blue Passion flower) blooming in summer; and P. Constantia Elliot, a white-flowered counterpart of the

VEGETABLES.

BLANCHING CELERY.

It matters little how well Celery may have been attended to previously if the blanching is not well carried out. It must also be borne in mind that, although blanching is all-important in the production of good edible Celery, yet the foundation must be laid beforehand to ensure good solid hearts pushing up. If the plants are small or undersized for the variety, however carefully blanching may be done, good solid-hearted Celery will not be obtained. For this reason, if the plants should be now undersized, it will be much better to encourage growth as much as possible before any soil is added, unless it should be as a top-dressing, by keeping the trench in a well moistened state with an occasional application of liquid-manure or a light sprinkling of salt. Nitrate of soda will also hasten on the growth of backward Celery. With the growth active and well up to time, clear water will be ample, and with a free use of liquid-manure or of nitrate of soda the plants become coarse. Over-feeding Celery leads to inferior quality, and is also against its keeping well after earthing up has been completed. Huge sticks may certainly eventually be had, but on the approach of winter they quickly suffer from damp, and when this sets in the leaf-stalks decay wholesale. Moisture being a necessity for the securing of high quality in Celery, must have attention before earthing commences, for although it is possible to water Celery after the first earthing, yet with the soil in a well moistened condition prior to this operation, it invariably keeps moist enough afterwards to lead to a satisfactory after growth. The first earthing must not be confounded with an ordinary top-dressing, after which water may be applied as often as before. Before blanching proper commences the trenches should be well watered, giving sufficient so that the soil is thoroughly moistened. Earthing up Celery with the soil about the roots in a dry state, if it does not exactly lead to bolting, renders the quality poor, the heads being tough and insipid instead of crisp, sweet, and nutty in flavour. There is also the danger of being in too great a hurry with the blanching. A good guide is to have sufficient well in hand for use, the blanching of that which is needed for the main winter crop being left some time longer.

MODE OF BLANCHING.—Some growers have their favorite methods of blanching, such as surrounding the stems with stout brown paper, or collars purchased for the purpose. Others go to the trouble of surrounding the stems with sand, ashes, and burnt soil, but whatever advantages these may have, well-worked soil is the most generally used, and, besides being the most convenient, invariably results in securing well-blanching produce. Heavy soils are supposed to be the worst to deal with, but with a free use of lime and burnt refuse mixed with the staple in the ordinary course of cropping, there is no difficulty in this respect. If, on turning up the soil for earthing, it should prove lumpy, the best addition is to wheel some burnt refuse

along the sides, this being worked in with the soil as it is being thrown up, of course taking all ordinary precautions to get it as finely divided as possible. As fresh soil is added, the plants should be drawn up together and tied with a piece of matting, as this will prove a much more convenient method than having one person to hold each up separately whilst another adds the soil. Three earthings are generally sufficient, and these at intervals of a fortnight. After each earthing, take care that the matting is cut away, for if this were allowed to remain the hearts would become crippled. To ensure a clear growth after earthing, the hearts, except at the final earthing, must be kept in advance of the soil added, or there will be danger, if the stems should be heavily weighted with soil and the hearts thereby enclosed, of the stems bulging; consequently the heart growth would be cripple. At the final earthing use plenty of soil as a protection from frost, taking care, however, that the sides of the ridges are brought up sharply and made smooth, this being an excellent protection from wet. It is when the soil is thrown up loosely with a rough outer surface that the wet penetrates. As a safeguard from slugs, salt is a good antidote, a little being sprinkled over the soil at the first earthing. Lime may also be used for dusting over the soil at each earthing, or even soot may be used.

PRESERVING SEED POTATOES.

THE aim of all growers ought to be the careful preservation of the seed-tubers, now being stored, in as dormant a state as possible. Nothing in the shape of a heap should be formed. At lifting time let them be separated from the wery and quite the smallest Potatoes—good medium-sized uncut tubers being the best for planting—and kept stored thinly till next spring. Greening Potatoes by exposure to the light and air, is so far advisable, inasmuch as it slightly retards sprouting, but this ought not to be brought about by leaving them for several days or weeks lying on the ground or on paths, boards, or mats in the open, as by planting time not a few of the tubers may have taken disease between the lifting and storing times, this being effectually hidden by the coat of green. Tubers thus diseased do not decay rapidly, and perhaps the first indication of its presence is in many cases the weakly growth of the sprouts. Diseased sets cannot support a strong growth of haulm till it has time to become self-supporting, and ought never to be planted. Disease germs are far more plentiful in the air than most of us are aware of, but if they cannot reach the tubers before their skins are dry and well set they will not affect them afterwards, always provided the Potatoes have been properly stored. Dig all tubers that are to be stored in dry weather, and while also the ground is in a semi-dry state. This admits of the tubers being placed under cover or in heaps, and lightly covered up almost as fast as they are dug. It is a mistake to leave a lot of newly-dug Potatoes on the ground to dry all night. Sprouting must be prevented as much as possible

by storing thinly as well as exposing the tubers to light and air. Keeping them in single layers, resting in the case of Ashleaves on the smaller end or that previously attached to the plant, cool end fairly light, is the best preventive of premature sprouting and also the surest way of having the sprouts stout and strong when the proper time arrives for growth to be made. Shallow trays with the corner blocks 2 inches higher than the sides are very handy for storing seed tubers in, as these can be packed one above another and yet not unduly shade each other. Any kind of flat box or shallow basket blocked up well one above the other is preferable to storing in deep boxes, hampers, and suchlike. The tubers should at planting time be quite firm and the sprouts short, yet how often do cottagers turn them out from a spare room or elsewhere all matted together and shrivelling. Protection must be afforded during severe frost, and if the room or outbuilding when closed cannot be depended on to protect sufficiently, then mats, blinds, straw litter, or even several coverings of paper, should be used as well.

NOTES AND REPLIES.

Pea William Hurst.—Of the many Peas in cultivation I consider this to be one of the most valuable for small gardens. Coming midway in height between the very dwarf and the taller-growing kinds, it can be grown either with or without sticks, according to the option of the cultivator. It appears to be one of the most reliable Peas we have, not being so liable to go off in the provoking way that is characteristic of some of our finest kinds. For some years I have grown this Pea almost to the exclusion of all others, as by sowing at intervals of ten days or a fortnight from the beginning of March, I have been able to maintain a good successional supply without being obliged to have recourse to the troublesome process of staking.—J. C. B.

Tomatoes setting badly.—Here, in the West of England, many who have only an open piece of ground (and this sometimes in allotments) grow a few plants, and this year from present appearances there will be very little fruit. I have not seen any plants in the open with a fruit set on them, although I have seen them in a good many gardens in flower. Even where the seedlings were raised early and strong plants put out at the end of May against sunny walls there are but few fruits set. I put out plants 18 inches high against a south wall at the end of May, but these are only now growing freely and are full of bloom. I have found that fruit set after September comes in is of little value here. In cold-houses the plants grow freely but fail to set, and I have plants 6 feet high growing in a cold, airy house with only three or four fruits on a plant. In some instances bunch after bunch of flowers has failed to set. Up to the present time I have not cut more than a third of the crop that I have had from the same space in some years. Disease is attacking them in many instances. This is not to be wondered at, seeing how severely the Potatoes have been attacked this year.

OUTDOOR PLANTS.

DELPHINIUMS.

AMONGST our taller border plants none command greater admiration in their time of flowering than Delphiniums. Few herbaceous perennials demand less attention, if planted in well-prepared soil, and if a careful selection of varieties is made, one may have blossoms for months. Not only is it a flower that makes attractive the country garden, but in towns, where some other hardy perennials do little more than exist, the Delphinium will thrive and add colour to the border. Whilst there are many varieties possessing delightful shades of blue, we are not restricted by any means to that particular colour, as white, pink, red, and purple shades are now well represented, and for cutting and placing in jars they are extremely useful.

PROPAGATION.—There are two methods at least by which propagation may be effected—the first is by sowing seed in March or April in cold-frames, pricking off the young plants into boxes, when large enough, and subsequently transplanting them into the open, in well dug and manured soil, paying special attention to them with regard to watering, keeping the surface between the plants well stirred, and encouraging growth generally. Treated thus, many will bloom the same season, and from seed purchased from a reliable source a good proportion of meritorious flowers results. Young plants of the first season's growth, after the flowering stems have been cut away, should have some slight protection, and rough leaf-soil or ashes, placed about the crowns, will be sufficient—ashes, perhaps, are better than leaves, as they not merely protect the plants from frost, but are often a preventive of slugs attacking the young growths. Seed sowing is not much practised in private gardens, as the many beautiful-named varieties we have to-day are so reasonable in price as to be within the reach of all who desire these stately border plants. From twelve to twenty plants in a garden are usually sufficient, and these, if procured and planted in the autumn will be ready for dividing in a couple of years—in fact, three or four years at the most are enough for them to be left to themselves, as after that period they get large and bulky, and have used up much of the nutriment of the soil, and need a change of position and compost. This dividing is best effected by digging up the clumps and severing them with a knife or spud. In planting it is well to group two or three varieties together, leaving, say, 12 inches to 15 inches between each clump, as by so doing they make a charming show when in bloom. Too much attention cannot be paid to making the soil ready for the clumps. This is best done by digging in some turf, well chopped up, and partly rotted dung, as Delphiniums being gross feeders, it is useless to put them into an impoverished soil at the start, and a mulching of manure in the autumn will also be of immense benefit. Early in the summer arrangements should be made for staking the plants, as if this is not done, in wet and windy weather the tall shoots break off. It is a little more trouble to give each shoot a separate stake, but it is advantageous to do so, as then each has freedom to bloom and develop properly, which is not so when one stake only is used, and all the stalks are bunched up to it, a very common but somewhat rough and ready method. A second lot of fair-sized blossoms may be had in the autumn, if, after blooming, the plants are cut down and well manured. In a dry season it is imperative that Delphiniums should be well supplied with water, and liquid manure will greatly help the buds.

—These are deserving of cultivation in every garden. The great variety of their heights, varying, as they do, in this respect, from 1 foot to 6 feet high, the equally great variety of their shades of colour, from almost scarlet to pure white, from the palest and most chaste lavender up through every conceivable shade of blue to deep indigo, and the variety of size and

form of their individual blooms, some of which are single, semi-double, and perfectly double, and set on spikes ranging from 1 foot to 6 feet in length, render them objects of great value as border plants. For cutting, either in immense spikes for some forms of decoration or in smaller lateral twigs for bouquets and vases, they are most useful. The combinations in which they can be placed in borders are numerous. When planted to back up a mixed border the effect of the Delphiniums and any light-foliaged or flowering plant is very charm-

the winter in some sandy soil in a corner, where they can be more conveniently seen to. This is only necessary until they form large and vigorous stools. It is well to lift them every two or three years and thoroughly work the ground, adding some leaf-mould or manure, and then to replant them. This is best done about the time the crowns begin to move in early spring. In favourable seasons, if they are not allowed to seed, they generally throw up a second crop of flowers late in the season; and the spikes being smaller and more twiggy,

Delphiniums. From a photograph taken at Gravetye Manor, Sussex.

ing. Delphiniums are, of course, perfectly hardy, and can be cultivated in any ordinary garden soil. They are propagated from cuttings detached from stools when 6 inches high, or when the stools become large they can be lifted and divided like any ordinary herbaceous plant. The ground for them should be rich, open, and deep. When young plants are put out in spring in soils where slugs abound, the buds or crowns are apt to be devoured by them in winter; consequently it is well, under such circumstances, to lift them and lay them in for

they are then most valuable for cutting as well as effective in the borders. Delphiniums are now in fine bloom, and anyone requiring to select the best kinds should visit some of the large hardy plant nurseries at once. When the flowers begin to fade, the stems should be cut down to the ground and the plants have a good soaking of water, they will then throw up fresh spikes of flowers in autumn. A packet of good seed sown in May or June will produce good plants for flowering in the following year.

T.

AURICULAS.

AURICULAS may be divided into three classes—namely, alpine, border, and show. The two first are charming garden flowers, but the last can only be successfully cultivated in pots. Alpine Auriculas are divided again into two sections, those with grey or white centres, and those with yellow centres. A native of the high Alps, the Auricula is by nature a perfectly hardy plant. Old specimens of border varieties may be met with in gardens that have been undisturbed for years, and have formed large tufts both on stiff clay soils and in a lighter and more porous staple. These old plants are best divided towards the end of March, lifting the entire clump carefully, shaking it free of soil, and parting each separate crown, which should at once be planted in fresh soil. In raising from seed, this should be sown in boxes in the early spring in a gentle heat of about 50 degs. Good drainage should be provided, and over this fibrous loam and leaf-mould in equal proportions placed, the top inch of the compost being a mixture of leaf-mould and sand. When the seedlings are large enough to handle, they should be pricked out and placed 2½ inches apart in other boxes or pans, removed to the open air in the late spring, and planted out in a partially shaded border after mid-summer. In scorching weather artificial shade is beneficial to the seedlings. These remarks apply to the alpine and border Auriculas, and not to the show varieties, which are always grown in pots.

Everyone who grows Auriculas should raise plants annually from seed, for it is a sportive flower, and there is always a chance of raising seedlings that are far more beautiful than their parents, and in this manner strains may be immensely improved in the course of a few years. As better varieties are obtained, the washy, badly-colored, or weak-habited plants should be weeded out. What is required of a border or alpine Auricula is clear markings, bright colour if a self, sturdy, erect stems, and free-flowering habit, and in these there is still room for further improvement if careful cross-fertilisation be practised. Show Auriculas are divided into five sections—namely, selfs, white-edged, grey-edged, green-edged, and fancies, the last section including flowers that, though often pretty, may not be admitted into any of the other four sections. The foliage of the show Auricula is covered with a mealy substance, and portions of the flowers with a white, floury powder. Thus the centre of the flower is yellow; this is surrounded by a ring of farina, outside of which is a ring of dark colour, beyond which is an edging of green, grey, or white. This outer edging is, in fact, a development of leaf-like properties in the petal. In the green-edged this is unpowdered, but in the grey-edged and white-edged the green is covered with a white powdering, the density of which powdering constitutes the difference between the white-edged and grey-edged sections. Alpine Auriculas are destitute of powdery matter on their petals, as are those of the border section, which may be termed less refined alpine Auriculas. S. W. F.

TUFTED PANSIES—SELECTION OF PROVED SORTS.

So many lengthy lists of Tufted Pansies are issued that the inexperienced grower becomes bewildered when endeavouring to compile a list of the best. Each season sees additions to the already long list of sorts, and, that intending growers may be helped in making a good all-round selection, the present opportunity is taken to give their names and descriptions.

This should enable the would-be grower to determine those sorts best suited to his requirements. For the next two months propagation by cuttings will be largely practised. The more noteworthy varieties are given prominence under the heading of their respective colours:—

WHITE.

WHITE EMPRESS.—This variety is also distributed under the name of *Blanche*, and as a good robust and free-flowering creamy-white sort it is superb. The blossoms are large and rayless, and possess plenty of substance. It is also a most continuous bloomer.

SEAFIELD.—A very beautiful pure white, rayless flower, with an extremely neat yellow eye. The plant has a very good dwarf and compact habit, and is free-flowering.

ELAINE.—This is a large pure white flower, with a suffusion of yellow on the lower petal. The blooms possess plenty of substance, and are developed on a splendid length of footstalk. It is free-flowering, and the plant has a capital constitution.

EDWARD MASON.—This variety does well in the warmest weather. The flowers are pure white with a neat yellow eye, and rayless. The plant is a very free bloomer, and possesses a beautiful habit of growth.

bright yellow self, has achieved distinction. The plant has a creeping-like style of growth.

KLOSDYKE.—The modern florist would probably find fault with this flower, yet the free manner in which the blossoms are developed appeals to all who have seen them. When massed the effect is very striking. Colour, clear yellow, rayless.

PENSER D'OR.—Unfortunately, there is very little stock of this lovely variety obtainable. The habit is all that could be desired, and the plant is a profuse bloomer. The deep rich orange-yellow colour of the flowers is one of its chief charms.

BLUE.

PHOENIX.—This is not a large flower; in fact, it is one of the miniature sorts. The plant, however, is very free-flowering and has a good habit. For edgings this plant has a special value. The colour may be described as deep heliotrope-blue, and the flower has a neat yellow eye.

KING OF THE BLUES.—This excellent kind is one of the late Dr. Stuart's raising, and is the best true blue sort. The flowers are of small to medium size, and the beautiful deep blue colour is enhanced by the bright yellow eye. The blooms are rayless, but are heavily veined in the centre. Habit good, and also a free-flowering kind.

An alpine Auricula. From a photograph by Mr. Jas. E. Tyler, Hantshead, Essex.

CREAM KING.—A novelty of the present season, in which the rayless blooms are very large and circular, and of splendid substance. The colour may be described as a rich creamy-white, with a brilliant orange eye. Extra strong growths are benefited by having their points pinched out occasionally.

PENSCITLAND.—This has had a good trial and is now recognised as a very useful kind. It is a pure white sort, and is slightly rayed.

YELLOW.

KITTY HAY.—In this the colour is a particularly striking shade of yellow, and is most effective when the plants are grouped in quantity. The flowers are rayless, and the plant is a profuse bloomer.

MELAMPUS.—In this plant we have a kind with a perfect habit, and this, together with an erect flower-stalk, carrying the blossom well above the procumbent foliage, makes it a distinct acquisition. The flowers are of goodly proportions and rayless, colour deep yellow.

ANDROMEDA.—This is a 1900 novelty, of which but little is known. The flowers are very large, and the colour may be described as bright yellow, with a deeper shade of yellow on the lower petal. With age the blossoms pale off to a primrose on the edge of the upper petals. The plant has a good tufted habit.

BLAND G. SINCLAIR.—Although only distributed in 1901, this variety, a free-flowering

BLUE GOWN.—If good pieces of this delightful Tufted Pansy can be secured, there is no better. The habit is ideal, and the plant flowers freely. The colour may be described as mauve-blue. Rayless.

OTHER COLOURS.

FLORIZEL.—No collection can be considered complete without this variety. The smallest pieces will develop into handsome plants which will bloom freely. The colour is a shade of blush-lilac and the blooms are rayless. Habit perfect.

VIRGINIA.—A refined and beautiful flower of a pleasing pale blush colour and rayless. The habit is dwarf and compact and the plant blooms freely.

COUNSELLOR W. WATERS.—This has a good habit and is free-flowering. The colour is rosy-purple.

MAGIE.—This variety is often printed as "Maggie," but the name given in this instance is the correct one. It is a large, deep rose flower, paling somewhat in the warmer weather, and it has a neat yellow eye. Habit compact and fairly dwarf.

DUCHESS OF FIFE.—This is generally considered one of the very best of the margined flowers, the colour in this instance being primrose, irregularly margined blue. The habit of this plant is dwarf and crawling, and each plant develops into a large clump. Two other

members of this same family are Goldfinch and White Duchess, and these are slight variations from the variety under notice.

CROWN JEWEL.—This is somewhat similar in its markings to Countess of Kintore, so well known. In this case, however, the colours are brighter and the habit is far better.

D. B. CRANE.

NOTES AND REPLIES.

Gladioli.—Messrs. Kelway and Sons, Langport, have just sent some beautiful spikes of Gladioli, the flowers richly coloured, large, and of fine form. Among those sent we note: Frank Miles, bluish, flaked carmine; Edward VII., scarlet crimson, light centre, an immense, well-formed flower; Cellini, maroon, with dark spot in the throat; Lord Milner, red, spotted yellow in the throat; Sir Chas. Russell, orange, with yellow throat; and Matengo, a fine flower, bright scarlet, striped violet. No garden should be without the Gladioli so rich and varied in colour and effective when the summer is merging into autumn.

Planting flowers and Ferns on walls.—Take two cupfuls of very fine, dry soil passed through a sieve, place in a basin, and make into a moist cake with water. Continue to stir this while you sprinkle all over it hardy Fern seeds, rock plants, Wallflower, Snapdragon, and other seeds, of which any seedsman would give you a mixture. Mix all well together, and then place very minute dabs of it into small fissures in a wall that is, if possible, backed by a bank. Have another basin of moist soil and fill in the cavities with it with a round-topped knife, putty-knife, or oyster opener. August is the best month for doing this.—E. MAY.

Sea Hollies (Eryngium).—I have to-day been cutting my first lot of Sea Hollies, and although they last for many months when taken indoors, there is just a possibility of leaving them too long before gathering, and so losing their beautiful colours. I know people, who contrive to keep up their supply of cut flowers as long as possible in the autumn, who know nothing of Eryngiums, and yet in them we have flowers that have a charm of their own, and will add interest to a room all winter.—W. F. D.

Using weed killer near well.—Will you kindly give me your opinion in GARDENING ILLUSTRATED on the following point? The water supply of my house is derived from a well sunk in the middle of the garden, and conveyed by pipes to pump in yard, and thence to the house. The well is sunk in solid rock, with exception of about 5 feet at the top, which is built up with bricks and mortar, and the top covered with steel rods and sheet iron, and Grass growing over all. The well is about 25 feet deep. I can safely use on the garden walks a weed killer, of which the active ingredient is arsenic? If there is danger of the water becoming poisoned, at what distance from well might it be safely used? I shall be greatly obliged for your opinion.—W. M. G.

[Under ordinary circumstances a well would be safe if the arsenical weed killer were not used at any point nearer than 50 feet or 60 feet from the well. But there is always the possibility that, owing to the accidental spilling of the stuff or to the occurrence of heavy rain soon after it is used, the water of the well might receive traces of the poison, and as this might do serious mischief, and would not be an easy matter to mend, it would be safer not to use the weed killer at all in such a case.]

An experience with Verbenas.—A comparatively sunless summer is not likely to rid plants that enjoy and flower best in warm weather, so it is that some who have grown Verbenas this year have not been satisfied with them. Even in a season like the present one can record exceptions, and one at least which came under my notice was where the plants, which were raised from seed sown in boxes in March, were potted off, and instead of their being turned out of the pots in June, were plunged on a rather dry border. The result has been a most satisfactory one, for whilst others which were set out in the usual way have made a preponderance of wood and very little bloom, those plunged in pots have flowered well, presumably because their root action was curtailed somewhat. At any rate the difference has been most marked.—W. F. D.

Begonia Worthiana.—Kindly tell me the name of this Begonia, flowers of which I send? When fresh it was a lovely coral-red, standing erect, about 8 inches high, and looking rather like a *Fuchsia*. Also, would you say how a supply can be got—by seeds, bulbs, etc.—and when one should begin, to ensure about 800 plants by June next?—AUSTRALIA.

[The enclosed specimen is *Begonia Worthiana*, which has of late years become very popular for bedding purposes. It can be raised

from seed, and to obtain about 800 plants by June next the seed should be sown by the latter part of February, in a temperature of 60 degs. to 70 degs., and given the treatment usually accorded to *Begonias* of the tuberous-rooted class—that is, pricked off when large enough to handle, and in time potted off singly into small pots. There is, of course, a certain amount of variability in the case of seedlings, and in order to ensure absolute uniformity many increase this *Begonia* by cuttings in the spring. The young shoots when about 3 inches long form the best of cuttings. One-year-old bulbs make a finer display out-of-doors than those raised the same season, and as most growers who make a speciality of bedding plants grow this *Begonia* largely, it is very probable that during the dormant season you might obtain them at a cheap rate.]

Michaelmas Daisies.—Some few plants in our gardens have special claims upon us, and we give them attention on the approach of their blooming seasons. We may mention in this connection *Roses*, *Carnations*, *Chrysanthemums*, then why not specialise a little more the *Michaelmas Daisy*? Who thinks of feeding it with liquid manure, or shuddering it, or even tying it up properly? Few, I fear. We somehow think that any scant treatment will do for this hardy autumn flower. I suggest to those who have not tried the plan to notice the difference in plants that are manured, buds thinned, and staked properly, as against neglected roots.—LEAURIST.

Lawns—autumn treatment.—We are often particular in cutting and rolling our lawns in the early summer in order to obtain a good sward, but many, I think, give less attention to the matter in the autumn than they should do; consequently, *Dandelions*, *Plantains*, *Daisies*, etc., no longer kept in check, grow apace, and the whole plot becomes weak and patchy. All lawns should be gone over at this season, ridding them of weeds, and be mulched with rotted manure after the last cutting. Just now *Cucumber* beds are being disturbed, and such manure as a winter dressing will be found of great value. Soot, too, after it has stood out-of-doors a few months and has lost its heat, may be dusted over the Grass with beneficial effects. It not only improves its colour, but keeps worms from coming through the surface.—LEAURIST.

Gardens ridiculous in design.—The photos of Drumlanrig in *Country Life* for August 23rd might well be a lesson for all who care for the garden as to what to avoid both in design and planting. They show a hideous waste of ugly pattern beds, with nothing in them but scraps of miserable plants, costly and wearisome *Stone Worts* out of place, and all the ugly aspects of the bastard Italian gardens as understood in North Britain. Not a thing is visible in these photographs showing any beauty of form of tree or plant, any grace of true design, or of the simplest skill in adapting the designs to the ground. If one thinks of the cost of all this hideous rubbish, and its effect on the minds of the many who, seeing it, mistake it for what is best in gardening, one cannot but deplore the stupidity that mistakes it for art or endures it as a foreground to a fair landscape.

Banks transformed.—In country gardens more particularly is the need soon for taking in hand banks, often near to the house and on either side carriage drives, etc. If neglected they quickly get into a bad state. If covered with turf it either becomes dried up or patchy, or, as is often the case, is neglected from want of cutting, because one cannot conveniently run the machine over it. Under all the circumstances, banks should come under cultivation to make the most of them, as by planting what is suitable they may be made very effective. No time is better than the autumn in which to commence, and one should see to it that the soil is as deep as possible, and not, as is often the case, have banks made up of all kinds of rubbish. *Wallflowers*, *Canterbury Bells*, *Antirrhinums*, *Foxgloves*, *Primroses*, *Ivies* in variety, are some of the subjects which occur to one as suitable for planting now, whilst in the spring, *Poppies*, *Nemophila*, *Mignonette*, etc., may be sown. On shady banks *Ferns* may be made much of, and *Ivies* should be planted for an edging.—LEAURIST.

ARRANGING DAHLIAS IN VASES.

EACH section of *Dahlias* seems to have its allotted place in indoor decorations, and for this reason it is well to consider where the different types of the flower may be seen to advantage. Most gardens possess a few plants of some form or other of this useful flower, and as they blossom so freely one is rarely at a loss to refill the vases and other receptacles, when their somewhat fleeting beauty is over.

The large double flowers of the show and fancy types are very handsome when at their best, and a bold effect may be made with a dozen flowers in a large vase. But for such work they should be cut with long stems and a few pieces of foliage attached, with a bud or two to stand out from this to relieve the heavy character of the arrangement. Of course, plants grown for exhibition would be severely disbudged, everything going to size; and because of this fact it might be a difficult matter to secure additional buds. However, in most gardens sprays of the kind I have just described may always be had. The stems may be kept in position by inserting between them nice fresh pieces of green Moss. On no account bunch the flowers together, but instead arrange them gracefully, so that each bud, flower, and piece of foliage can be seen. It is surprising what a splendid vase may be arranged in this way, a dozen sprays giving a rich effect. The fact that the blooms are cut with their own foliage adhering to the long stem is ample embellishment in the way of foliage. Small vases and specimen glasses, each to contain one specimen bloom, are seen to advantage on the mantelpiece or dotted about on the dinner-table, and in the numberless ways in which small utensils are now used. The *Cactus* and decorative types of the flower are each year becoming more popular, and deservedly so. The *Cactus* type of the flower is very pretty and effective.

A table decoration composed exclusively of the *Cactus Dahlias* makes a superb arrangement. There are so many warm tints of colour, which, seen under artificial light, produce rich effects. For a centre-piece, or any of the larger vases on the table, long stems with foliage and buds become a necessity; but these are easily fixed in position with a little Moss. A much better effect is obtained if each type of the flower be arranged by itself, the beauty peculiar to each kind being by these means better appreciated. For this reason the *Pompon* and the single-flowered sorts are the best. The former are always very pretty by themselves, and being neat and so freely produced the supply from a few plants seems almost inexhaustible. The singles, unfortunately, fall soon, but for an evening's display they last well indeed, and make a pleasing change.

When arranging the colours the softs may be associated together, and an opportunity afforded to make a change with some of the fancy-coloured sorts on another occasion. The yellow, orange, fawn, and crimson flowers are magnificent under artificial light, while the white, pink, and light shades of colour are seen to advantage during the day. Flowers of lilac, rose, and magenta look well under artificial light, and either one of these colours by itself, with white for a contrast, is effective. T.

Sweet Peas arranged in a bowl.

At the August meeting of the National Amateur Gardeners' Association, a class for a bowl of Sweet Peas was this season provided, for which two prizes were offered. Seven exhibits were forthcoming, and of this number five were really pleasing. The first prize exhibit was charmingly arranged. Each spray of blossom was deftly adjusted in position, and there was no crowding. Interspersed in a most delightful manner were pretty pieces of Sweet Pea haulm with buds and foliage standing out in bold relief. The colours were beautifully blended, and the display being made under artificial light, the brighter and richer shades of colour were very effective. It was a splendid illustration of the decorative value of the Sweet Pea when arranged with a proper regard for colour. There were others in which there were flowers of better quality but indifferently arranged.—W. V. T.

ROSES.

CLIMBING ROSES.

If we look at southern Continental gardens which enjoy a warmer climate and more constant sun, we shall find such climbing masses of beautiful Roses which will cause us to regret the absence from our English gardens of these luxuriant masses, that neither require nor obtain any special care from one year's end to the other. If the Roses that produce such glorious effects in foreign gardens are not hardy enough for us, why not try to raise new varieties that will stand our cold and changeable climate? We have *R. sempervirens* (here figured), and the several garden varieties, such as *Felicité-Perpetue*, that will climb a pillar or rail over an old outhouse or shed. The *Arvshire* Roses (*R. arvensis*) and the varieties of *R. alpina*, though very beautiful, only bloom during the summer. We have also the Spanish *R. rugosa* and its many forms, the

sent the photograph from which our illustration was prepared, has kindly sent the following note—

"The Rose (*sempervirens*) was planted against an old Pear-tree at the end of a large corrugated iron shed, and was first allowed to climb for some little time in a rough way up the Pear-tree, but afterwards I covered the top and both sides of the shed with coarse wire netting, and tied out as many of the Rose shoots as possible, thereby getting the pretty effect which is shown in the picture. Everyone who has seen it has greatly admired it, and I am sure if readers would beautify all garden outhouses in the same way, they would be well rewarded for the little time necessary and small outlay."

NOTES AND REPLIES.

Roses shedding their foliage (F.M.).

—We think that your trees suffered from the

smooth-wooded *Victor Verdier* tribe. We should advise you to plant more of the Tea and Hybrid Tea Roses, which are never infected like those you describe. The above recipe for destroying the resting spores of the fungus was gathered from an article by a very able scientist, Mr. W. G. Smith, F.L.S., which appeared in the "*Rosarian's Year Book*" for 1887. We do not think your plants were weakened by the luxuriance of the first crop, unless you gave them overdoses of liquid-manure, the evil effect of which would show itself only after flowering.

Pompon Rose "De Meaux."—The miniature *Provence* or *Pompon* Roses are a very interesting group of *Rosa centifolia*. Flowering as they do with the Scotch Roses, their diminutive little flowers were never more welcome than this year, when all other Roses appear two to three weeks later than usual. *De Meaux* produces its charming little blossoms very plentifully, the shoots bearing the flowers rising one above the other, which

Rosa sempervirens clambering over corrugated iron shed. From a photograph by Mr. G. H. Towndrow, Malvern Link.

double *R. Fortunei* and the beautiful *R. banksiana*, the parent of the so-called large white *banksiana* Rose *Fortunei*. Then, again, we have the monthly or China Roses, which are vigorous in growth, hardy, and most constant bloomers, often continuing to flower until winter. Of all the China Roses *Madame Laurette Messimy* is, perhaps, the most distinct variety that has yet been raised. Among other good kinds we may mention *Cramoisie-Superieur*, *Eugene Desal*, *Hermosa*, and *Fellenberg*. Let us use what we have and plant in the wilder parts such hardy kinds as we have mentioned. When a warm wall needs covering the *Banksian* Rose or the various hybrids of the Tea and *Voisette* may be used, though they are liable to suffer in cold situations and seasons. For sweetness what can rival the lemon and white clusters of *Lamarque*? *Aimée Vibert* should be in every garden. What, again, among the roses with the Tea blood in them, can equal *Leve d'Or*, *L'Idéale*, *W. A. Richardson*, *Mme. Alfred Carrière*, *Gloire de Dijon*, *Mme. Berard*, or *Celine Forestier*?

Mr. Geo. H. Towndrow, Malvern Link, who

artificial watering rather than from red-rust. Of course, it is quite possible for Roses to have an attack of red-rust thus early, and this would be owing to a bad attack the previous autumn. The resting spores of this fungus will lie on the ground and reappear in spring in a pale sulphury state, changing about mid-summer to the orange colour so well known. If you succeeded in banishing the fungus from your garden, your plants would still be liable to infection from the hedgerows. A good preventive is to rake off in autumn all decayed foliage and a thin layer of the surface soil. Let this be burnt. Then give the ground a good dressing of quicklime. You can return the burnt earth to the beds. At pruning time all shoots should be collected and burnt, and the growths of the plants dressed with the following mixture: Quicklime and soot, mixed to the consistency of paint, in a pailful of which add half a pound of sublimated sulphur and a handful of coarse salt. Stir well together before applying, the object being to destroy the resting spores. Many Roses are badly addicted to this fungus, especially the

gives the plant the appearance of a floral cone. The colour of this variety is light rose with a silvery-white shading, the flowers possessing a most beautiful compact form. It is much grown on the Continent in pots, and would certainly be worthy of more extended indoor culture in this country. Plants raised from cuttings or layers retain the diminutive form much better than do those propagated by budding, and I should say plants of *De Meaux* would be very welcome for table decoration. The variety *Spong*, being larger, is not so interesting, but the white *De Meaux* is a delightful little Rose that everyone who possesses a garden should cultivate. There is a Moss Rose named *De Meaux*. Although small and charmingly mossed it is quite distinct from the Rose under notice. The miniature *Provence* Roses are not so much in demand now for edging as they were formerly, doubtless owing to being superseded by the dwarf *Polyanthas*, and also the Monthly Roses. These two groups, by reason of their free and continuous flowering habit, are, of course, more suitable.

INDOOR PLANTS.

FINELY-GROWN FUCHSIAS.

PROBABLY at no show in this country are Fuchsias seen better than at Trowbridge in August. At the late exhibition these were staged in goodly numbers. The season has apparently suited the plants well, judging from their vigour, freshness, and abundance of bloom. The majority of the plants ranged from 7 feet to 9 feet high, and in most instances perfectly trained and flowered from tip to base, their growth half-concealing the pots in which they grow. These are of large size, probably 14 inches to 16 inches in diameter, which, together with the weight of their heads, makes them the most cumbersome among exhibition plants. They must have careful handling, and be carried on open spring trollies to the shows, otherwise the flowers fall prematurely, causing irreparable damage and loss in their appearance. Mr. George Tucker, of Hilperton, has been a grower and the most successful exhibitor at the Trowbridge and Bath shows for many years. Some are, despite their striking proportions, less than eighteen months old. Aged plants are not retained, because greater vigour, better foliage, and larger blooms are obtained from young plants. Cuttings are rooted in the autumn, and kept growing all the winter in a warm temperature, and by the time when all fear of frost is past they are stood on the garden paths in the open. Needless to say, generous, though very careful, feeding must be practised, both to maintain and to promote a desirable vigour, and dryness of the soil must be at all times avoided. I noticed among the better plants, the varieties adapted to the purpose of exhibition included Masterpiece, Brilliant, Western Beauty, Arabella Improved, Charming, Lye's Favourite, H. Roberts, Mrs. Bright, Doel's Favourite, Amy Lye, and Mrs. Rundle. Apart from exhibition purposes, such plants would be desirable and very pleasing ornaments grown in pots, and plunged during the summer on the lawn or on broad Grass or gravel terraces. It would be necessary for the pots to be plunged, and the plants stood in sheltered spots where high winds could not easily reach them. Fuchsias are impatient of wind, and their height necessarily makes them easy victims to its force. W. S.

Keeping Geraniums through winter (H. A. J.)

You have given no information as to the conveniences you possess for wintering your Geraniums, nor as to the condition they are now in. The best position in which Geraniums may be kept during the winter is on a shelf, or a good light position in the greenhouse, where the minimum winter temperature does not at any time fall below 40 degs. If your question refers to Geraniums now planted out, the better way is to lift them as soon as they can be spared, cut back the very vigorous shoots, and remove the particularly strong leaves. In doing this, do not strip off the leaves, but cut them, leaving an inch or so of leaf-stalk attached to the stem. This will soon drop off and leave no scar, whereas if the leaves are stripped the stem is often injured and decay is liable to set in there. During the winter the soil should be kept slightly moist, but nothing more, as an excess of moisture will often prove fatal. If your conveniences are limited to a room in a dwelling house or a moderately dry frost-proof cellar, a different mode of treatment will be needed to keep old bedding Geraniums throughout the winter. They should be lifted and trimmed over as above detailed, then lay them rather thickly into boxes about 5 inches or 6 inches deep. The soil used should be nearly dry, and the plants will scarcely need any water till the spring. True, the leaves will all drop, but when the growing season comes round new ones will be pushed out, at which time, if possible, the Geraniums should be potted singly and any straggling shoots shortened.

While very anxious to answer all questions sent, we are often greatly handicapped by the absence of any details on which to base our answer.

CHRYSANTHEMUMS.

HOUSING THE PLANTS.

THE work which should engage our attention now is the necessary preparation for housing the plants. Before the hulk is ready there is sure to be here and there a plant the flowers of which are showing colour. Without a room or a delay place such under cover, for with damaged outside florets the beauty of a bloom may be marred. The mildew pest can be effectually dealt with at this time, and if each plant with any sign of it on the leaves be put on its side, sulphur may be puffed on to the under surface in a thorough manner. In the south, placing the whole collection under cover is generally started the last week of September, it seldom being safe to leave anything outside longer than a fortnight after. I have, however, found backward flower-buds swell better in the open air, and I never put a plant under glass to hasten it, but only for safety from frosts. Before the buds show colour they miss the night dews. Unfortunately, many of us are not over-long in the matter of glass structures, so that there is little choice as to positions. A

Philadelphus coronarius. (See page 377.)

well-ventilated span-roofed house is the one I should select for Chrysanthemums to bloom in, and I would so place the incurved sorts that they get less sun than the Japanese varieties. I would divide the latter in this way. There are many, including all the large, heavy, thick-petalled kinds, that appear to revel in the sun's rays, and need shade only in the morning till the accumulated moisture of the night before has been dried by air. Then there are the thin, many-petalled, delicate kinds, as well as very deep coloured varieties, which strong sunshine spoils. Such should be stood in the shadiest part of the house, or otherwise the sun kept from them. Stand the pots as far apart as room will allow. A capital plan with most of the incurved sorts is to take away their sticks and fasten them up the front and sides of ordinary greenhouses, vinerias at rest, and the like. In this position the foliage is close to the glass and the flowers become partially shaded, while the blooms, hanging their heads as it were, seem to take on the desired shape more evenly than when tied upright. When all are under cover fumigate each house on two or three occasions, whether aphides are seen or not. These are pretty certain to appear when fire heat is employed. There is no danger in fumigating, even when the blooms are opening, provided air be passed among the plants in early morning after the operation.

WATERING AND AIR-GIVING are important when Chrysanthemums are under glass. Allow the roots to get on the dry side for a few days, as the

inside conditions are so different from those in the open. During this time throw water among the plants if the weather be at all dry. When well used to being under glass more water at the roots will be required. The collection should be gone through twice a day. Feeding with stimulating manures is still needed, and may be continued till the blooms are well open. Be very careful, however, about feeding varieties of very high colour like Wm. Seward, or delicate growers like Mrs. Alpheus Harly. There is little doubt that over-feeding predisposes to damping in the blooms, so trouble some to many growers. Open doors and ventilators night and day, and gradually lessen the supply of air as the flowers open, so that cold draughts may not play upon them. A free current of air should pass through the house at all times except when fogs prevail. Growers of Chrysanthemums near London know what they mean and how difficult it is to prevent damage being done to opening blooms. At these times keep the ventilators almost closed and the pipes nicely warm.

Chrysanthemum "feast" at Tamworth.

—One of the chief events of the year in connection with the popularising of the early-flowering Chrysanthemums is what is termed by the originator of the idea a "feast" and this is to take place at Bellehall House, the residence of Mr. William Sydeham, on Saturday, September 27th next. This enthusiastic horticulturist has been at considerable pains and expense in planting a thoroughly representative collection of both Pompon and Japanese types of the early sorts. It is interesting to learn that quite a number of the older kinds are doing well, and, what is of importance, they are holding their own in competition for popular favour with a large proportion of the newer kinds. That the early-flowering Chrysanthemums are likely to become extremely popular as plants for the hardy flower garden those who have given the question close attention for years unhesitatingly proclaim, and interesting events such as the one under notice are most likely to give the plants the notoriety they deserve than any other less prominent means. The "feast" will give those attending it the opportunity of making comparisons, and, as the date may be regarded as a very suitable period in the flowering season, good results must, as a consequence, follow. Mr. Sydeham has quite a number of the older Pompoms, which many of us have long since discarded, and, strictly to say, there are among them many plants with ideal characteristics for outdoor display. This event will be looked upon as an excellent trial of both old and new sorts, as the collection has been brought up-to-date by the acquisition of all new kinds which the different trade specialists and others have brought into commerce. On the Saturday in question, all who are interested in making known the excellent qualities of the early-flowering Chrysanthemums for all purposes will be welcomed to see the display. Added interest will be given to the meeting, as some four silver cups and other prizes will be competed for. Special classes have been framed for competition, and these are of such a character that both large and small growers will have an opportunity of competing on grounds of equality. The success of the display of early-flowering Chrysanthemums which took place in the Town Hall, Tamworth, last year, gives grounds for the promoters of the "feast" to hope for an equally pleasurable and profitable meeting of enthusiasts.—W. V. T.

Anemone Pompon Chrysanthemums.—There is no doubt that the age has abnormally large blossoms has done much to eliminate small sorts of Chrysanthemums from places where they were once grown, hence the reason why we find the Anemone Pompoms so seldom met with; but if they do not compare with Japanese and incurved in size, they are very beautiful, and so many of them being of dwarf habit are particularly adapted for growing in small houses. A few worth noting are Ernest Carr, crushed strawberry; Grace Darling, lilac-blush; Mue. Sentir, white; Eugene Lanjaulet, yellow; Eric, orange-buff; Meteor, crimson and gold; Perle, deep rose; and Calliope, ruby-red.—W. F. D.

TREES AND SHRUBS.

THE MOCK ORANGES (PHILADELPHUS).

All the Mock Oranges, with the exception of *P. mexicanus*, which is tender, are quite hardy, and from their great beauty deserve far more attention. They are generally seen in some choked-up shrubby border, and often in some shady spot where they bloom but sparingly. Ample space should be allowed for the free access of air and sunshine, as upon this will to a very great extent depend the future display of bloom. The larger kinds are seen to great advantage when isolated on the Grass or disposed thereon in a group of three or four, plenty of room being allowed each for its full development. Complaints are often heard of some of the Mock Oranges failing to flower in their usual profuse fashion. This is, doubtless, often owing to their growing too freely, as where the soil is rich and moist they will not bloom so well as if it is drier and less rich. In pruning the Philadelphia, if carried out at all, the main thing should be to remove exhausted and useless wood.

P. coronarius is the common European Mock Orange, which is so well known that any further description is unnecessary. There are, however, one or two well-marked varieties, as well as several with double blossoms.

P. Gordonianus, belonging to the large-growing kinds, is a native of North America. The blooms are smaller than those of the last named, but produced in the greatest profusion.

species a good deal in the same way are *P. inodorus* and *P. verrucosus*, both North American, while *P. mexicanus* is too tender to be generally planted.

P. grandiflorus (syn. *P. speciosus*).—This is certainly one of the finest flowering shrubs

P. hirsutus.—In this the flowers are, with the exception of those of *P. microphyllus*, about the smallest of the genus. They are also generally solitary, but are borne in great profusion, so that a specimen is wonderfully pretty when in bloom. This, as a rule, grows about 4 feet or 5 feet high. *P. Lewisii* is a good deal in the way of this last.

P. Lemoinei, said to be the result of a cross between *P. microphyllus* and the European *P. coronarius*, forms a shrub in general appearance about midway between its parents, and flowers very freely. The blossoms possess the pleasing fragrance of its North American parent, without any of the heavy smell common to the Mock Orange. Since *P. Lemoinei* was sent out, a second form has made its appearance from the same source under the name of

P. Lemoinei erectus. Though of more erect habit, this is in other respects much like the preceding.

P. microphyllus forms a dense bush, at the most not more than a yard, and frequently less, in height, clothed with small Myrtle-like leaves, disposed in a regular manner on the slender twigs, which in their turn are arranged regularly. The fragrance of the flowers is very pleasant, being more like a combination of ripe Apples and Quince. This kind is a native of New Mexico and some of the adjacent States, and was introduced in 1853, but it is now far from common.

P. SATZUMI.—A slender yet freely branching bush about 6 feet high. The flowers, though

Philadelphus microphyllus.

to be met with in gardens. The individual blooms are a couple of inches in diameter, pure white, and with comparatively little scent. This forms a rounded mass from 6 feet to 12 feet

Philadelphus grandiflorus. From a photograph by G. A. Champlin.

They are also later in opening than these of most of the others, and on that account this species is especially valuable. It was introduced from north-west America in 1823. Other

in height, according to the soil and situation in which it is growing. There is a variety of this (*P. g. laxus*) less in stature and of a more open style of growth than the type.

rather small, are borne in little clusters for some distance along the shoots. Forms of this are often met with under different names, and it is also very probable that the North Ameri-

can species could be reduced in number if grown under similar conditions and compared together.

FRUIT.

LIFTING PEACH-TREES.

EARLY lifting of trees is not favoured by some, but it is useless to wait for the leaves to fall if the best results are expected next season. No matter how carefully one plants Peach or Nectarine trees, with good culture gross wood results, and this grossness is better counteracted by lifting than any other plan—that is, if due attention is paid to extension. In good loam the trees invariably run to wood, and as one is anxious to fill a large space as early as possible, a check during the growth of the trees is not given by stopping. In such cases lifting may be described as the remedy. By proceeding cautiously there need be no fear as to loss of crop, and the health of the tree will be assured for the next four or five years. If care is taken to preserve the fibrous roots no harm will follow. Cherries thrive much better the following season if lifted or planted early in October in ordinary seasons. This early lifting or transplanting is more difficult when the trees have to be conveyed some distance, but even then it is advisable to plant early, provided the trees are well furnished with fibrous roots. In lifting, care should be taken to keep at a good distance from the trees, and in the case of Peach trees in early houses lifting should be done early in September. It is a very good plan to dump the lifted trees overhead in the evening, as this keeps the buds plump and enables forcing to be done more readily the next season. With large trees it is not necessary to remove every particle of soil. Allow that adhering to the fibrous roots to remain, provided the weight does not break the latter. The preservation of fibrous roots is an easy matter if room is allowed at the start to get round them. All large roots may be cut clean off at a fair distance from the tree, and if the roots are inclined to descend, planting higher is beneficial. Manures of any kind should be omitted, good turfy loam well rammed or trodden being essential, and in clayey soil some mortar, brick rubble, or road scrapings is a valuable addition.

By this early lifting, severe cutting back, often the cause of canker later on, is avoided, and the trees can be forced the next season if not subjected to excessive night temperatures at the start. In the case of trees on open walls and that are required to fill up gaps early lifting is advisable, as by so doing the root action continues as long as the leaves remain, if these are assisted by frequent dampings to preserve vitality and encourage new root growth. After lifting no tying should be done till the trees have well settled down.

NOTES AND REPLIES.

Treatment of Raspberries (E. L. S.).—You may cut away the old fruiting canes on your Raspberry-stools at once. In future, cut them away as soon as they have done fruiting, as then more room is given for the young canes to grow and ripen. If your stools are a few feet apart in rows, the usual course is to allow about five stout canes or six weaker ones to remain for the following year's fruiting, cutting out all the rest. Do that now, also as many small canes or suckers, only do not injure those it is desired to save. When that is done, it is well, unless you can give the surface some manure, to allow the breadths to remain until the leaves have fallen, then to tie up the canes to stakes, rather loosely than tight, and to give the soil a dressing of manure or decayed garden-refuse, and only very lightly fork it in.

Pears as pyramids.—Will you please give me the names of the best twenty Pears to be grown as pyramids?—*BORIS, Worcester.*

[All of the following twenty varieties of Pears named, and placed in their order of ripening, succeed as pyramids. They bear freely, and should answer well in the district in which "Bobus" lives:—From July to end of September: 1, Colmar d'Été, 2, Clapp's Favourite, 3, Williams' Bon Chrétien, 4, Souvenir du Congrès, 5, Beurré d'Amansis. October to end of December: 6, Beurré Superfin,

7, Beurré Hardy, 8, Beurré Fouquieray, 9, Louise Bonne of Jersey, 10, Marie Louise, 11, Doyenné du Comice, 12, Seckle, 13, Hacon's Incomparable, 14, Conseiller de la Cour, 15, Thomson's, 16, Huxley's Prince of Wales. January to March: 17, Knight's Monarch, 18, Winter Nellis, 19, Bergamot Espereu, 20, President Barabe. As "Bobus" does not state the purpose for which he requires the Pears, we have given him a list of the best flavoured, irrespective of size. If he intends marketing the produce, he should substitute Pitmaston Duchess for No. 12, Durondeau for No. 15, Marie Louise d'Uccle for No. 16, and Josephine de Malines for No. 17. If a stewing Pear is required, Verulam or Black Pear of Worcester may be substituted for No. 20.]

Root-lifting and tree-moving.—As root action is brisker after the crops are cleared from the trees and the wood hardened, any root-lifting and tree-moving that may be thought desirable should be done, this giving the trees a chance to recover from the check before the leaves drop. Those trees that are rooting most strongly near the surface prove the most profitable, these also presenting the healthiest appearance throughout the season. Deep root action is very frequently denoted by the sickly yellow colour of the points of the branches. Now is a good time to open a wide, deep trench at a distance of 3 feet or rather less from the stem of the trees, following this up by well undermining so as to reach all the deep running roots. In many instances it is necessary to considerably raise the ball of soil and roots saved, the collar of the stem being brought fully up to or even well above the level of the border. In any case, the roots saved, after having their broken ends pruned, should be brought up much nearer the surface than heretofore, and if the old soil is at all exhausted, substitute a good loamy compost. Trees may also be safely transplanted from early houses to successional compartments, or *vice versa*. No attempt should be made to save a very large ball of soil with the roots, especially if hot-water pipes are in awkward positions or doorways have to be passed through. Take good care of the best of the roots, and make some allowance for sinking when the trees are replanted. Keep the roots within easy distance of the surface, and well distribute them through the soil. Keep the old ball of soil constantly moist, but avoid saturating the new soil. Syringe all newly-moved trees frequently; they must be kept constantly wet, in fact, if disposed to flag badly, and they should also be shaded from bright sunshine and kept rather close. Partially lifted trees that give signs of flagging should be similarly treated.

BOOKS.

THE "BOOK OF THE STRAWBERRY."

OUR readers will, we think, agree with us that Dr. Harry Roberts was well advised in delegating the writing of the ninth vol. of the series of handbooks he is issuing, entitled the "Book of the Strawberry," to Mr. Edwin Beckett, head gardener to Lord Aldenham, Aldenham House, Elstree, for we consider it one of, if not the most valuable of the series yet issued. Mr. Beckett is, as so many of our readers are already aware, a well-known and highly successful gardener; he is also a liberal contributor to the gardening press. The treatise contains eighty pages, fifty of which are devoted exclusively to the Strawberry, the remainder being given up to the consideration of the culture of Raspberries, Blackberries, and the less known Japanese Wineberry and Loganberry. The chief portion of the work, therefore, is, as it should be, given up to Strawberries, and the various details in connection with their successful culture are all treated upon in a concise yet thoroughly lucid manner, and under different headings. The advice tendered in every case is sound, practical, and to the point, whether it be respecting the selection of sites, preparation of soil, propagation, manuring, or the forcing of the Strawberry, so that all who read may readily understand what the writer intends to convey.

* "The Book of the Strawberry," by Edwin Beckett. Edited by Dr. Harry Roberts. John Lane, The Bodley Head, London and New York.

The grower for market is not forgotten, as the production of Strawberries on a large scale is treated upon, as are also the best known methods of packing and despatching the fruit when gathered. So pleased are we with the treatise that, irrespective of the portion devoted to Raspberry and Blackberry culture, which is exceedingly good, we have not the slightest hesitation in recommending it most highly to the notice of all amateurs who wish to excel in the cultivation of the Strawberry, while all practical gardeners should add it to their bookshelves for future reference. The volume is uniform in size and binding with its predecessors, and is printed and published by John Lane, The Bodley Head, London and New York.

GARDEN WORK.

Conservatory.—Among the easily-grown but useful plants in many conservatories now, we may mention *Humea elegans* and the *Chimney Campanula*. The *Humea* is useful outside, and so also is the *Campanula*; both are biennials, and may be raised from seed in spring. If the sowing is delayed beyond May, the plants hardly get size enough to flower freely the following year. Tree-Carnations will be better under cover now or in some position where they can be sheltered from heavy rains. They should be neatly supported with small stakes, and the plants which have filled the pots with roots may have weak root-water occasionally. We find this very good for Carnations in keeping the plants healthy and vigorous. An easy way of working up a stock is to plunge out the old plants after flowering in May or early in June, and layer the young shoots. Of course, a stock can be worked up from cuttings, but I think layers are best. Soot-water is a good stimulant for many things, but especially *Camellias*, from this onwards. These plants will be under cover now, but the houses should not be altogether closed either night or day. If the flower-buds are very numerous they should be thinned now, leaving the best-placed buds only. It is reported the *Azaleas* in Belgium are not likely to be so large this season in consequence of the unfavourable weather, and where such things as *Solanums*, *Arum Lilies*, and *Bouvardias* are planted out, the plants are very backward. We usually plant out a part of our stock of *Solanums*, and grow the others in pots. Usually this plan answers well, as the two sets of plants form a good succession. Those in pots are now full of berries, but those planted have not made so much progress. The same condition may be noticed in other things planted out, everything being so backward, and not much chance now of fetching up the leeway. Those who are growing early-flowering *Chrysanthemums* in pots will find them very useful for grouping in the conservatory. As soon as a plant shows colour they should be housed in a cool structure, freely ventilated night and day. Less night ventilation may be given to the conservatory now, but the house must not be altogether closed.

Stove.—The fires must now be regular and steady, and this will necessitate careful watering. In hot weather in summer it is not easy to give plants which have filled their pots with roots too much water, but with longer night and less sunshine during the day it is quite possible to overwater even established plants, and newly-potted stuff must be carefully managed. The intervals between the applications will be longer, but whenever a plant requires water, enough should be given to thoroughly moisten all the soil. This is as necessary now as in hot summer weather. There are certain plants which have pretty well finished their work, such as the summer-flowering *climbers*, *Allamandas*, etc., and, among foliage plants, *Caladiums* should have water less frequently, so that they may gradually go to rest. In a mixed collection some things are going to rest and others are just commencing their work. Among the latter are *Poinsettias*, *Euphorbias*, and the fibrous-rooted *Begonias*, and these, of course, must have warmth and moisture to bring their flowers out to perfection. *Gardenias*, also, will stand all the warmth likely to be present in winter to bring the flowers out quickly. There should be no shade now, and

if Summer Cloud or other shading matter of a more or less permanent nature has been put on the glass, it should now be cleared off, so that the glass may be bright and clean. Night temperature now for mixed collections, 60 degs. to 65 degs.; for Ixoras and other heat-loving plants 5 degs. more may be allowed. But with high temperatures a close watch must be kept for insects, especially thrips and aphids, and the vaporiser used.

Winter Cucumbers.—This is a good time to plant a house for nutmn and winter bearing. There must be bottom-heat for winter, as root-warmth is quite as important as top-heat. After the new year Cucumbers may be started on a bed of warm manure that will carry them on for a couple of months or so; but this will not do in the short days. With a comfortable bottom-heat we do not care so much for a higher atmospheric warmth at night than 65 degs. Of course, 70 degs. will push things faster, but we generally find a high temperature tends to exhaustion. At first setting out Cucumbers do not require large mounds of soil; but what they do require are frequent top-dressings as soon as vigorous growth sets in. Winter Cucumbers are often planted in soil of too light a character. It is better to plant in rich old turf which has got some body in it, mixed with a little soot. Of course, wireworms must be exterminated, and if there is the least suspicion, a few Carrots may be buried just under the surface to attract the insects; and wireworms are specially fond of dwarf Kidney or French Beans. These form good baits for them, and should be placed in little heaps and examined occasionally. Where the demand for Cucumbers is a limited one, work on the principle of air giving when the thermometer rises to 80 degs. or 85 degs., but close early; but where many Cucumbers are wanted in a given time, and another house can be planted in succession, then give no air beyond what comes in through the laps, and use more moisture in the atmosphere. One of the best Cucumbers for winter is a good selection of Telegraph. The old original Telegraph, as sent out by the Messrs. Rollisson, was not quite like many of the Cucumbers under that name now. Lockie's Perfection is a very free bearer, and has a good constitution. Emerald Beauty, another of the Telegraph crosses, is one of the freest-bearing Cucumbers I know.

Tomatoes for winter.—If a few sturdy plants of Comet or any other good early kind are placed in 9-inch pots now and brought on quickly, there may be a few fruits in winter, but no one can make Tomatoes in winter pay. I have generally got Tomatoes through the winter by taking a second crop from the plants which have been bearing through the summer. There is no difficulty about this if the plants are healthy. Plenty of young shoots are breaking away now up the stems. As the fruits are gathered upwards the young shoots are stopped at the first truss and tied in.

Window gardening.—It is getting late enough to take cuttings, though they will strike if care is used. Keep the cuttings outside for the present, but always be prepared to cover with something on the approach of frost. If anything among Palms or other foliage plants requires potting, see to it at once. Give only a small shift, and see that the drainage is right. Pelargoniums that were cut down in July will be ready for shaking out and repotting. The loam must be of good quality.

Outdoor garden.—The sooner early-flowering bulbs are planted now the better. The majority, of course, will not be planted till after the beds are cleared in October, but that does not prove that September planting for Narcissus, Crocus, and Snowdrops is not the best. Early-flowering Tulips may also be planted as soon as convenient, but Lord Mayor's Day, 9th of November, was the usual date of planting of the old-fashioned florist. September is a good month for sowing Grass-seeds on new lawns. Seeds sown now will germinate immediately. Thoroughly dig and manure the land if poor, then make it perfectly level and roll down firm when the surface is dry. After rolling, if there is any fault in the levelling it will be easily seen and must be put right, and then rolled again. Sow the seeds on perfectly level and firm surface. Do not strew the seeds, and obtain them from the best

source. After sowing scatter some fine rich compost over them and roll down again, and if the birds are numerous run strands of bleck cotton over the lawn about a foot or so from the ground. Vacant spaces in borders may be filled now with Wallflowers, Sweet Williams, Canterbury Bells, and other hardy plants. Seeds also of hardy annuals may yet be sown.

Fruit garden.—To colour Muscat Grapes well requires warmth and strong light, and, though none of the old leaves should be removed, all the sub-laterals should be shortened back. Fire-heat, too, will be necessary for late crops of both Muscats, Gros Colmans, and Lady Downes. Alicante will generally put on colour without artificial heat, but a little warmth in the pipes in a season like the present will be beneficial. Early Apples and Pears should not be permitted to fall from the trees. If not already done, the fruit-room should be thoroughly cleansed with soap and hot water. In most places this is done earlier in the season. The land works well now for Strawberry planting. Royal Sovereign is one of the best Strawberries, both for forcing and planting outside. It has a strong constitution, and may be grown where other kinds fail, and, though in low situations a few of the blossoms may be cut off in spring, the fruits which survive always come large. One of the best traits in the character of this kind is that it swells up its late fruit. Look over wall trees and remove all late growth, and train in all leading shoots. Remove the mulch from Apricots and Peaches, and let the sun warm the borders.

Vegetable garden.—Continue to make up Mushroom-beds under cover to follow each other in succession, as Mushrooms in autumn and winter are always useful. Thin the foliage of Tomatoes in cool-houses to hasten the ripening of the late fruit, especially when the houses are required for other purposes. The defoliation need not be carried too far, but merely thinned to let in the sunshine. Onions spring-sown are later than usual in ripening; but get them ripened and harvested as soon as possible. Give the land a dressing of soot, and hoe it up deeply ready for planting Cabbages by spring. Where the land was well done for the Onions the deep hoeing will generally be sufficient for Cabbages, as they will heat sooner when the land has not been much disturbed to any depth. Get the late-sown Turnips well thinned; let each plant have not less than from 12 to 15 inches of space, so that the leaves may be on or near the ground to afford protection when frost and snow come. These late-sown Turnips will come in for the spring supply. Continue to earth up Celery in dry weather. Plant a few dwarf Kidney Beans in a pit where heat can be given when required. Ne Plus Ultra is a good variety. Scarlet and other Runners are bearing freely now; gather all pods when fit for use, and preserve in jars for winter use.

E. HOBDAV.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 15th.—Most of the early Potatoes have been harvested, and those intended for seed selected and placed in cool shed, to be afterwards stored in shallow trays or boxes in a frost-proof store. Potted more bulbs for early forcing, including Narcissus, Hyacinthus, Tulips, and a few pots of Crocuses and Snowdrops. The latter will not force well, but they flower so early, when potted in good time, that forcing is unnecessary.

September 16th.—The large Palms and other plants that were plunged out at the end of June in sheltered spots about the grounds have now been placed in the houses none the worse for their outing. Many things, including Oranges and Oleanders, are generally improved by a summer in the open air when their wants are attended to; but the middle of September is late enough to keep them out. Frosts may be expected any time, and tender things we wish to save will either be potted up or covered with tiffany on cold nights.

September 17th.—Chrysanthemums are watched from day to day, and any plants with buds in a forward state are placed under cover in a well ventilated house. Stimulants are

given in a weak state frequently now. We have not seen any rust on our plants this season yet. A good batch of Primula obconica grandiflora is now coming into bloom in 5-inch pots. We find these make a charming group during winter. The plant has been given a bad name, but we have felt no inconvenience from it.

September 18th.—All snrplns growth has been removed from Tomatoes, both indoors and outside, to induce the fruit to ripen. Early Apples and Pears are gathered as soon as they part easily from the stalk. Jarponello Pears on standards are later than usual this season. The same may be said of Williams' Bou Chrétien. Both kinds are bearing freely on pyramids and standards. Apple beauty of Bath has never borne a good crop yet, though we have it several years planted.

September 19th.—The early seedling Cyclamens are now showing flowers, and both flowers and foliage are strong and sturdy, and the plants will now be taken to a light house, but no fire will be used yet. Cold-pits are getting too damp for these plants now. Primulas will be placed on shelves near the glass in a light house, but fires will not be used till absolutely necessary. Prepared a bed for cuttings of Roses. We find the cuttings strike best in sandy loam. Will be mulched later with leaf-mould.

September 20th.—Planted Cabbages for sprig, chiefly early kinds. Part of a south border has been planted more thickly than the main crop, which comes in later. Very early Cabbages when young and tender are sought after, and we find it advisable to give up part of a south wall border to them, and plant about a foot apart each way. When the hearts are cut the stems are pulled up and the land prepared for another crop. Gathered seed-pods of a choice strain of Petunias.

POULTRY.

Guinea-hen ailing (G. W.).—Your Guinea-hen appears to be suffering from liver disease, brought about, in all probability, by too high feeding. Avoid all stimulating and heating kinds of food, and give one grain of calomel every other day for a week or ten days, mixed with the soft food. Also lessen the quantity of food given at each meal, and for a time do not give the bird quite as much as it can eat. If for a few days only just enough food were allowed to keep it alive, benefit would arise, as this would allow the digestive organs time to recoup their strength. After the course of medicine has been gone through, add a little sulphate of iron to the drinking water to give strength and stamina. Boiled Oatmeal is very good in a case of this kind, while a crumbly paste, made by mixing boiled vegetables with Barley-meal, is good at any time. These birds require a wide range, where they can be constantly on the move, and pick up insects and other natural food on their travels; otherwise, they cannot remain long in good health.—S. S. G.

BIRDS.

Parrot pulling out its feathers (Constant Reader).—Your bird appears to be suffering from an irritable condition of the skin, which would cause it to peck itself and draw out its feathers. This irritability of the skin would arise from various causes, being sometimes associated with indigestion through improper feeding, the presence of insects in the cage, or through the bird having been kept in a dry, over-heated temperature. Parrots should not have animal food in any form; you must, therefore, discontinue the butter. In addition to the boiled Maize, you may supply Canary-seed, Hemp, and a few Oats, together with some ripe fruit, as Grapes, Bananas, Pears, Nuts (with the exception of Almonds and Walnuts), may be added to the bill of fare. For medicine give a little carbonate of soda, putting 5 grains in two tablespoonfuls of drinking water. Do not fail to supply your bird with a good allowance of coarse grit sand to aid the pizzard in the digestion of the food. A piece of soft, non-splintering wood should be provided for which your parrot could exercise its powerful beak, and the occupation afforded

thereby would tend to divert its attention from the feather plucking habit. If there is any indication of the presence of parasites in the cage, paint it freely with paraffin after well scalding.—S. S. G.

LAW AND CUSTOM.

Lending money on mortgage.—I lent on mortgage £150 on a garden. After awhile the mortgagee leaves it on my hands, and it does not realise by sale more than £125. As the mortgagor has another field near, can I compel him to sell that field to make up the £25, or only be an ordinary creditor?—Devon.

[Most mortgage deeds contain provision making the borrower personally liable in such cases. But you cannot seize the other field or make him sell it. Your course is to sue him for the balance, and you had best consult the solicitor who acted for you in the mortgages.]

A market gardener's position.—In March, 1887, I took a garden belonging to a private house on a seven years' lease, at an annual rental. When the lease expired by effluxion of time, I could not get another lease, as the owner was getting old, so had to take it on a yearly tenancy, on a verbal agreement, at the same rent as before. In 1891 the owner died, and the land had to be sold, and the new landlord let me remain at the same rent as I had been paying. Last March he sent me a notice, to expire next March, saying that he was going to sell the land before my term was up; he has done so, and the new landlord wants me out as soon as he can get me, so how do I stand for compensation? Can he compel me to go before March 19th, when the year of tenancy ends, without paying me? I have built and heated greenhouses on the land, potting sheds, stable, fowl-houses, and runs, and have got the ground planted with trees, shrubs, annual and perennial plants, fruit-trees, etc. I have got Vines planted in the houses, and Roses, as well as the usual pot plants, and a portion of the land is matured ready for shrubs again. If I remain to the end of my tenancy can I claim anything, as it will cost a good deal to move the houses, etc.? Beside, they will hardly pay to put up again.—Kex.

[It is probable that the Market Gardeners' Compensation Act applies. It will apply if, previous to January 1, 1896, you had planted and permanently set out any fruit-trees or fruit-bushes, or any Strawberry-beds, or any Asparagus or similar vegetable crop, or erected or enlarged any buildings for the purposes of your trade or business as a market gardener, and your landlord was, previous to January 1, 1896, aware that you had executed the improvement in question. If such was the case—that is, if you had executed one or more of these improvements and the landlord knew of it—the act applies to your holding, and you may claim compensation for any of the improvements executed since Dec. 31, 1895, but not for improvements executed previously. Your claim will be for the value of the improvement to an incoming tenant of the holding, and must be made upon the landlord not later than March 13, the last day of your tenancy. You may claim compensation for the greenhouses, potting-sheds, and fruit-trees and fruit-bushes, also for the stable, if the stable was really erected for the working of the business of a market gardener there. You cannot claim for the fowl-houses and runs, nor for any flowers, flowering shrubs, etc., although you may remove all such as were planted for sale and not for the sale of their produce. If, however, for the reasons indicated, the Market Gardeners' Act does not apply to the holding, you may, on giving a calendar month's previous notice in writing to the landlord, remove before your tenancy expires all the buildings and fixings erected by you, but none of the fruit-trees permanently set out, nor can any flowers, shrubs, etc., be removed. The reason why these erections can be removed is because, no matter whether the Market Gardeners' Act does or does not apply, the Agricultural Holdings Acts do apply. The question has so far been answered on the assumption that you will remain in occupation until March 19 next. Your landlord (who, I expect, is the purchaser) cannot compel you to leave before March 19, and if he wants you to go sooner he must buy you out, and you can insist upon any terms you choose, and refuse to go if your terms are not accepted. But you must take care that you have a definite contract in writing, stamped with a sixpenny stamp, and your best plan will be to have the whole matter settled before you give up possession, and to make it a part of the agreement that you shall give up possession when payment of your compensation is finally made.—K. C. T.]

CORRESPONDENCE.

Questions.—Queries and answers are inserted in GARDENING free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of GARDENING, 17, Furnival Street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as GARDENING has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages and sizes of the same kind greatly assist our determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being unripe and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Gamma-moth (C. W. D.).—The eggs on your Orinus are certainly those of a moth, and were laid by the common or Gamma-moth, or some nearly allied species. They are very beautiful objects under a microscope.—G. S. S.

Oil heating apparatus (Subscriber).—There are several different forms of oil heating apparatus advertised in the columns of GARDENING ILLUSTRATED, all of which are doubtless good. We cannot compare the merits of one kind with those of others.

Pentstemon (P. M.).—The seedling Pentstemon should have been transplanted. They are growing too freely. Cuttings of these beautiful autumn flowering plants are better than seedlings—at least, they blossom more freely. If you procure some of the best named sorts you can propagate your own by inserting a few cuttings each autumn under a cloche.

Roses against a wall (F. J.).—Your wall is not high enough for such a strong-growing Rose as *Blonde de Dijon*. A height of 20 feet suits it better. Instead of cutting back the strong shoots now, cannot you bring them down in a more horizontal direction? They will then flower more freely every year along the branch. If you cannot do this you must cut off the tops down to the height of the wall.

Hollyhocks—should lower leaves be removed? (Charlie Cubley).—We should advise you not to interfere with the natural growth of your Hollyhocks. Their habit is at all times both stately and beautiful, and to denude the plants of their lower leaves is to spoil their good effect in the garden. It is quite natural for the plants to flower at the bottom first, but if you will be careful to observe you will see that the blossoms develop in proper sequence right from the bottom of the plant to its apex.

Rose Beryl (Tea scented) (F. R.).—In the bud state there is no golden-yellow Rose more beautiful than the above. The buds are very long, produced freely on extremely slender shoots. The flowers are almost single when open, and are rather uninteresting, but the buds amply make amends for this. One cannot look upon this Rose without wishing it were a little larger and more full. There is a very refreshing fragrance also belonging to the variety. We can commend the Rose to all who appreciate beautiful buds, and, as the latter are so liberally produced, it would make a very useful garden Rose until we get something better.

Rose-rust fungus (Mrs. Broomhead).—Your Roses are attacked by a common fungus known as the "Rose-rust" (*Pragmidium sub-torturatum*). You should collect and burn all the infested leaves in the autumn, or as they fall. In the early spring, before the buds expand, very thoroughly wet all the shoots with the following solution: 2 oz. of sulphate of copper dissolved in 3 gallons of water. It would be as well to spray the soil round the plants with the same mixture. If the disease still shows itself, as soon as it is noticed spray the bushes with dilute "Bordeaux mixture." The light soil would not cause the disease, but anything that in any way causes the bushes not to grow as vigorously as they should renders the plant more liable to attacks by fungi and insects, and a light soil is not so suitable for Roses as a heavy one.—G. S. S.

Growing flowers for market (Madge).—You want to know whether you can make an inderete income from the cultivation of flowers for the early market in a large sheltered garden. Your question is as vague as it is possible to make it, and it is impossible to give any definite reply to it. First of all, what is the area of the "large sheltered garden?" Why not have stated it? Then what do you consider a "moderate income?" For all we know to the contrary, you may be one who would consider a pound a week affluence, or, on the other hand, you may consider your labour ill-repaid if rewarded with a couple of hundred a year. Further, you may say a word as to your knowledge of gardening, your business training, or give us any information on which to base an opinion as to your chances. All we can say is that some good gardeners with business aptitude can make a reasonable profit from such work, but there is much competition nowadays, and prices obtained are often disappointing.

Plants for pool-side (D.).—You would find London Pride (*Saxifraga umbrosa*) excellent for growing among the stones overhanging the water. It gives a beautiful effect when in blossom, and is never unattractive. The common *Mimulus*, yellow and red, would also grow in great luxuriance, and only needs to be kept in check. The Water Forget-me-not (*Myosotis palustris*) is a beautiful water-side perennial. The three plants mentioned will grow and flower year after year by the water, and the trailing *Mitella* complexa may be planted to hang over the bank. The large-flowered *Saxifraga* will also

flowers well in positions overhanging the water, and the bright scarlet *Mimulus cardinalis* is a very distinct effect. As for a flowering plant to grow in the centre of the pool, one or two of Marjorie's Water Lilies might be planted. The only other "free-flowering plant" that might succeed in 2 feet or 3 feet of water would be the Arum Lily (*Richardia thibetica*), but this will live only in the most favoured spots in England out-of-doors. See article on "A Yorkshire Water Garden," on page 347, August 30.

Roses for east and west aspects (Rose).—"Haeley," free-growing, with close flowers and fragrance, are conditions that considerably limit the selection. Although the collection of Tea and Hybrid Tea Roses now cultivated is exceedingly numerous, there are but few which one can term "fragrant." We take it for granted you mean Roses of the La France type. For such one must select from the Hybrid Perpetuals. There are a few Tea nearly as sweet, but then they are not quite hard, and there that are fairly hard and sweet are not what you term "close flowers." We think the following six kinds would be best for the eastern border—Standards: Prince C. de Rohan, Senateur Vaisse, Mrs. John Laing. Bushes: Caroline Testout, Fisher Holmes, Gladly Harriet. And for west border—Standards: La France, Earl of Dufferin, W. A. Richardson. Bushes: Mme. Abel Chateau, Liberty, Mme. Jules Grozet. Good yellow and apricot coloured Roses are: Mme. Charles, Mme. Moreau, Billard and Barre, Bouquet d'Or, Belle Lyonaise, Alliance Franco-Busse, Souvenir de Wm. Robinson.

Roses for various purposes (E. M. E. F.).—Of the flats you submit, the majority of them will succeed well either as standards, dwarf or seedling Brier, or on own roots. The kinds which will make the best standards are Marie Van Houthe, Anna Olivier, La France, White Maman Cochet, Mme. Falcot, Mme. Berard, Caroline Testout, L'Idéal, Viscountess Folkestone, Gloire Lyonaise, Mrs. John Laing, and Prince C. de Rohan. If you desired any of these to be raised from your own plants rather on the Brier or own roots; the latter preferred if the plants are strong. The other thirteen varieties would be strongest plants on the seedling Brier, as you could doubtless procure some of them on their own roots. As your list consists mainly of Teas and Hybrid Teas, and as these are usually only procurable, as our roots, in pots, we should advise you to obtain dwarfs on the seedling Brier, unless you care to plant own roots immediately or late next spring. Mme. Berard and L'Idéal are considered climbers, but they make grand spreading heads on standards.

Tuberous-rooted Begonias (A. T. M. F.).—If the tubers are large, Begonias can be readily increased by division into as many pieces as there are separate stems. To succeed in this the tubers should at the proper season be placed under conditions favourable to growth, and as soon as the young stems are from 1 inch to 2 inches high take a sharp knife and divide the tubers according to the shape of the plants, taking care to leave a good quantity of tuber to each stem. Then repeat in the ordinary way, keeping the piece of tuber at the base of the young shoot well below the surface of the soil, and treat just as growing tubers that have not been thus operated upon. Tuberous Begonias may also be increased by cuttings of the shoots first pushed up in the spring, which should be cut off at a joint, put into small pots of light sandy soil, and placed in a close propagating case till rooted. In taking these cuttings leave one good eye remaining on the old plant, in order to allow a shoot to be produced therefrom.

Chrysanthemums—when to lift plants for flowering indoors (Charlie Cubley).—The fifteen varieties in your collection embrace some of the very best large Japanese flowers, and on this account they should be disallowed. In reply to your question as to when the plants should be lifted from the open ground and potted up, no given date can be laid down for operation to be carried out. A good rule for you to follow will be to place the respective plants in their flowering pots when the buds of each one are nearly developed. As a preliminary to this operation, we advise you to ease the soil on one side of the plant on one day, and after the lapse of a day or two to observe the same rule on the other side. In this way the plants may be potted up with less ill effects than would otherwise be the case. Should the weather be warm at the time of potting up, stand the plants in a cool position until they are recovered from the shock of being lifted from the open ground, and soaked with clear water. After a time, and when there are prospects of a frost, remove the plants indoors.

Plants for bazaar in February (Ladybird).—There are none of the showy summer annuals at all likely to prove satisfactory under the conditions you name, and to obtain flowering plants for next February you will be compelled to fall back on bulbs such as *Hyalocallis*, Tulips, Narcissus, *Scilla sibirica*, *Chionodoxa Lucilia*, Snowdrops, etc. All the bulbs should be potted by the middle of October, placed out-of-doors, given a good watering, and covered with Cocoa-nut refuse and coal-ashes for a month or six weeks before taking them into the greenhouse. By this treatment plenty of roots will be pushed out, a very important matter whenever bulbs are to be forced, however slightly. In this way they should be ready at about the time you need them, but the vagaries of our climate must also be taken into consideration, so that it may be necessary to remove some to the cooler and other to the warmer end of the structure, but that must be left to your own discrimination when the new year sets in.

Roses on north-east coast (A. W.).—I, Yes, Mme. Perle Ducher will be sure to thrive with you. Its blossoms are not nearly so fine as those of Kaiserin Augusta Victoria, but the variety possesses a sturdier nature. When the right position and soil are found for K. A. Victoria, no Rose is more beautiful. It seems to require a warm, perfectly drained soil, and the bed sheltered from north and east. 2. We place the five Roses in order of merit as follows: Mme. Falcot, Mme. Guinoisseau, Medea, Beauté Inconsciente, and Berli. We should prefer Mme. Charles to Mme. Beauté Inconsciente and Souvenir de Catherine Guillot instead of Berli. 3. Yes, Beryl is a lovely bud, but we consider it overrated. Mrs. Perle Ducher, Belle Lyonaise, and William Robinson, or George Schwartz, Comtesse Festiva Hamilton is superior to the other, but not quite such a good

grower. There is not sufficient difference in growth to give General Schablikino the preference. We have a very high opinion of Comtesse Festetics, and believe it will be largely grown.

Teas and Hybrid Teas for Scotland (Tea Major).—You would find the twelve undermentioned Tea Roses would thrive well in your district, supposing you well prepare the soil for them by digging deeply and providing ample drainage for the beds: Mme. Laingard, Mme. Falot, Mme. Hoste, Maman Cochet, White Maman Cochet, Marie Van Houtte, Marie d'Orleans, Encantement, G. W. Robinson, Souvenir de S. A. Prince, Souvenir de Wm. Robinson, Mrs. Edward Mawley. And the following twelve Hybrid Teas always give satisfaction and grow well: La France, Caroline Testout, Mrs. W. J. Grant, Yvonne, Mme. Abel Chatenay, Mme. Pernet Ducher, Chiffonney, Mme. Jules Grolez, Gruss an Tepitz, Clara Watson, Viscountess Folkestone, Billiard and Barré. If you are careful to well earth up the plants from November to April you will have no difficulty in getting them through the winter. The soil used to mould up with should be free from large lumps. Burnt earth is equally as useful as ordinary earth. Cover the base of the plants for 6 inches with one of these materials.

FRUIT.

Planting Peach-trees in a house (John W.).—In a house but 25 feet long you can plant only two flat-topped Peach-trees. When they do well they fill such a space in a few years. You must, of course, plant inside the house; but it will not do to plant in a border, with trees beneath, as the dry heat from those would do great harm to the roots. You must have a border fully 4 feet wide and 2 feet deep. In the bottom should be a little rough material to make drainage, on that turves, Grass weeds, and then filled up with good burly loam one inch, good garden soil one half, with some old mortar which, riddled, and fine crushed bone, well mixed. The border should be trodden firm before you plant, and then in it to fresh animal manure. Plant shallow, and as early in October as you can. You should ask for trees on pot stems, to bring them up to the eaves. After planting them, then place a layer of manure thinly over the soil. Let the border settle well before you begin to water the branches.

Making fruit-rooms (Lindens).—The description of a room suitable for the winter storing of Apples and Pears, in which the air should be a little humid, will not do for Grapes. These when cut, and the long wood stems with them, are inserted into bottles nearly filled with water, the bottles being stood on racks so that the mouths of the bottles hang downwards, from which the bunches of Grapes will hang; they must be in a dry air, where on dry days ample ventilation can be given. An Apple and Pear store should be built on a level, with a walk of brick or concrete to exclude frost, and a roof of straw or reed that will exclude cold and warmth also. The temperature should be very equable, and range from 40 degs. to 50 degs. Such a shed built on a gravel base or where it is well drained may be 10 feet wide, be either lean-to or gable-roof, have a centre alley 2 feet wide, and three or four rows of open trellis wood shelves on each side, and double doors at each end. If partly shaded by trees, so much the better. Let it run north by south.

SHORT REPLIES.

Mr. P. Abraham.—We cannot insert queries of this kind. The replies will of necessity be advertisements. — **Mr. E.**—The plant is probably *Magnolia grandiflora*, a tree requiring years before flowering well. We use the word "freely," and in lieu of "freely," as the frequency of this species is a rarity in this country. In a "south aspect" the wood should get well ripened each year, and for the rest it is merely a question of waiting for the tree to flower; the plant produces—huge creamy white flowers 6 or 8 inches across, and highly fragrant. The best of the rooting area of the plant is best open to the sun's influence, and not, as we often see it, crowded with such overhanging with coarse, shrub growth and like.

NAMES OF PLANTS AND FRUITS.

Any communications respecting plants or fruits to name should always accompany the parcel, and should be addressed to the EDITOR of GARDENING ILLUSTRATED, 17, FURNIVAL-STREET, HOLBORN, LONDON, E.C. The name should also be firmly affixed to each specimen of leaves or fruit sent for naming. No more than four names of fruits or flowers for naming should be sent at one time. — **Names of plants.**—*Philomathea*.—1, *Agrostis caudata*; 2, *Aira flexuosa*; 3, *Aira caespitosa* (Trifolium *sp.*).—**W. Apled.**—We do not undertake to name plants, as they are so numerous and in many cases resemble each other so closely that the habit of the plant and other features which are not shown in a small illustration require to be taken into consideration. We have, however, compared the *Fuchsias* sent with a large collection, and consider them to be as follows: 1, *Display*; 2, *Castile*; 3, *Phenomena*; 4, *Charming*.—**Mr. R.**—*Scilla cornuta*; small flower is *Galeopsis ladanum*.—**Mr. A. S.**—*Mimulus* or *Diplacis glutinosus*.—**Mr. J. S.**—*Meadow Sweet* (*Spiraea Ulmaria*).—**S. M.**—*Asclepias tuberosa*; 2, *Variegated Maple* (*Acer variegatum variegatum*).—**Marshall**.—1, *Sedum Sledboi*; 2, *Veronica salicifolia*.—**Tockington**.—Yes, *Campanula*, and, if you send a fine specimen with its own name, we may possibly name it. We may give you the name of height, etc.—**Frank Harvey**.—Large head *Hydrangea paniculata grandiflora*; the other is *Hydrangea grandiflora alba*. Specimens should always be accompanied for reference.—**L. C. M.**—Nos. 1 and 2, *Phlox*; 3, *Phlox*; 4, *Phlox*.—**Wm. Spickett**.—No, the *Fuchsias* have distinct points of difference; but we do not undertake to name florists' flowers, as this can only be done after careful comparison in a large collection. — **W. S.**—*Sedum album*.—**J. P. M.**—Scrap of leaf *Erigeron* for naming. A good *Erigeron* is *E. celestinum*. — **W. J.**—*Potentilla fruticosa*.—**Drunkilla**.—Specimens should always be in flower. 1, 2, and 3, We cannot name in form as sent; No. 4 may be *Mulinotheca*. — **Mr. A. C. Croydun**.—1, *Chrysanthemum*

coronarium; 2, Quite impossible. Dry cotton-wool is the worst thing in which to wrap such diminutive bits.— **Ayrshire**.—Large flower, apparently *Scabiosa caucasica*; Dark flower, *Linaria reticulata aurea-purpurea*.— **Miss King**.—1, *Veronica Andersoni*, probably (no flower remained when received); 2, *Rubus deliciosus*; 3, *Sedum oppositifolium*.—**Botanist**.—*Cistus ladaniferus*, or *Gum Cistus*.—**Chas. Good**.—Your delightful little coloured photograph was duly received, and the queries were answered in the number of GARDENING ILLUSTRATED for July 19, page 267. The name is *Hemanthus Katherinae*. It is a native of Natal, from which it was first sent to Kew in 1877. As the reply was a fairly lengthy one, we are unable to reproduce it, but must refer you to the page in question.

Names of fruits.—**W. J. Brown**.—We cannot name from single immature fruit.—**Deven**.—1, Devonshire Quarrenden; 2, Lord Sutherland; 3, Worcester Pearmain; 4, Hawthornden.

Photographs of Gardens, Plants, of Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1, Mr. Arthur A. Jones, 135, St. Stephen's Green, Dublin, for *Cordylino australis* in Penick's Delgany Nursery; 2, Mr. B. Phillips, Watverle, Olton, Warwick, for *Iberis sempervirens*.

Making Lavender water.—Can any reader kindly tell me the process of making lavender water sent from English grown lavender?—**SYDNEY HOAR**.

FRUIT.

FRUIT CROPS AND RAIN.

As everyone has been lamenting the continual downpour of rain, the fruit-trees have greatly benefited by it. If we had only a more genial night temperature in May and June, this would have been a record year for hardy fruits of all kinds, for where the seasons escaped the destructive frosts of May and continual low temperature until midsummer the fruits have swelled up a good size, although much later than usual. Even where a good crop is on the trees, they are extremely well budded for other years. This is solely owing to their being kept continually moist, both at the roots and on the foliage, for, as a rule, fruit-trees do not get nearly enough water at the roots, and one of the best things to repay a rickety grower, in order to get heavy and continuous crops of fruit, is an abundant water supply, so that he can run it on with a niggard hand. One of the fruits that I have noticed as being especially benefited by plenty of water, and the soonest to suffer in drought, is the Pear, and this has been an ideal season in every respect, except in regard to lack of warmth in the early part of summer. Even as it is, many of our trees, such as Williams' Bon Chrétien, Pitmaston Duchess, and Beurré d'Amanlis are loaded with exceptionally fine fruit, have made good growth, and are well set with bloom-buds for next year. Water enters so largely into the formation of fruit, it follows that any lack of it in the autumn when the fruit is swelling will result in small or malformed specimens.

JAMES GROOM.

NOTES AND REPLIES.

Mildew Grapes (M. F.).—Your grapes are undoubtedly badly infested with mildew. The attack is no doubt due to the cold, wet summer and, probably, exposing the vines to cold draughts of air. If the roots of the vine be outside, very likely they have had far too much moisture. If that be so, it would be well to cover the border at once with sheets of corrugated iron or boards to throw off the rains for a time—certainly until the leaves have fallen and the pruning is done. Burn all leaves and wood when cut off. Then your best course will be to make up a solution of soft soap, sulphur, and clay, and have the whole of the vine well painted over with it. The woodwork and glass should be scrubbed with hot soda-water and soap, and the brick-work washed with hot lime-white. Such remedies should kill the mildew.

Cracked Pears (W. J. B.).—Your Pears are affected with the *Dendrocitum* fungus, which causes cracking of skins and black spots on the fruits. The roots are chiefly at fault. If you could open a trench round the trees a few feet from the stems, would cut off all roots, and grab under with a broad chisel on a long handle and sever all downward roots, then

refill the trenches, using some fresh soil, would remove several inches of the top soil over the roots, and replace it with fresh soil and some manure and lime rubbish, you may in a year or two get the trees to produce fine clean fruit. If the trees are not too large it may be better to lift and replant them. When this work and pruning (the trimmings being burnt) is done, give the trees a gentle syringing with a solution of caustic soda 1 lb., potash 1 lb., and 2 lb. of soft-soap, dissolved in 10 gallons of water.

Fruitless Apricots (M. T.).—You will do well to lift your Apricot-trees so soon as the leaves have fallen, doing so carefully, so as to preserve all the finer roots. If there be found any long ones, partially shorten them back, as the object of lifting and replanting is to induce more small or fibrous roots to form. Before replanting have the ground to a width of 4 feet from the wall trenched 2 foot deep, and as it is sandy, add some clay or other firm soil, some wood-ashes, and old lime rubbish, as Apricots are very fond of lime in this form. Failing that add some broken fresh lime or fine chalk. A little bone-dust also will do good. Avoid adding animal manure, but in the winter give a top-dressing of long manure to exclude frost from the roots, and add a fresh mulching in May next, after removing the winter dressing in April, to allow the sun to warm the soil.

Diseased Vine-leaf (H. K.).—It is not usual for outdoor Vines to suffer from any leaf disease except mildew, and that not often now. But the season has been so exceptional in relation to low temperature and rainfall that troubles may have occurred to Vines that are not common. Your Vine seems to have been attacked with a warty fungus. Your best course will be to collect all leaves as they fall and to burn them. Also burn all prunings, which should be done early in the winter. Then gently syringe or spray the Vine with a solution of caustic soda 1 lb., commercial potash 1 lb., and soft-soap 1 lb., dissolved in boiling water 1 gallon, 9 other gallons being added, and when used to be quite warm. Or, if you prefer, add to the 1 gallon some clay, and make a paint. Coat over the whole of the Vine-stems with it, and leave for the winter. That may kill the fungus.

Mildew on Vines (H. W. Mason).—That your Vines and Grapes are suffering from a bad attack of the mildew *Oidium Tuckerii* there can be no doubt. Both Grapes and leaf sent are coated with the white mould of the fungus. It is very easy to conceive that in a house of small glass panes, the Vines too near the glass to enable air to circulate over the leaves, and the rods and laterals far too thick, especially in a wet, cold season, mildew would result. The Vine-rods should be fully 10 inches from the glass, and the upward rods 3 feet apart, being each winter hard-spurred back to one strong bud. Cut off all Grapes now; then make up a solution of sulphate of copper 1 lb. and fresh lime 1 lb., dissolved separately, the first in 10 gallons of water, the lime in a pail; add 2 lb. soft-soap, then well spray or gently syringe the whole house and Vines with it, following it, whilst damp, with a dusting of sulphur. Collect all leaves as

they fall and burn them. Give the Vines later in the winter a second syringing. Well wash and paint all woodwork and glass with hot soda-water, and well lime-white all brick-work. Even then it may be found needful to lift the roots and replant them, adding fresh soil. These attacks are difficult to overcome, except by drastic measures.

Scalded Grapes (H. W. N.).—The berries of both Alicante and Lady Downe's Grapes sent show distinct evidences of suffering from scald. They all have brown spots or scalds near the stems. This injury is due to sudden bursts of sunshine on the berries whilst they are still moist. It is sometimes due, also, to imperfect glass, which concentrates rather than disperses the sun's rays. It is possible, also, that roots are at fault, and have gone out of the prepared border into sour soil. In any case, it will be well to alorton back the Vines rather hard so soon as the leaves fall, to lift the roots, and replant them more shallow, adding to the border some fresh turfy loam, wood-ashes, and bone-dust. Use animal-manure only for top-dressing. The excessive rains of the season may have promoted damp in the house materially. Lifting and replanting the roots will help to correct that another year.

Fig-trees not fruiting (H. N. G., Bath).—We have been greatly interested, although, we fear, not instructed, in reading your suggestion as to the sexuality of Figs, as it is the first time we ever heard of it. We can assure you at once that your theory is entirely wrong, that there is no sex in Figs, and that fruitlessness is due to other causes than these you so confidently propound. Possibly some of your trees may have been raised from seed taken from dried, imported Figs, and seedling trees often have been barren for many years. They have been fruited only when grafted on to some old tree. Then Figs are often barren because they have far too much root run, and then produce shoots that are gross, soft, and fail to ripen. Such shoots never carry fruit. Again, the soil may be very deficient in phosphates and potash, and that would cause barrenness. You do not tell us how your trees are growing. Are they bush trees in the open, or are they on walls outdoors, or are they under glass? However they may be grown, it seems certain that they have far too much root room. In the gardens of the Royal Horticultural Society is a collection of every known variety, some eighty in number, all in pots of diverse sizes, and many of them large bushes, yet every one fruits well two or three times each year, as they are started early in heat. But that fruitfulness is due first to the very limited area allowed the roots, and, second, the feeding with manures they get from the surface. You had better in October open deep broad trenches just in front of or round your trees 2½ feet to 3 feet from the stems, cut off every root, refill the trenches, fork up the surface over the roots, and give to each tree ½ lb. of superphosphate, kainit, and sulphate of ammonia, forked in, and give two other dressings next spring and summer. Also, in October thin out the branches well and nail in only the best ripened shoots.

GARDEN WORK.

Conservatory.—I beg to thank the Rev. F. H. Law for his interesting note, enclosing cuttings of *Diosma ericoides*. I happened to say in a previous issue I had lost sight of this useful and interesting old plant, and this led to the reverend gentleman very kindly sending samples of the shoots for identification, as he was in doubt about its name. Very often, when really good old things are turned out of the gardens of fashionable people, they find a home in the rectory garden, and so are not altogether lost to us. The demand for long, stiff-stalked flowers for cutting has driven out of cultivation many interesting and beautiful plants which do not come up to the fashionable standard. I am told by Belgian travellers that there is an increased demand for Camellias and that they are likely to come back to us again. They are among the brightest things we have in winter, but are not of much use for cutting. There was a time when ladies commonly wore them at balls and parties, but they are not seen now, though it will be an advantage to have a few good bushes in the modern conservatory. Of course, they are still found in old-fashioned places. The Acacias, too, are lovely as the days lengthen after Christmas. One or two may be had in flower before Christmas, but soon after they are plentiful. They are best grown in pots. When planted out they make very rapid growth—almost too rapid, if the house is not very large—but when in pots they can be placed outside in summer, and will come back better for the cutting. In fact, all greenhouse plants are better in the open-air for a month or two in summer. Attention must now be given to the reduction of the climbers. The light is wanted by the plants below, and they must have it or the growth will draw and become weakly. The early-flowering *Chrysanthemums* are coming in now and will help to brighten up the house. There are still plenty of late Lilies, as well as retarded bulbs of *Lilium longiflorum*, but there will be plenty of late lancifoliums which have been brought on outside. *Achimenes* in baskets have been lovely, and are now getting past their best, and may be moved to another house and have less water. Other baskets can be filled with winter-flowering *Begonias* and *Bouvardias* to be coming on. The old *Coronilla glauca* makes a pretty basket plant in winter. In regulating the growth the shoots can be tied to the rim of the basket, and permitted to grow down.

Stove.—Now that the plants are returning from other houses and pits, fires must be kept down so that the things from cool structures may settle down and not be unduly hurried. In country houses through the autumn and early winter there is usually a good deal of company for the shooting parties, and a very large demand is made upon the garden for plants for table and room decoration, and there must also be abundance of flowers for cutting. The stove has to supply most of the plants for table decoration and a good deal of the cut stuff required. *Asparagus plumosus* and *A. Sprengeri* are useful, as is also *Smilax*, and these things cannot be improvised. A few large *Crotons* that one can steal a few leaves from will be useful, and the foliage of *Cissus* discolor comes in well for flat decoration on the cloth. Very few ladies require the same arrangement more than once, so abundance of material will be required to give the necessary changes. The plants for table use will have to be in 5-inch pots chiefly, though occasionally small pot stuff can be used—*Crotons*, *Dracenas*, *Pandanus Veitchii*, small Palms, especially *Cocos Weddelliana*. All plants for this work should be light and graceful in habit. Small Maiden-hair Ferns and *Caladium argyrites* form a nice change at times. A good many years ago (I forget how many) the Royal Horticultural Society offered prizes for collections of plants for dinner-table decoration, and it was stipulated that the plants should be small standards of a clear stem of 18 inches to 20 inches in height. But, somehow, this kind of plant never became popular. The idea was that the guests could see across the table under the foliage. Now plants of low growth are chosen that can be seen over, and the effect is much better; besides, it is not

every plant that will form a nice, evenly-balanced head as a standard, and they take time to produce. The idea was well enough forty or fifty years ago, when the small Box-leaved and Myrtle-leaved Oranges were common and were full of ripe fruit in winter. Some of these little Oranges would be a nice change now, just for once, but they would be voted too stiff for general use, though they might come occasionally to form a contrast and as a sort of link with the old days. There were strong men before Agamemnon, and there was good gardening in Louton's time and earlier. Night temperature for stove now, 60 degs. to 65 degs., with rather free ventilation during the day.

Cold-frames.—These are now full of *Primulas*, *Cinerarias*, and *Cyclamens*; but the time is near when a clearance will have to be made, especially as regards the early-flowering *Cyclamens*, which are now coming full of buds, and require a drier atmosphere. All the early-flowering bulbs should now be potted. Some, such as Roman *Hyacinths*, *Freesias*, and double *Daffodils*, are now making roots. The earlier these are potted the sooner they flower, and they will not bear much heat; therefore, to flower at Christmas or New Year's Day, early potting is necessary. *Hyacinths* after potting should be buried in Cocoa-fibre or ashes while they are making roots, which is generally about six weeks or so; they may then be taken to a cool-house for a time, and moved later to a little warmth. Cold-frames during autumn and winter are wanted for many purposes; they are often filled with Lettuces and Endives for winter use, and Cauliflowers for setting out in spring, and later will be required for forcing vegetables of various kinds on hot-beds. No gardener has too many light, movable frames, as so much can be done with them.

Ripe Grapes.—It is pretty well understood that it is better for all Grapes to be ripe before the sun has lost its power; but this has been a difficult season, as the weather has been often bad and the sun hidden under the clouds. Therefore, there are a good many Grapes this season that will have to be finished off with fire-heat. There have been a good many green Muscats at the recent shows that will take time and warmth to finish, and this should be seen to now. Lady Downe's and Gros Colmar also may require a little help. Black Hamburg and the Sweetwater will do with plenty of ventilation, though there may be cases where the wood may require a little help to ripen, even if the Grapes do not, though something may depend upon the weather during the latter half of September.

Window gardening.—The beauty of window-boxes may be prolonged by careful picking over and a little stimulant in the water. Take all succulents, such as *Cactuses* and the choicer kinds of *Aloes* and *Mesembryanthemums* indoors, or place under cover. Pot up *Solanums*, *Arum Lilies*, *Eupatoriums*, and *Salvias*, and place in the shade for a time.

Outdoor garden.—Look over the early-budded *Roses*, and loosen ties and rub off young shoots from the stems of standard Briers. Buds which remain dormant through the winter make the best heads. Every grower who wishes for plenty of *Roses* through the summer should bud a few *Roses* annually. It is a necessity for those who wish to attain any position at the *Rose* exhibitions. There is a demand for *Teas* and *Hybrid Tea Roses*, and this demand will increase, for it is found that the *Tea Rose* of the present day is more hardy than its predecessor was thought to be; at any rate, we do not hear so much about the tenderness of the *Tea Rose* now. Some of this may be due to the altered conditions of culture. Formerly, *Tea Roses* were planted under similar conditions to other *Roses*; now, those who wish to grow *Tea Roses* well group them together, drain the sites, and deepen and improve the soil, and, where necessary, raise the soil above the natural level. Some of the best beds of *Tea Roses* I have seen lately have been in the shape of sloping banks, backed with shrubs. Plant out *Narcissus* intended to produce flowers for cutting. I have always found *Madonna* or old white Lilies do best in rather gritty soil, and not too deeply planted. Cuttings of choice evergreens will strike now in

shady site under handlights or frames. Sow Grass seeds to form new lawns this month, and commence planting evergreen trees and shrubs.

Fruit garden.—Apples and Pears have grown rapidly since the rains set in. Lord Suffield is still one of the best early cooking Apples, but it bears so freely that the trees never got large. Mank's Codlin is an old Apple, but takes some beating as an early culinary fruit, and it is one of the few Apples which may be easily propagated from cuttings. If good-sized branches are cut off and planted firmly in a shady border for the first year, there will be well-rooted bearing trees in a couple of years. I think everybody with a couple of lawns should plant a Mulberry-tree. Apart from its fruiting capacity the tree is an interesting one, and it may be planted in the town garden. It takes some time to work up a bearing tree, as the Mulberry will not bear much in a young state. If one could save off a branch from an old fruiting tree and plant it firmly, a bearing tree would then be soon obtained. Royal Sovereign Strawberry is still being planted largely. It is hardy and reliable. Leader also is receiving attention. Strong plants set out this month will soon get established, and will bear heavy crops of fine fruit next season. The Duke Cherries as pyramids on the Mahaleb-stock make very fertile trees in a short time, but the White Heart Cherries grow too freely on this stock, and when they flower the trees are generally fruitless as pyramids. There appears to be a good deal of American-hlight in town gardens. A clear should now be made to clear this out with paraffin and a brush.

Vegetable garden.—Vegetables are now plentiful and good. There is a little disease among Potatoes in some districts, but bright, sunny weather will check it, and the crop is better than might have been expected from the drought of the early season of growth. Outside Tomatoes are a poor crop generally, but with bright weather they will ripen, and they realise fairly well, though there is not much money in Tomato growing. The culture is understood by all who have gardens, and many people grow enough for their own use. Thin the foliage and get the fruits ripe before the frost comes. Fruits will ripen on the plants when fully grown, but the flavour is not so good as when they ripen on the plants fully exposed to the air and sunshine. Make up Mushroom-beds in buildings as fast as manure suitable for the purpose accumulates. Outside beds should bear freely till the temperature falls considerably. The seed-sowing is over for the season now, but Mustard will be sown under glass now in succession as required. Cabbage-plants can be set out for spring use, and apere frames filled with Lettuces and Endives with the lights off for the time being. Continue to earth up Celery in succession, and draw earth up to Leeks. Hay-bands should be wrapped round Cardoons as preliminary to earthing up for complete blanching later. Use the hoe as freely as possible among growing crops, and do not permit a weed to seed.

E. HORDAT.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 15th.—Spare bulbs of Snowdrops have been planted in good-sized irregular patches round the margins of lawns. Spare *Narcissus* will follow in the same way immediately. Bulbs which have been forced a little under glass are used in the same way, and we hope in time to brighten up the places immensely. More bulbs of various kinds have been potted, and in some instances boxed, to make roots ready for forcing. Tulips are in boxes covered with litter.

September 16th.—*Salvias* planted out last year been cut round with a spade ready for lifting. Other things which are planted out, such as *Eupatoriums*, *Solanums*, etc., have been, or will shortly be, lifted and placed in suitable sized pots in a shady position. We find the north house very suitable for this kind of work just now till the roots get to work again. Then they can be moved into the sunshine. Newly-planted Strawberries are watered occasionally when required.

September 17th.—Foliage has been thinned on outdoor Tomatoes to hasten the ripening. We are still gathering a few good Red Warrington Gooseberries, which have been protected by hexagon netting. We are thinking of planting a north border of this Gooseberry and Red Currants, to be easily netted up and kept for winter. Belle de Fontenay is a good autumn-bearing Raspberry, the fruits being large and nice. Late Grapes ripening are still supplied with liquid-manure.

September 18th.—During the autumn and early winter we intend altering and extending the beds and borders for hardy plants and shrubs. Roses also, especially Teas and the Rambler, will have attention. This is a season of programmes, which we hope to carry out if possible. At any rate, we never as a season without making some change in the permanent features of the place, mainly in the view of introducing new features and plants.

PLANTS AND FLOWERS.

ROSES.

DARK HYBRID PERPETUAL ROSES.

A PESSIMISTIC grower said to me a few years ago that the Hybrid Perpetuals had had their day. My reply was a decided negative, for, much as I love the exquisite Teas and Hybrid Teas, I could not forget the superb colours, the bold, thick-petalled blossoms, and, above all, the powerful fragrance of the majority of the dark Hybrid Perpetuals. The illustration of Ulrich Brunner is one of the most beautiful of a Rose I have ever seen, and portrays that fine variety to the life. It is one of the best light red Roses grown. I think if I could only grow one red Rose it would be Ulrich Brunner. There are Roses more perfect in colour, but I know of none so good in growth or more useful in the garden. Alfred Colomb is another

grown I do not consider one requires Duke of Wellington excepting for show—then there is ample room for both. Dr. Andry, Duke of Edinburgh, Duchess of Bedford, Duke of Albany, Eclair, and Earl of Pembroke are all thoroughly good crimson Roses, and quite distinct from each other.

Of the rich velvety crimson Roses, a type of colour so much sought after, Charles Lefebvre is certainly the best. It is a fine, bold, semi-imblicated flower, the growths strong and sturdy, foliage handsome, and it is a kind that pays for liberal feeding and free disbudding. Another grand variety that everyone may succeed with is Eugene Furst. The petals are deep, not very smooth edged, but colour and also growth are so good that there is no dwindling of the plants as is too frequent among dark Roses. Triomphe de Caen or Prince Arthur is a Rose everyone should grow. It is of darker colour than General Jacqueminot, but no doubt is a seedling from this, as it

Rose Ulrich Brunner. From a photograph by F. Mason Good.

September 19th.—Chrysanthemums are checked daily, and several times a day, to kill twigs and do other routine work. The buds incurves are being taken. I confess to a weakness to these formal flowers. There is plenty of variety among them, and now even the Queen of England is not lacking, but the Queen of England is disappearing mainly through the pruning required to produce a good bloom. Apples and Pears are gathered before they are quite ripe to use.

September 20th.—Fine days are given up to working up Celery and battling with weeds, which have grown fast since the rains came. More Lettuces and Endives have been planted in the south borders. Potted a lot of double Pansies for forcing. They will not stand much heat, but will rise up well in a night temperature of 55 degs. to 60 degs. We have been obliged to begin fires again. Store plants, Cucumbers, late Melons, and late Grapes want to be in touch of the warm pipes occasionally.

medium red of first-class quality, one of the best for autumn blooming, of perfect high-centred form, good in growth, and very fragrant. Marie Baumann much resembles the last-named, but is, perhaps, on maiden plants the better flower. As a cut-back, however, it is not nearly so good. In a small collection both are not wanted, and I prefer Alfred Colomb. Beauty of Waltham is a good light red. Of rich crimsons, Alfred K. Williams takes premier position as a show bloom, but I should prefer General Jacqueminot for general culture. Taken all round, there is even now no better red Rose. On the Manetti this grand old kind is not happy, but on own roots it is a great success. Comte de Raimbaud is a crimson Rose worthy of more extended culture; it is so very reliable and a good grower. So also is Fisher Holmes; one of the best early and late, its handsome if small blossoms are of a very glowing colour, and if not disbudded will give a quantity of lovely buttonhole flowers. Although not identical, if Fisher Holmes be

possesses all its good points. Maurice Bernardin, which passes under various aliases, such as Exposition de Bruc, Ferdinand de Lesseps, and Sir G. Wolseley, is a variety of much merit, distinct from other crimsons, always grows well, and is an all-round good Rose. Horaco Vernet and Louis Van Houtte would claim a place in the best six crimson Roses did they but possess a better constitution. If these are grown, a point worth remembering is to bud a few each year on the Brier. The resulting blossoms are worth this and even greater trouble and expense, for two more lovely Roses we do not possess. Earl of Dufferin, Duke of Fife, and Duke of Connaught are also of more than ordinary merit, the last a lovely buttonhole kind. Victor Hugo I have left until last—not because it is least. In our large collection no Rose claims more attention than Victor Hugo, principally owing to its gorgeous colour. It is not a strong grower, but is a better cut-back than Xavier Olibo. It is not a strong grower, but is a better cut-back than Xavier Olibo. It is not a strong grower, but is a better cut-back than Xavier Olibo.

our leading dark crimsons, and perhaps super-seede Victor Hugo, for it is certainly a better grower.

There is yet another group of dark H.P. Roses, and they are of the blackish-crimson or maroon shade, of which Prince Camille de Rohan is the representative. La Rosiere and Jubilee, if not identical, are certainly too much like the Prince, so that all three are not wanted. Unless highly cultivated, this Rose is apt to come red in colour, and is not then of any great merit. Good phosphatic manures are required to develop this Rose to its best capabilities. Abel Carriere is a well-known kind, and a Rose of more than ordinary merit, seen better, however, as a standard than a bush. At times the flowers are almost coal black. Black Prince is rather too near Pierre Notting, but occasionally it justifies its name.

With the exception of Duke of Edinburgh, all the kinds named above are very fragrant and worthy of culture on that score alone. Where space is available I would recommend that they be grown, for if some approach each other rather closely in colour, they each have their own special season, and by growing all, some good dark H.P. Roses are secured each year.

NOTES AND REPLIES.

Rose Niphete in Banffshire.—I have seen many letters in your paper describing Niphete as a Rose only fit for greenhouse

can be afforded the cuttings during a spell of severe weather, and here, again, sand should be incorporated with the soil. The practice of inserting some coarse sharp sand in each hole before placing the cutting therein is a good one, and does a good deal to assist in root formation. Another plan worthy of imitation is to put a few cuttings in a jar or bottle of water, and pot off when roots have formed.—TOWNSMAN.

Rose Eugene Furst.—The shape of this Rose does not fit it for the snowboard, but its rich velvety colour is so well maintained and its growth so vigorous that it may be regarded as a really good dark variety for the amateur. Several of the very dark Roses are much too full to be beautiful, but Eugene Furst, although the colour is not so intense as in Baron de Bonstetten, I consider a more useful variety for the garden. As with the majority of deep red Roses, it possesses a sweet fragrance, an attribute far too rare in our modern kinds.—ROSA.

Replanting old Rose-bushes (N. E. J.)—We do not think anything is gained in replanting very old bushes of Hybrid Perpetuals, seeing that good yearling plants of best sorts can be procured so cheaply. If you decide to replant it is well to shorten all growths to about 2 feet to prevent swaying by the wind after planting, then in March cut back almost to the ground to induce new growths. The following year the pruning must be regulated according to the vigour of

shoots. Any plants that are "a regular mat" of dead shoots very clearly prove long continued neglect. It is, however, a very common thing with amateurs that they will not allow their Rose-trees to be cut; indeed, we know an instance where a professional gardener to assist a gentleman interested in Rose-growing pruned all his dwarf H.P. Rose-trees, while the gentleman himself looked on and asked as many questions as he thought fit as to "why" and "wherefore." The trees had long been neglected, but they flowered remarkably well, and it was hoped and believed the object lesson had done much good. The following year the gentleman began his own pruning again, and, in spite of the evidences the trees gave as to the need for hard pruning and equally the beneficial results of it, he had merely cut off an inch or two from the tip of a growth nearly 4 feet long. It is in these circumstances that so many good plants are spoiled. Tea Roses and all small-wooded kinds may all be well thinned now of the small pieces and any old wood, but we cannot recommend a general pruning or trimming at this season.

Rose Albert Stopford (H.T.)—This fine Rose has been remarkably good this year and I have formed a high opinion of its merit. I do not know of any Rose with petals of such substance, no mean quality in a wet season and in a dry one the flowers stand well. The variety is reputedly a cross between General Schablikino and Papa Gontier, and, of course, one expects something good from two excellent parents. The growth of Albert Stopford is strong and stout, superior to Papa Gontier. The colour is coppery-rose, deepening in centre of flower; the outer petals are deep carmine. The buds are of a splendid long shape, the open flowers bold, short, and fragrant.—ROSA.

Roses on house-walls (Beginner)—With regard to climbing Roses you must exercise considerable patience, as until you obtain plenty of growth you cannot expect much blossom. Most of the new growths of this year, if well ripened, should blossom next summer, and it would be well to nail these in order to assist thorough ripening. Climbing Roses often appear at a standstill when reality they are making roots, and the subsequent growths will be all the finer. As the soil in the border is somewhat porous, a washing of peat-Moss-litter after its rejection into the stable would be excellent, or other well rotted manure would answer the same purpose. The Rambler Roses on arches will give you much blossom until they have been established about three years. Encourage the growth possible, and do not prune away unless the shoots become too crowded. You will then be rewarded with beautiful masses of blossom from the two kinds named.

Mildew-proof Rosee (N. E. J.)—Unfortunately, varieties that may be considered really mildew-proof are in a very small minority. We have noted the following being as near our ideal as possible: Amie Teas, G. Nabonnard, Mme. C. P. Strassburg, Corallina, Sulphurea, Sylph, Marie d'Orléans, Anna Olivier, Marie Van Houtte. From the Hybrid Teas we select Papa Gontier and the striped sport Rainbow, Clara Watson, Liberty, Marquise Litta, Grace Darling, all the France race, also Caroline Testout and the sport Admiral Dewey, Mme. Wagram, Madame Cadeau Ramey, Mons. Brunel. From the Hybrid Perpetuals, Mrs. George Dickson, Mlle. Clemence Joigneaux, Mrs. Ramey, Wm. Warden. And from the Climbing Teas and Noisettes, Mme. Alfred Carrière, Bouquet d'Or, Longworth Rambler, Aimée Vibert, Billiard and Barre, and Janne Desprez. Most of the Monthly Roses, also the dwarf Polyanthus, are exempt from this troublesome fungus. Roses that are pale yellow or deep yellow in colour without white or pink shadings are, Maréchal Niel, Perle des Jardins, Henri de Beauveau, Mme. Barthelemy Levet, Mme. Eugène Verdier, Duchesse d'Anerstadt, Anaczone, Etoile de Lyon, Georges Schwartz, Souvenir de Mme. Loret, Goldquelle, Mme. Chedanne Guinoisseau, Comtesse de Frigères, and Mme. Honoré Defresne; and from the Austrian Briers Harrisoni, Lutea, Persa-

Irises under Laurels. From a photograph by Miss Wakefield, Nutwood, Grange-over-Sands. (See page 357.)

cultivation. I therefore send you a couple of blossoms, grown in the open bed, without any protection, in Banffshire. It has been planted three years, and is making good, sturdy growth. This last winter was the most bitter for several years, the spring cold and severe winds—10 degs. of frost on June 18th killing all the Beech-leaves even and leaving the trees brown, but not harming the Rose.—M. CLAY, Rothiemay, N. B.

Rosee from cuttings.—One may have a great measure of success with cuttings if only the right sort are selected at the proper time. Talking to a friend a few weeks ago on this subject, he said: "See that plant? That is a William Allen Richardson, struck from a cutting last November, put in a pot, and kept in a frame." The plant in question was carrying several nice blooms, and was making promising shoots. Towards the end of October is the best time to take cuttings, and these should be procured from shoots that have borne flowers, if possible, 6 inches or 8 inches long, the ripest being selected. Young shoots from late growths are useless. In taking the cuttings, too, it is well to remember that the nearer they are cut off to old wood the better, all leaves but one or two at the extreme points being removed. Whether it is intended to pot them from the beginning or make up a bed in the frame, the soil should be of a sandy nature, and should be made fairly firm, proper drainage being insured from the start. In the open border it is best to choose a position where the

variety. Those sending up shoots 4 feet to 5 feet long are usually pruned back to 1½ feet to 2 feet of the ground, whereas such kinds as flower freely are pruned closer, even to within 4 inches or 5 inches. We think 1 foot 6 inches about the right distance to place the plants from each other. The time of year you name is right, but it will be well to heel the plants in for a day or two while you have the bed well trenched. You can remove the foliage and shorten growths before heeling in, which will prevent them shrivelling, and at same time prune roots a little, smooth over jagged ends, and rub off any suckers met with.

Rosee (Swede).—In the case of the Malmaison Rose, all the dead wood should be removed quite down to the head, using pruning scissors or small saw to enable you to cut quite close. This may be done at once. No actual pruning should be done at this time, but small, blind, and flowerless pieces of growth may be cut clean away in every type of Rose, leaving the stronger shoots, such as you describe, to do the work of flowering. With this and many other Roses, the best plan to secure good blooms is to leave no small, thin wood, but to endeavour to promote good, vigorous shoots of the size of a lead pencil. By letting these flower and merely removing the seed-pod afterwards, a good shoot is left for next year. All such shoots should, however, be hard pruned in spring, for it is by these means that the vigour is maintained and the plant furnished with a few really worthy

OUTDOOR PLANTS.

IRISES.

Few appreciate to the fullest extent the German Irises, many, I venture to say, still thinking of them as June flowers, suitable for gardens alone. We forget, possibly, how long before these brightened our borders, the netted Iris reticulata and I. r. purpurea flowered amid the snow and sleet of January, timidly at first, perhaps, but showing in the fitful gleams of winter sunlight the loveliness of their gold and purple blossom. Charming, too, also for early blooming are the Persian Irises, mingling their petals of white, blue, and purple amid their bright green foliage in the first days of February. But when we think of summer and its flowers, it is then that Irises appeal to us, some with blossoms quaintly marked and blotched, some preferring the shelter and the sunshine of a warm border, and rivaling the Orchids in beauty. It is not, however, merely as border flowers that they are interesting. Happy is he who can grow the water or Flag Irises. Any one who has cruised on the Norfolk Broads will tell you

I. Bakeriana which follow. I. germanica is the commonest of the genus, the Flag Irises of the town garden, growing where one would least expect to find them, amid the dust and impure atmosphere, often flourishing most where other plants fail, and giving us blooms diversified in colour. Where the soil, too, is dry the Iberian Iris (I. iberica) will serve us well: the flowers are large, flecked, and spotted, with standards white, falls veined with blue and purple over a yellow background, blossoms singularly beautiful and elegant when cut with some of their flag-like foliage. One of the choicest of the Flag Irises is Monnierii, well fitted for a border where the soil is moist and rich, a late blooming, sweet-scented sort with yellow flowers margined with white. I. Pseudo-acorus has already been alluded to, it is the commonest of all, the yellow water Flag, and will grow in any moist and damp situation. I. pallida loves a moist, deep root-run, but does well even when planted on a dry soil; the blooms, however, are not so fine nor do they last so long as when planted under cooler conditions. A spring blooming dwarf Iris is to be found in pumila, seldom attaining more than a height of 7 inches or 8 inches, flowers blue and purple. English

warm and sheltered borders many weeks, often until the later days of December. LEAUFERST.

The illustration on page 386 shows a very successful Iris bed, grown in the driest possible position, virtually under Laurels. It is difficult to know what to grow in such a place, and this might be a useful suggestion to others.

A. M. WAKEFIELD.

Natbrook, Grange-over-Sands.

BEDS FOR HARDY FLOWERS.

(REPLY TO "A. M. G.")

In our opinion, judging by the size of the whole series of beds, we regard them as small for well displaying good hardy perennials. In other words, the number of beds is too great for the limited area. If, however, you are leaving them as now arranged, we would suggest as follows: Nos. 4, 8, 10 to be planted with Hydrangea paniculata grandiflora, with Aubrietia as a carpet and Crown Imperials to flower in March and April. Nos. 2 and 6 may be filled with Crimson Glove Carnations and Narcissus poeticus ornatus, with a margin, say, 9 inches wide, of Muscari conicum. Nos. 9 and 11 may be planted with Delphinium con-

Irises in shade. From a photograph by Miss Mabel Gaisford, The Grove, Dunboyne.

that in June their bright yellow blooms, which fringe the water-ways and fill up the entrance to the dykes and narrow channels, add beauty to the landscape, however much they may impede the progress of the yachtsman. These are the flowers that blossom with Water Lily and Forget-me-not, with Meadow Sweet, Marsh Orchis, and Crowfoot--

"Dwelling by still rivers,
Or solitary mere,
Or where the sluggish meadow brook delivers
Its waters to the weir."

There is a charm about the Iris of our streams and low-lying meadow lands, but with garden plants we most of all have to do, and grown on borders, or adjacent to lawns, partly in the shade, so that their blossoms are gradually developed, they continue longer with us, having maybe, as in the illustrations, a background of foliage, which only serves to heighten the wealth of their gorgeous tints.

Let us then consider what varieties are best for providing us with hosts of flowers for our vases and epergnes, as well as giving us blossoms over the longest period. As already mentioned, there are the Netted Irises which are fragrant and bloom early. Similar in colour and sweet scented also are the flowers of

Irises again belong to a distinct class, blooming a little later than the German, tall and stately, possessing many self colours, having rush-like foliage. I. orchoides is extremely beautiful, differing entirely from any other, and preferring a warm, sheltered situation. I. asiatica closely resembles the German, but the blossoms are finer. But it is doubtful whether any of those mentioned have ever been so popular as the Spanish Irises are to-day. To say that they are extremely light and graceful, and, therefore, particularly adapted to table decoration, will grow in any open situation in a free, well drained soil, flower freely, are possessed of delicate colour, and that bulbs are cheap, is only giving expression to facts that are now well known. Not many, however, when planting the bulbs in beds in September remember to pot up a few for early spring blooming in the house. Not the Spanish alone lend themselves to forcing, but many of the other sorts, if lifted from the open and brought under glass in spring, will bloom freely. Irises to be effective should be grouped together, as here depicted, and in planting one should remember those that bloom late as well as at midsummer, kinds like alata, whose lilac blossoms flecked with yellow remain with us on

spicum, D. Lavender, D. Lifeguardsman, and D. Celestial for the central portion, with Liliun candidum in clusters around, and, again, a belt of such Phloxes as Etia, Coquelicot, Embusement, Lothair, all red shades, and Sylphide, Mrs. E. H. Jenkins, Avalancher, Panama, all pure white, arranged at will. Outside these a few Pyrethrums may appear, Mrs. Bateman Brown, crimson carmine, Hamlet, pink, Sherlock, carmine, coccinea, fiery red, to be interspersed with Aster Amellus, A. acris, A. laevigatus, etc., and bordered with a few clumps of Daffodils, as Emperor, Empress, Sir Watkin, Golden Spur, and princeps, with such plants as Aster alpinus, Phlox divaricata, Arnebia echioides, Armeria cephalotes rubra, and Phlox setacea in variety at the margin proper. The remaining four beds, Nos. 1, 3, 5, 7, could be occupied with Japanese Anemones in three shades, Liliun tigrinum, Galtonia candicans, Gaillardias, such double Pyrethrums as J. N. Twerdy, Capt. Nares, Aphrodite, Ne Plus Ultra, with Iris pallida, Queen of May, L'Innocence, Darius, Mrs. Darwin, Chelles, Dr. Bernice, etc., hybrid Columbines, Delphiniums, Belladonna, Lupines, Coreopsis, and the small Day Lilies, as Hemerocallis flava, H. Thunbergi, etc., Dornicum,

Scabiosa caucasica and alba, a few select Michaelmas Daisies, as *N. B. densus*, *cordifolius* and *elegans*, *turbinellus*, *Lindloyanus*, *Esme*, *N. A. Mrs. Rayner*, *N. A. roseus*, etc. The above are 3 feet high or more, and dwarfier things to complete the beds may consist of good Self Carnations, double Pinks, *Heuchera sanguinea*, *Dianthus barbatus magnificus*, *Campanula Hendersoni*, *C. carpatica* and *alba*, *C. turbinata*, *C. glomerata speciosa*, *Iris nudicaule*, *Primula denticulata*, *P. Cashmorianae*, *P. rosea*, the new double whits *Arabis*, *Anemone apennina*, *A. Pulsatilla*, *A. sylvestris*, with *Aubricitias*, etc. Tufts of *Moerhousias*, groups of *Lilics*, of *Daffodils*, and of *Gladiolus*, particularly the *Lemoinei* section of the latter, may also be added for filling in small places and the like, and thus provide a sort of *mutum in parvo* style of grouping wherein variety and a long season of flowering would be the leading features.

TUFTED PANSIES—PREPARATIONS FOR AUTUMN PROPAGATION.

A WELL-GROWN lot of Tufted Pansies will blossom from March until October, and even later when the position and soil are suitable, and to take cuttings from plants blossoming freely means spoiling the display for sometime at least. Readers who desire to grow these plants largely, and who also wish to propagate annually by cuttings, would find planting a few old stools in any out-of-the-way place in the garden, where, of course, they obtain a certain amount of sunshine each day, answer their purpose. These stock plants can be kept cut back from time to time, and as a result they will form veritable tufts of beautiful, sturdy, short-jointed growths. If some light and gritty soil can be worked into the crowns of these old stock plants during the late summer, many of the pieces will quickly emit roots, which may be detached and planted out in a bed specially prepared for them, and, if need be, again planted out in their permanent quarters before the hard weather sets in. Another method of dealing with old stock plants of this description is lifting them when their shoots are of the desired length and dividing them. By these means quite a large stock can be raised very quickly. This method of increasing the stock of new and choice sorts is followed by one of our leading trade growers. When the pieces just referred to have become established they soon form new growths, and in a short time they in turn may be divided. By this method of raising plants there is very little cutting about of the divided portions of the stock plants likely to take place. Here and there an unwieldy piece of coarse growth may have to be cut back, but in almost every instance the shoots will have roots adhering. In warm weather it is well to shade the cutting beds or cold-frames into which these fresh pieces are put, and in the early evening to sprinkle them with water from a fine-rosed can, as green-fly and red-spider are encouraged by dry conditions.

In the case of those who do not wish to spoil their display by robbing the plants of their young growths at this season, it would be better to cut back a plant here and there among the more crowded of those in the beds and borders. With ordinary care the beauty of the display may be scarcely interfered with. Cut back the coarse growths, as well as those which are weak and elongated, to within an inch or two of the crown of the plant, and have ready a quantity of light, gritty soil to work into and around the cut-back specimens. Equal parts of loam, leaf-mould, and coarse sand or road-grit, passed through a sieve with a coarse mesh, is an ideal compost with which to mulch the plants. It is also a good plan to slightly loosen the soil round the cut-back plants. In dry weather copious supplies of clear water should be given. It is astonishing how quickly the plants regain their vigour, and, in consequence, cuttings of a desirable kind and in goodly numbers may be detached, and in some cases with roots freely omitted from their base.

Where only a limited number of plants is required, the reader may get these from the plants in flower. One or two cuttings from each plant will, no doubt, meet the requirements of some growers, and by carefully

detaching these with a sharp knife the plants will not be interfered with. Only those shoots of recent growth should be taken, and if they be made into cuttings of about 3 inches in length, no better material could be chosen. The cutting-bed should receive some consideration, and although some put the cuttings into cold-frames, I prefer to give them quite hardy treatment, making up a bed outside for their reception. At this time the cutting-bed should be arranged in a nicely protected quarter of the garden, with a warm aspect. Make up the soil some few inches above the ordinary garden level, seeing that this is of a light and gritty character. The surface should be made as even and level as possible, and slightly firmed. An hour or two before the cuttings are to be inserted give the cutting-bed a good soaking with clear water from a fine-rosed can, and all is then ready for inserting the cuttings.

D. B. C.

WHITE FLOWERS.

If you will allow me, I think I can add to the list of white flowers for "S. E. P." Earliest of all come double white Primroses, Snowdrops, double white Violets, and single *Acaerulea* The Bride, closely followed by double white Stocks. All of these are good cut flowers for little bowls or troughs. In addition to *Narcissus poeticus*, *N. p. ornatus*, and *N. p. fl.-pl.*, there are several good white flowering bulbs: double and single Tulips (early and late), *Allium neapolitanum*, *Anthericum Liliastrum*, *A. L. majus* and *A. Liliago*, *Brodiaea capitata*, *B. congesta*, *Camassia esculenta alba*, *Snowflakes* (both spring and summer), *Lilium candidum* (the lovely Virgin Lily), *Gladiolus The Bride*, *Ornithogalum*, the best being *arabicum* and *pyramidalis*, *Trillium grandiflorum*, *Triteleia biflora* and *T. uniflora alba*, *Scilla natanis alba*, *Ranunculus*, English and Spanish *Iris*, Dutch *Hyacinths*, several varieties of *Anemones* and *Grape Hyacinths*. To your list of plants I add German *Iris*, single and double *Paeonies*, *Aquilegia* (the best being *Munstead White*), *Canterbury Bells*, *Phloxes*, *Lupins*, *Christmas Roses* (I should have put these as January flowers), *Agapanthus umbellatus albus*, *Spireas*, *Cimicifuga*, *Dahlias*, *Snapsdragons*, *Saxifraga trifurcata* (the Stag's-horn S.), *Pinks*, *Carnations*, white *Ice-land Poppy*, *Scabiosa caucasica alba*, white *Tree Lupin*, white *Perennial Cornflowers*. The whole of these are good, hardy, inexpensive, and, I can vouch from personal experience, good for cutting. The *Canterbury Belle* are properly biennials, but they last for several years in our hot, dry soil. A few annuals should be added: *White Sweet Peas*, white *German Scabious*, white *Gypsophila elegans*, and white *Jap. Asters*. *White Tufted Pansies* make a most exquisite table arrangement in shallow troughs with their own sprays. *Lily of the Valley* should also be grown. Finally, to carry on till the *Christmas Roses* are in flower, there must be *Chrysanthemums*. My list, in addition to the Editor's, will, at any rate in the west country, give flowers all the year round with the help of *Roses*, *Clematis*, *Mock Orange*, *Lilac*, white *Weigela*, double white *Cherry*, *Deutzia*, *Hydrangea*, *Magnolias*, *Viburnum*, *Laurustinus*, *Exochorda Alberti*, and *Jasminum*.

A. BAYLON.

Dartish, S. Devon.

NOTES AND REPLIES.

A rose-coloured border.—Being overrun with rabbits I am obliged to have most of my flowers in a walled kitchen garden, and this year, quite by chance, my border which runs on each side of the middle path has been all shades of rose colour with *Shirley Poppies*, *Salmon Queen Clarkia*, *Phlox dentata* shades, *Malope grandiflora*, *Pink Lavatera*, and *Snapsdragons*. At the end of the walk the colour scheme is completed by a *Crimson Rambler Rose*, which is being trained to cover an arch over the entrance gate. Had I planned it the effect could not be more successful. I find that the *Salmon Queen Clarkia* is one of the most useful annuals, not only for massing in the border but also for cutting. I did the dinner-table not long ago with long sprays of the *Clarkia* and *Shirley Poppies* of exactly the same shade. I also have a long bed in the same garden with *Sweet*

Peas (in separate colours) in a zigzag ribbon pattern, and Cactus Dahlias in the spaces. I wonder if the *Sweet Peas* are as fine everywhere as they are here this year. A great many of the flowers have four blooms, and I have even found five.—A CONSTANT READER.

Pentstemons, propagating.—The end of September and early part of October is the best time of the year in which to increase *Pentstemons*, all that is required being a cold-frame and a bed made up of loam and leaf-mould, with an addition of coarse sharp sand placed on the surface. After making the bed solid, the cuttings should be dibbled in, giving 2 inches or 3 inches between each, and shading from sunshine, when necessary, for a time, admitting a little air in the frame each day by tilting the lights. In a hard winter *Pentstemons* will survive in a cold-frame, and they are so showy in beds and borders as to warrant one giving them the careful attention now. On a warm, sheltered border, if cuttings are placed in now, a handlight will suffice for covering them.—W. F. D.

Lifting bulbs (*Scotticus Plenus*).—You may lift and replant any of the bulbs named at option, or you may leave all alone as they are. If you decide to lift, it is better than now, in fact, it were better done in July than now, as some, at least, will very quickly be rooting afresh. Those that are best lifted each year are certain *Polyanthus Narcissus*, *Tulips*, and *Anemones*. This, however, entirely depends upon what they are and the class of soil in which they are growing—an important item, concerning which you give no information. Some *Anemones* are best left alone, other kinds are better in certain soils if lifted each year. You give us no information as to what kinds you refer to, and the genus is very large one indeed. *Chionodoxa*, *Scillas*, *Winter Aconites*, *Crocus*, *Snowdrops*, if the common kinds, may go on in the same soil for years, while *Narcissus*, *Tulips*, and *Iris* require in a measure periodical lifting in July. All the bulbs you name succeed quite well in the usual sandy loams, though some kinds are found to do quite well in the more clayey soils. Some *Narcissus*—*c.g.*, *poeticus* kind, *incomparabilis* in variety generally, *maximus*, *principes* and *Emperor*—are quite a success when grown in strong or heavy loam, and in particular where such soils are well-drained, a most important item generally.

Sweet Peas 9 feet high.—With growers in specially moist and favoured situations *Sweet Peas* frequently attain a height of 7 feet to 9 feet, more or less, and as they always present a fine appearance, and also make an effective display in the garden when attaining such a height, with its accompanying broad proportions, a result such as this is always worth striving for. Plants of these extraordinary dimensions are not confined to the gardens of those in favoured situations, for this year, at any rate. Ours have never been so grand, nor have they remained in good form for so long a time in all our experience with these flowers. Our collection is grown on the side of a hill with a north-western aspect, and, as a rule, watering occupies the greater share of our time all through the flowering season. The display with us usually ends by mid-August, with an occasional spasmodic interval of bloom in cooler and moister weather. During the present season, except for a few brief experiences of warm weather in late June and July, very little watering has been done. We have now and then in the showery weather treated the plants to a liberal supply of a well-known patent manure, and to this treatment the plants have given a liberal response in the form of blooms of extra excellence. In a normal season, through being on the hillside, unless copious supplies of water are always given, and these persistently, comparatively little growth is made. The water so quickly runs away that the work of watering is made so much the harder thereby. At the time of writing (September 3rd) our plants vary between 7 feet and 9 feet in height, and they are very handsome indeed. Never has there been so prolific a display and the quality of the blooms so fine. These facts go to prove how abnormal is the season we are passing through, and also how extraordinary are its results. The stronger growing kinds in our collection

are: Lovely, Hon. Mrs. Kenyon, Mars, Duke of Westminster, Black Knight, Prince of Wales, Miss Willmot, Prima Donna, and Salopian.—D. B. C.

Walled-in gardens.—There are many people, I imagine, who, in consequence of the bleakness of the locality in which they reside, are hindered to some extent in growing certain subjects in their gardens, and instead of planting what they like, are obliged to be content with what will thrive. This is so very often in many parts of Scotland and the north of England, where tender things like Tea Roses, and Crinums, Clematises, Tritomas, Passifloras, Lilies, etc., die off during a hard winter, despite the temporary measures that may be adopted for their protection. I knew a man who lived in Cumberland, in a cold, exposed part, who tried Roses for several seasons, but had eventually to give up the idea, owing to the adverse conditions he had to encounter in his garden, which was open on all sides, and I doubt not that his experience is only that of others similarly situated. But in a walled-in garden what a deal one may do, and to what use walls may be put for the culture of fruit-trees, climbing plants, etc. In the matter of

ent flowers. *Coreopsis grandiflora* is one of the most free flowering plants that it is possible to grow, and must be replaced with young stock every year. Canterbury Bells in all shades of colour, Sweet Williams, Antirrhinums, and Carnations of the Grenadin type, also the always welcome Cornflowers, and many plants that are really annuals, if sown in spring are equally effective. Sown late in summer and treated as biennials, many a waste corner may be rendered very pretty by scattering any spare seed over it at this time of year and leaving the plants to flower. Many kinds of Poppies, too, make splendid masses of colour treated in this way.—J. G., Gosport.

Exhibiting hardy flowers.—This is a matter which has never yet received the consideration it deserves. The indifferent manner in which many delightful flowers are staged is not confined to the local shows throughout the United Kingdom. It is quite distressing sometimes to see bunches of our best hardy flowers jumbled up together, with little or no effect, and often with about twice as many sprays of blossoms in the bunch as are really needed to display the subject properly. The idea in the minds of those making the exhibit appears to

tightly packed together, with stems altogether out of proportion to the subject exhibited.—W. V. T.

TREES AND SHRUBS.

FLOWERING CLIMBERS.

Roses are amongst the loveliest of our climbing plants, but there are many others excellently adapted for covering porches, verandahs, pergolas, summer-houses, and trellises that are most attractive in their flowering seasons. Of these the Clematis family occupies a foremost position. The large flowered Clematises of the Jackmani, patens, florida, and lanuginosa sections, with their great blossoms, double and single, ranging in colour from deepest purple, through varied tints of mauve and lavender to white, are deservedly favourites, so striking is the picture they present when at the zenith of their display. These, however, are of less vigorous growth than many of the species, which, though producing smaller and less deeply-coloured flowers, are equally effective. *C. balerica* or *calycina* is valuable on account of its early flowering, bearing its white, purple-spotted flowers in February. Towards the end of May and in the beginning of June the beautiful *C. montana* perfects its masses of ivory-white star flowers, while early in September the Virgii's Bower (*C. flammula*) is shrouded in a veil of small, sweetly perfumed white blossoms, followed later by the very similar *C. paniculata*, whose flowers are Hawthorn-scented.

The yellow-flowered *C. graveolens* is also an attractive plant and a rapid grower. Honey-suckles, with their trails of odorous blossoms, are well fitted for the porch, as is the white Jaemino, on account of the sweet scent that is wafted by the breeze into the house through open doors and windows. The Trumpet Honeysuckle (*Lonicera sempervirens*), with its scarlet and yellow flowers, is the handsomest of its family; but others are well worth growing, such as *L. japonica* and its golden-leaved variety, *L. confusa*, *L. flexuosa*, and the native *L. periclymenum*. The white Jasmine (*J. officinale*), beloved of cottagers, is ever-welcome for its white perfumed flower-clusters, and soon covers porch or archway. The Wistaria is a noble climber, large specimens draping walls for a length of 100 feet with their drooping, lavender flower-clusters. It is, however, enjoyed to best advantage where the walker may pass beneath its drooping, fragrant flower fringe as when used for covering a flat, horizontal trellis. Its one fault is that in its earlier stages it sometimes makes but very little growth, but, when it once starts, it increases rapidly. The Passion-flower is a very vigorous grower, and is practically ever-green, only losing its old leaves as the young ones are pushed out in the spring. Both the old so-called blue Passion-flower and its white variety Constance Elliot are handsome, and provide a second period of attractiveness in the autumn and early winter when hung with their golden-orange fruits. Of the Tropaeolums, the Flame Nasturtium (*T. speciosum*) is a brilliant sight when in flower, but in the south it requires a position where its roots are in constant shade. *T. tuberosum* enjoys, on the contrary, the sunniest site available, where it will produce a profusion of its crimson and orange flowers. *Bignonia radicans* is a brilliant-flowered climber, being a blaze of orange-scarlet in August. The proper title for this plant is Tecoma, but it is better known by the title of Bignonia. The great Bindweed (*Calystegia*) is scarcely a plant to introduce into the border on account of its wandering and aggressive habit, but it is a beautiful sight when covered with its large white flowers. The double Biodweed (*C.*

A cottage entrance. From a photograph by F. Mason Good, Winchfield, Hants.

vegetable produce also it makes very often a difference of several weeks to the bringing of them to table, when grown under a warm wall and protected from north and east. Salads, too, may be had many weeks in good condition, a state of things not always obtainable in exposed gardens in winter and early spring. Anyone who has grown Tomatoes out-of-doors will admit that to plant largely is a risky business, owing to the absence of sun, and in dull, cold periods, as we have experienced lately, but when planted and trained under a south wall there is a much better chance of a crop.—W. F. D.

Sowing biennials.—Biennials include some of the most useful of garden flowers, both for decoration and cutting, and if the seed has not been sown, no time must be lost in getting it done, or there will not be time to get the plants well established before the cold weather sets in. Wallflowers are probably the most extensively grown of all biennials. Then the Stocks of the Brompton and Queen types should also be sown at once. *Myosotis*, one of the old favourites that never seems to lack admirers, and *Pansies* should also receive attention. *Gaillardias* have of late come much to the front, and are invaluable for supplying

be that of creating a dense mass rather than to show off the charms of each individual subject. While this is so the cultivation of hardy plants will never be taken up so readily by would-be growers as would be the case if the flowers of each kind were more pleasingly and naturally set up. Fragrant instances of the kind here referred to are met with at the great show of the R.H.S. at the Temple, and not infrequently do these remarks apply with equal force to the fortnightly displays at the Drill Hall. There appears to be an idea that the stems of many flowers, no matter what their height and characteristics may be, should be cut at about the same length, and in consequence visitors are completely at a loss to know what are the points of merit of the respective subjects. We sometimes find, also bunched together in a glorious mass of colour, subjects which the well-informed know full well are somewhat unattractive or meagre in their display in the hardy border, and which by their representation at the shows are distinctly misleading. There are so many excellent hardy flowers now in commerce that the indifferent things can easily be spared. The fault in exhibiting hardy flowers at local shows generally lies in staging rather small bunches,

pubescens fl. pl.) is, however, not so rampant a grower, and has pretty flesh-coloured flowers. *Polygonum bulbocucurbitum* is a very pretty sight when covered with its large drooping clusters of small lavender flowers. It is of rapid growth, and will soon cover a small tree. Two rarely seen and pretty, but not strikingly beautiful, climbers are *Menispermum canadense* and *Periploca græca*, though the latter is not to be recommended for the neighbourhood of the house, on account of the rather unpleasant odour emitted by its small red-brown flowers. The *Menispermum* has handsome Vine shaped leaves and feathery clusters of yellow-white flowers. S. W. F.

INDOOR PLANTS.

RAISING FUCHSIAS FROM SEED.

Will you kindly let me know whether I can raise Fuchsias from seed, and how to do it, as I have some very fine Fuchsias that have berries on like Cherries?—S. HALL.

[Even if no particularly striking results in the way of new varieties occur in raising Fuchsias from seed, still it is worth doing, because the peculiar enjoyment obtained from growing and blooming seedling plants is of such a nature as to constitute what may be safely termed one of the chief pleasures of gardening. Some care is necessary in order to secure as far as possible good varieties of Fuchsia from which to save seed. Not only should good varieties be selected for seeding, but the flowers must be fertilised so as to obtain the certain qualifications or characteristics of a desired order. Having, therefore, selected the plants from which it is intended to take seed, they should be carefully watched as the flowers expand, and all imperfect blossoms removed, those alone being retained which are quite true to character. From the flower intended to bear seed all the anthers should be cut away; then, by means of a fine camel-hair brush, the pollen should be collected from the flowers to be used for fertilising purposes and laid on the stigma of the parent, tying a piece of thread or some such mark about the flowers to identify those which have been fertilised. A bag made of thin muslin or some such material should be used to cover the fertilised flowers, or bees and other insects will spoil the work of the operator. The seed will ripen just as well outdoors as indoors, but unless means be taken to protect the seed-pods the birds are apt to take them. Like other fruits, the seed-pods of the Fuchsia will fall off the branches when ripe—sometimes before they are ripe—and we remember it was the practice of a good raiser of Fuchsias when a pod fell immediately to press it in the palm of his hand and carefully pick all the seeds out of the pulp with the point of a penknife, and then spread them out on a clean sheet of writing-paper, leaving each seed at a little distance apart from its fellows. Then for an hour or two the seeds were placed on a shelf in the sun, and covered with a piece of glass to keep them from being blown away. After they were dry the seeds were placed in a wooden or paper box, with a little dry silver sand about them to preserve them till wanted for sowing. It is not difficult to obtain Fuchsia-seed, but it is much better to sow twenty seeds obtained from carefully fertilised flowers than three hundred selected indiscriminately.]

TIME TO SOW.—This will vary according to the means of protection at command; if it be a mild, open winter the beginning of January is a good time, or if then the weather be wintry and ungenial it may be delayed until February; but, generally speaking, the earlier in the year it is sown the better. The seed germinates best when grown in a propagating house, heated on the tank system, using for the seed shallow pans filled with a light, well-drained soil, which should be flattened down to a smooth surface about $\frac{3}{4}$ inch from the top of the pan, and on this level surface the seeds require to be placed thinly, and these should then be covered with $\frac{1}{2}$ inch thickness of fine light soil—sifted leaf-mould and silver sand will answer admirably. The pans should then be plunged in the hot-bed up to their rims, after which water should be applied with a fine syringe to slightly moisten the surface of the soil. Those who have not a propagating-house should delay the sowing for a few weeks until they have a

frame heated by manure, plunging the seed-pans in the same way; but in the case of a manure-bed great care is required in covering at night, in giving air, etc., for if there has been any carelessness in making the bed, or the pans containing seeds have been put into the frame before the bed was properly ready, the seeds will germinate quickly, but will dump off as fast as they appear above the surface of the soil in which they are sown. For three weeks or a month, under the most favourable conditions, the best plan is to keep the surface of the seed-pans just moist, not wet, and frequent examination should be made to see that no insect pests are at them. When the plants have put forth a second pair of leaves above the seed-leaves the strongest should be pricked out into small 60-sized pots, using a light compost for the roots. This gives room for the plants remaining in the seed-pans to grow, and some Fuchsia cultivators are of opinion that this is the time when the seedlings least feel the check of removal. When the seedlings are potted the pots should be plunged in a moist bed, as it tends to keep the roots damp and dispenses with the necessity of giving much water overhead, from the excessive use of which the young plants frequently dump off at the surface of the soil. Heat, moisture, and shade are required at this stage of the young seedlings' growth, and on no account should they be allowed to receive a check, for their early and successful blooming entirely depends upon their treatment at this stage. As the plants make growth the leading shoot should be neatly tied to a stake, and when the small pots become filled with roots they should be shifted into 48-sized pots, and in them the plants may be flowered.

There is a wonderful charm in watching the opening blossoms of seedling plants, even if they do not exhibit qualities above mediocrity, but they frequently show characteristics of much value, particularly if due care has been taken to select proper parents. Seedling Fuchsias, if of a good strain, generally grow freely and flower profusely.]

PLANTS TO GROW UNDER STAGING.

(REPLY TO "RUBBING.")

FOR your house No. 1, the following plants would be available for the purpose you name: *Begonias*, the more vigorous varieties of the *Rex* section, do well under such conditions if there is no heavy drip on the foliage. *Cyrtolera* (*Episcia*) *chontalensis*, *fulgida*, and *melanica*: These are all creeping plants with prettily-marked velvety leaves and bright red flowers. *Pilea repens* and *minima*: Both of these are good climbing plants for a lamp wall, to which they attach themselves without trouble, whilst they will also clothe the ground or pillars used for supporting the stage. *Fittonia argyrea* and *Pearcei*, pretty creeping plants with handsomely-marked leaves. *Panicum variegatum*, a Grass-like plant with striped leaves that grows freely. *Pellionia Dayana* and *pulchra*, free-growing creepers with dark olive-green leaves more or less mottled. *Pilea muscosa*, a Fern-like subject that will grow in a warm house, and also in a cool one. *Tralescandia zebrina*: The quick growth of this combined with its prettily-striped leaves renders it a general favourite for clothing the ground beneath stages and for similar purposes.

Of Ferns likely to suit you may be especially mentioned:—*Adiantum cuneatum*, *Blechnum occidentale*, *Davallia bullata*, *Nephrodium molle corymbiferum*, *Niphololus lingua*, *Pteris cretica*, *Pteris cretica albo-lineata*; and of the Moss-like *Selaginellas* there are:—*S. caesia*, *S. Emeliana*, *S. Kraussiana* (*S. denticulata* of gardens), and *S. Kraussiana aurea*. Next along the edge that is free from drip you may, if you like, plant a row of seedling *Streptocarpus*, which will do fairly well in such a position, and their flowers serve to lighten up the other subjects.

In house No. 2 much the same plants will be available, except that the drip will be detrimental to the *Streptocarpus*.

For house No. 3 a hardier class of plants is needed, and of these the following should suit you:—*Farfugium grande*, a plant with Colts-foot like leaves, rich green, spotted yellow; *Ficus repens* above mentioned

Isolepis gracilis, forms a tuft of beautiful green Grass-like leaves; *Stenotaphrum glabrum variegatum*, a rapid creeping Grass, rooting at every joint, with white striped leaves. Of Ferns, *Cyrtomium falcatum*, *Doodia aspera*, *Lastrea decomposita*, *Lastrea lepida*, *Lastrea varia*, *Platyloma rotundifolia*, *Polystichum setosum*, *Pteris serrulata*, *Pteris serrulata cristata*, *Pteris umbrosa*, and *Pteris Wimsetti*. The creeping *Selaginella Kraussiana* above referred to will also do well in the greenhouse.

NOTES AND REPLIES.

Nerines and Vallotas (C. S.).—I

your *Vallotas* and *Nerines* are going to flower this season they should be by now showing their spikes. The *Vallotas* never need drying to the extent of the *Nerines*, hence you may safely water them; but we scarcely know what to say about the *Nerines*, for, as a rule, the safer way is to wait till their flower-spikes appear before giving any water. Briefly summed up, the treatment *Nerines* need is this: They flower in the autumn, and then start into growth, after which they must be placed in a good light position in the greenhouse and kept watered, for they continue to grow throughout the winter and spring months. They need no shade whatever, and directly the leaves turn yellow and show signs of going to rest—generally in May or June—less water must be given, and finally discontinued altogether. The best spot for them then is in a sunny frame with plenty of air, but lights to keep off the rain, or on a shelf in a glass structure, fully exposed to the sun. Directly the spikes make an appearance the soil must be watered, when the flowers will develop rapidly. If shaded when in flower, the blooms will last much longer than would otherwise be the case. If yours show signs of the leaves starting without any flower-spikes, it is very probable you will not get any blooms this year; but another season, if you proceed on the lines detailed above, you may reasonably anticipate a good display. If no spikes or young leaves appear, we should advise you to wait till the end of September before watering your *Nerines*.

Plants for small unheated greenhouse (*Miss E. K.*).—If you need as early a display of flowers as possible in your unheated greenhouse, the principal things you can obtain are hardy bulbs, for such things as *Hyalocallis*, *Tulips*, *Scilla sibirica*, *Narcissus* of different sorts, and similar subjects will all flower well in such a structure, and anticipate the usual season of blooming out-of-doors by a sufficiently long period to make yours thoroughly appreciated. Again, a few other hardy plants (not actually bulbs) that are often grown for forcing readily lend themselves for flowering under glass, particularly *Spiraea japonica*, *compacta multiflora*, and *astilboidea*. *Dielisya spectabilis*, and *Lily of the Valley*. Small shrubs, too, can be recommended, such as *Ilex gracilis* and *D. Lemouinei*. Hardy Azaleas of different kinds, *Prunus sinensis flore-pleno*, and *Spiraea confusa*. Of hardy foliage plants you have but little choice, unless it be a few of the hardy Ferns. Throughout the summer you could keep your greenhouse gay at very little expense by consulting the advertising columns of *GARDENING*, for many collections are sent out at a cheap rate, and if these are carefully attended to in the matter of potting, watering, and tying they will flower throughout the season. *Lilium longiflorum*, too, grown in such a structure will, about the end of May, unfold its silvery trumpets, and later on you may have *L. auratum*, while *L. speciosum* bridges over the time between some of the summer plants and the *Chrysanthemums*. A few of the last with the scarlet *Salvia splendens*, the blue *Salvia azurea grandiflora*, and the latest *Cannas* will flower as long as you can reasonably expect any in an unheated structure.

Freessias for winter.—In considering bulbs suited for indoor growing for supplying blossoms in winter and spring, it seems only natural that one should regard *Hyalocallis*, *Tulips*, *Narcissus*, etc., as indispensable where brightness and variety are wanted; but too often, I apprehend, we forget such useful subjects as *Freessias*, which are not the tender, heat-loving things many suppose. Their fragrance and beauty are admitted by all, but few

really understand that the conditions of a house where Zonals, Salvias, Primulas, etc., are bloomed in winter will meet all that these charming bulbs need. From the middle of July to the end of August is really the best time to pot them, and a compost of loam and leaf-soil, with peat and sharp sand, will suit. Drainage must be ample, as they cannot bear removal, and consequently must be grown from the commencement in the pots in which they are intended to flower. Two bulbs will suffice for a 3½-inch pot, and a cold-frame until the middle of September should be reserved for them, covering with ashes until foliage pushes through, after which their removal to a house should be arranged. In the matter of watering one must be guided by circumstances as to heat of house, etc., as too much moisture will soon turn the foliage yellow. On no account should repotting take place, as the roots, being very brittle, quickly break. Stimulants may be given, and weak liquid-manure will help them. In spring after flowering watering should be discontinued gradually until it may be withheld altogether, and the bulbs left in the pots until started again next autumn. — WOODBASTWICK.

CORDYLINA AUSTRALIS IN FLOWER.

This stately, almost tropical-looking plant has been in cultivation in the milder parts of Great Britain and Ireland for many years, and, when strong and old enough, it frequently blooms, bearing one or more large, densely-branched panicles of small whitish flowers, as shown in the annexed illustration. It is nearly hardy, but a severe frost will damage the half-developed leaves, the very young ones, which are enclosed in the cone of older ones, usually escaping. This can, however, be easily prevented by tying all the leaves up into a bunch, the outer ones protecting all the rest.

AN EXCELLENT COUNTRY EXHIBITION.

The horticultural world will always be indebted to its enthusiasts, as it is by their persistent overcoming of obstacles that many of the greatest successes have been achieved. It is astonishing what one man may accomplish for a neighbourhood, and instances of this kind are frequently in evidence. A notable instance is that in connection with the establishing of an annual exhibition at Charlbury, in Oxfordshire. Two years since Mr. H. W. G. Morris, an enthusiastic amateur gardener, who has made for himself quite an enviable notoriety at Thame, in the same county, migrated to Charlbury, and chiefly owing to his indefatigable efforts a show of flowers, fruits, and vegetables was instituted, and repeated on Thursday, 28th August last. Increased accommodation was provided, and all available space occupied with an excellent representative display. Cut flowers were staged in good form and excellent condition—much better, in fact, than one might expect considering the peculiarities of the present season. Annals are generally well done at country shows, and at Charlbury they make the most of them. Asters were staged in profusion, classes for each type being provided. Sweet Peas were much better than they are usually seen so late in the season. Zinnias, and collections of six and eight bunches respectively of annals distinct, show how highly these densely-grown

flowers are regarded. The bunches were large and handsome, and contained French and African Marigolds, Godetias, Sweet Peas, Nasturtiums, Petunias, Spiral Candytuft (very fine), Ten-week Stocks, annual Chrysanthomums, Nigellas, China Asters, and other subjects. Fruit was well shown. Plums, Pears, and Apples, each judged for flavour, were a praiseworthy feature, as were also those for culinary purposes too. One large tent was almost exclusively devoted to the display of vegetables, and these were of a high order of merit and thoroughly representative. At Charlbury, like many other places in the country, the Potato disease was very prevalent, and a large proportion of the best tubers in the garden could not be used for exhibition purposes. The large gardens of the neighbourhood contributed their quota of interest to the exhibition. Their display of fruit was very fine, Grapes, Peaches, Nectarines, Apricots, Plums, Melons, Figs, Pears, and Apples being largely in evidence, giving their less favoured competitors a standard to which they might

which one may propagate. Many of these growths can be pulled off, and, as some of them have roots attached, they will go ahead and make nice sized plants before winter sets in. It is of little use to expect Pansies to furnish cuttings whilst they are full of blooms, and it is almost worse than useless to utilise stems carrying blooms as cuttings, for in most instances it will be found that they are hollow. The best plan, therefore, is to stop them from blooming, pinch out the leaders, which will at once cause shoots to spring from the base. If the weather should prove at all dry, the plants should be kept well watered. Cuttings got in by September will make well established plants by November, and bloom well another year. A bed made up in the garden should have some sharp sand or road-scrappings dug in before the cuttings are put in, and then a hand-light placed over all to prevent flagging. —TOWNSMAN.

CHRYSANTHEMUMS.

EARLY-FLOWERING CHRYSANTHEMUMS.

By mid-September at the very latest the plants in this section should be housed, and if many are grown the house should receive a thorough clean-out, by scrubbing woodwork, glass, etc., with hot water and soap, not forgetting to go into all the corners, where insect life is invariably found. The pots also should be cleaned before taking them inside, and any decayed foliage removed. These little attentions go a long way in making a house of 'Mums a credit to the grower. I think a good batch of these plants should always be grown, because there is a lull at this time of the year, the Geraniums, Fuchsias, Begonias, etc., being on their last legs, and therefore the early Chrysanthemums are almost indispensable, being both useful and offering also a distinct change in the house. There is a great deal of beauty about these plants when allowed to grow naturally; they require no staking and bloom most abundantly. There are now a great many new varieties on the market, some of which I have tried, but I always stick to a few old sorts, such as G. Wernig, Mrs. Hawkins, A. Dufour, Lady Fitzwygram, Mme. Marie Masse, and last, but by no means least, Mme. Desgrange. The Pompon section of this class are also very pretty and useful, and good varieties, such as the following, do extremely well, requiring just the same treatment as the foregoing:—Alice Butcher, red, shaded orange; Miss Davis, pink sport from Mrs. Cullingford; Toreador, crimson; La Vierge, pure white, large; California, bright yellow; and Mrs. Cullingford, pure white, and an exceedingly fine bloom. There are many others equally as good, names of which may be found in any Chrysanthemum catalogue. D. G. McL. *Bridge of Weir, N.B.*

Cordylina australis in bloom. From a photograph sent by Mr. J. A. Jones, 135, St. Stephen's Green, Dublin.

attain. The table decorations were particularly charming and simple. The first prize was awarded to a display of the pretty little blue Harebell, with just a few plumes of some of the finer Grasses. The whole thing was very simple, yet distinctly dainty. The second prize combined Sweet Peas in a pleasing blend of colours. A very large and totally unsuited display of La France Roses was put out of court, as the idea in its arrangement precluded its use on the dinner-table. For a sideboard decoration, however, it would have been superb. The only adjuncts to the flowers were long and graceful sprays of Rose foliage, which was a very handsome accompaniment. Farm produce, in the form of Turnips, Swedes, and Mangold Wurzels, was arranged on the Grass outside the tent, and these were freely staged and splendidly represented.

An effort such as this proves what one enthusiast can do in an out-of-the-way place in the country. D. B. C.

Pansies.—No time should be lost in cutting back Pansies in order to induce them to throw up short growths from the base, from

Japanese Chrysanthemums.—If exhibiting is a point to consider, it is wise to place the Japanese varieties in a house by themselves, so that more fire-heat can be given them during the time the blooms are developing, as these better develop the florets under the influence of a little artificial heat. In all cases place the plants as near to the glass as possible, so that they may have the full benefit of the light. The colours of each are by this means brought out in truer character than they can be where the light is diffused. The flower-stems also do not become drawn up weakly as when the plants are far from the glass. If the peduncles are weak it is an indication that the flowers will not be good, except, of course, where the variety is characteristic in this respect.

Chrysanthemums—staking and tying.—We have just experienced a serious gale which lasted two days, and which tried these plants exceedingly. I had, therefore, a good opportunity of noting how the various plants fared, and how much damage was done in the way of stems snapping off. Where a large number are grown there are sometimes two or three at the tying process, and each man has his own way of doing so. In looking over some hundreds I find that where plants had four stakes inserted round the edge of the glass with a piece of Raffia round the stakes at intervals, and the stems in no way

ted, but encased between the four stakes and allowed play, there is not a single case where the shoots have been damaged. It is therefore easily seen that support in the manner described seems to be the best preventive of damage to the shoots by storms of wind.—D. G. McL., *B. of W., N.B.*

Annual Chrysanthemums.—Though we have entered upon the season when the most popular sorts of Chrysanthemums bloom, it is pleasant to record, in a summer in which dullness has predominated very much, and we have had a deal of wet weather, that the annual Chrysanthemums have again helped to make borders very gay and supplied quantities of flowers for cutting. Prominent amongst them is the Corn Marigold (*Chrysanthemum segetum*), whose golden-yellow blossoms are useful for vases, and the tri-coloured sorts like Lord Beauconsfield (crimson, edged yellow), W. E. Gladstone (rich crimson). Coronarium aureum and album, double yellow and white-flowered sorts respectively, are well adapted for cutting. All these will grow in the poorest soils, and may be sown in the open.—WOODBRISTWICK.

GARDEN PESTS AND FRIENDS.

Ants (*Thomas Harris*).—You ask for a remedy to get rid of these pests, but we are not sure we can accommodate you. Powdered arsenic with white sugar (castor) is good, as they eat it and are destroyed quickly and in large numbers. Such a thing would require to be so placed as to form a trap and yet be where it would remain dry. A little could be placed in a flower-pot, covering the top and just giving admittance by the bottom hole to the ants. Large numbers are to be attracted to one spot by placing an inverted flower-pot over or near the run. They will be sure to congregate inside, and a kettle of boiling water will dispose of hundreds. A few such traps will quickly diminish their numbers. The nests are often found at the side of a lawn. This year the pest has been unusually troublesome, as we know full well. We usually adopt some of the above ways of lessening their numbers, and when constantly hunted they not infrequently depart. The soot, etc., used in a neighbouring garden must have been intended for another purpose.

The Codlin-moth.—In your issue of 30th August, 1902, p. 338, an answer is given to F. G. Dutton, recommending greasy hands to be put round fruit-trees as a protection against the attacks of the Codlin-moth, as they prevent the females from getting on to the branches. There is some mistake about this. The females of the Winter-moth (*Chimotobia brumata*) may be deterred in this manner, as they are wingless, but the females of the Codlin-moth (*Carpocapsa pomonella*) cannot be caught in this way, as they have wings and fly well. The caterpillars of this insect, when they leave the Apples, at once endeavour to find a sheltered place where they can become chrysalides, and for this purpose frequently creep up the stems of the trees until they find a suitable place in the bark. In order to assist them in these endeavours, bands of hay or straw, or strips of sucking, etc., 8 inches or 10 inches wide and long enough to go round the tree, should be folded lengthwise, and then again, so as to make the second fold about 1½ inches wide. It should be tied round the trunk with the folds uppermost, about 6 inches or a foot above the ground. The caterpillars in crawling up the stems find these very convenient shelters all ready for them, and become chrysalides in them. The bands may be examined from time to time, and any caterpillars or chrysalides found in them destroyed. The bands should be placed in position as soon as any "windfalls" begin to fall, and should be kept in position until the crop is gathered, and the "windfalls" should be collected as soon as they drop, and if stored should be put in a place from which the moths cannot escape.—G. S. S.

As many of the most interesting notes and articles in "GARDENING" from the very beginning have come from its readers, we offer each week a copy of the latest edition of either "STOVE and GREENHOUSE PLANTS," or "THE ESCALON FLOWER GARDEN," to the sender of the most useful or interesting letter or short article published in the current week's issue, which will be marked thus *.

VEGETABLES.

GIANT ONIONS.

The frequent heavy rains and cloudy weather, causing the soil to become cold, are not this season favouring the swelling of Giant Onions raised from seed in the winter and planted out at the end of April. That the bulbs like ample warmth, especially sun-heat, allied to liberal manure waterings, there can be no doubt. They swell more rapidly, they are firmer and keep better, and become less thick necked. There is one feature of Giant Onion culture which has impressed me this season. It is that anyone having a fine stock and planting the best bulbs annually to produce seed, may yet be wrong to continue sowing from such strain for more than two or three years, and find it wisest to obtain seed of a good stock grown elsewhere for a change. Naturally, those who have a fine stock are loth to lose it or to trust to the getting of one equally good elsewhere. But it is wise to do so to some extent all the same—risking something, yet at the same time growing some bulbs from one's own strain. It would be a good plan to co-operate with a good grower at some distance who has diverse soil and exchange seed yearly with him. If that be not practicable, purchase from a good seed firm, but stipulating that the seed supplied be grown remote from yourself. Really fine Ailsa Creig, Cranston's Excelsior, A 1, and other superb Onions can be had if sowing be made on fairly good ground during the last week in August, plants being dibbled out 12 inches apart on rich soil in April. A few may bolt, but the bulk will bulb well, and such ones are at summer exhibitions very superior to any of the Rocca or Tripoli section. The finest bulbs if later and good keepers are those of the same fine varieties sown in shallow pans or boxes under glass early in January, then dibbled outdoors into good ground in April. A. D.

NOTES AND REPLIES.

Blind Cabbage-plants (*G. W. J.*).—Blindness amongst Cabbage-plants has been very uncommon this year, because abundant rains have caused quick growth. Whilst it is difficult to define the real cause, as sometimes it is thought to be due to insects, sometimes to a fungus, sometimes to cold, and other causes, we are disposed to think in your case the primary cause is too thick sowing, as we observe the plants sent are unduly water-logged and drawn, evidently having been too crowded in the seed-beds. Crowding is best avoided by sowing thinly in shallow drills, from 10 inches to 12 inches apart, as in that way the plants get ample room. They should not be allowed to become dry or meet with any check. You would, no doubt, find that free dustings with soot over night and good overhead waterings next morning would check any insect attack. Do that twice a week, till the plants are pulled for planting out.

Asparagus.—How seldom is Asparagus seen grown in cottage gardens or on allotments, except on elevated beds and in a very small way. If small growers could but see the very fine growth now found on beds that are comparatively flat, as is the rule to grow Asparagus in large gardens, they would note how relatively unsuitable is the raised bed system. Recently I saw growths on plants but two years from seed that were 6 feet in height and proportionately stout of stem. These plants were growing where sown in rows 2½ feet apart, and thinned out in the rows to 2 feet apart. The gain found in sowing where to remain permanently is very great, as the plants get so well established early, and are usually a full year in advance of those transplanted. The ground, before it is sown, should be deeply trenched, heavily manured low down, and also mixed with the top spit; also should have forked in the following year bone-dust and guano, and get during the summer liberal soakings of liquid-manure.—A. D.

Pea Gladstone.—Autocret, hitherto regarded as one of our very best late Peas for exhibition, seems now to have been displaced by the long, sword-shaped Gladstone, which, in a fine sample, contains ten Peas in a pod. That is, I believe, the maximum number found

in the pods of any variety so far. The pods and Peas are green, and, when cooked, of delicious quality. It is odd, but no one seems able to state who was the raiser of this fine variety. In the great competition at Shrewsbury Gladstone took the highest positions. Some of the leading vegetable exhibitors, in their collections, had included large pods of tall Peas of the Duke of Albany type, but these were all rather puffed, and when pressed on the sides were found to be soft, also opening badly. Free or easy shelling is a feature in Pea judging that should have due weight, as it is most annoying to find pods break in the hand rather than open freely. Gladstone Pea is of medium height, from 3 feet to 3½ feet, and is a heavy cropper. If sown early, it naturally succeeds the midseason varieties.—A. D.

Seed Potatoes.—Now that the work of lifting and storing this year's crop of Potatoes is one of the most pressing needs in the kitchen garden, it is a good time to make comparison of the returns in weight from home-saved seed and those that have been imported from fresh stock and different kind of soil. I am no advocate of buying everything that is new because it is well advertised, but I thoroughly believe that an entire change of one's seed Potatoes is rooney well laid out. In this locality we have some large growers of Potatoes who supply the barracks and the Fleet with many hundreds of tons, and I find that if there is one point on which they are unanimous, it is as regards a change of seed being of more importance than any other item of culture. On the South Coast the seed that is most largely used is that which comes direct from Scotland or the northern English counties. I need hardly say that amongst early Potatoes there are few that have held their ground so long as the Beauty of Hebron or American Rose, for it yields a heavier weight of tubers in June than any kind of Kidneys, but there are some excellent new kinds that are likely to supersede all these old favourites, and amongst long-keeping sorts I do not think any kind has been so largely or satisfactorily grown to yield heavy crops of handsome tubers equal to Up-to-Date. But in all probability the march of improvement will go on as long as Potatoes are required for food, and whether it be market growers or the smallest cottage gardener in the land, it is as well to discard at once the notion that any kind of tuber not fit for cooking is good enough for seed, for a good deal of the success of one's work depends on the kind of seed used.—J. G.

LAW AND CUSTOM.

Tenant's right on removal.—Can the tenant on a yearly agreement of a private garden legally remove trees planted by himself on the completion of his tenancy?—*Enox.*

[No, he cannot. This is evidently a question on which much misconception exists, for it is one we are very frequently called upon to answer.]

Tenant removing plants (*H. H.*).—The occupier of a private garden may not remove any plants, neither can he claim compensation for them. This may be a very hard thing, but it is law. Usually, a landlord allows an outgoing tenant to take some of the choice plants away, and you should ask your landlord to extend the same courtesy to you; but he may refuse if he chooses.

Claim to a vinery (*B. T. T.*).—According to your letter, you held some property on a lease and erected a vinery there. Subsequently you sub-let or assigned your lease, with the assent of your lessor, to a third person, who agreed to pay you a specific sum for the vinery and for other improvements. The landlord joined in the transfer of the lease, and you gave up possession, and also, it appears, received a part of the sum arranged to be paid for the vinery. Subsequently the lessor, you say, claimed the vinery to be his own because it is attached to the freehold, and your assignee refuses to pay the balance of the agreed sum, and you ask if you cannot now remove the vinery. You cannot do this, as you have parted with your interest in the property, but you may sue your assignee or transferee for the balance due on the contract between you. It is somewhat doubtful whether your lease was not actually surrendered to your landlord, but, as the assistance of a solicitor will be necessary in any proceedings you may

take against your successor, the solicitor will advise as to the precise form your action should take.—K. C. T.

A partnership question (A. B. C.).—Seven months since you entered into a contract with your employer to serve him as head gardener and to share (apparently equally) in the profits of the garden. A written agreement was entered into, securing to you, in addition to a share in the profits of the business, a weekly sum of wages, a house, coals, firewood, and vegetables, your employer also contracting to feed you in each year one fat pig weighing not less than 25 stones. The business was carried on in your name, and printed circulars were sent out, and business memoranda used upon which your name only appeared. Your employer now wishes you to give notice to determine the contract, and you ask if it would be wise for you to give such a notice; but this is a question I certainly cannot answer. If the business is profitable I suppose it will not be wise for you to give it up, and you should let your employer give you notice. It will then depend upon the terms of the agreement whether the notice given be good or not, and it may be a moot question whether you are a servant or a partner, although I think you are not a partner.—K. C. T.

A gardener's notice.—I engaged a gardener, single handed, without any stipulation as to notice to determine the contract. He commenced work on Tuesday, August 19th, and on Saturday, the 24th, asked for payment of wages, and I told him I would pay him on Tuesday, when his week would expire, and that in future I should pay him fortnightly. As, however, he explained he was in need of money, I paid him five days' wages. He did not suit me, and on Friday, the 15th of August, I told him I wished him to leave on Tuesday, the 19th, at the end of his fortnight, but he said he would have a week's notice. On Saturday, the 16th, I gave him written notice to leave that day week, and he replied in writing, "Your notice of 6 days is not necessary. I have already taken your notice yesterday to leave to-day, claiming a week's wages; if you object to that I shall proceed against you." I had said nothing to him about leaving on the Saturday. I had said him to go on the Tuesday following. On the Saturday night he asked me for a week's wages, which I paid him. He came on the Monday between 10 o'clock and 11 o'clock, and asked for a week's wages, but I did not see him. He left word that if I did not pay him within seven days he should take proceedings. What is my position?—AN ANXIOUS ENQUIRER.

Presumably the man was engaged at a weekly wage, and, if so, his wages were payable at the end of the week of service, and not before. You might, therefore, have refused to pay him until Tuesday, but, to oblige him, you gave him five days' pay on the Saturday. You could not, in the absence of an express stipulation or arrangement, pay him fortnightly, and if you wished the week of service to continue to end on Tuesday you should have paid him two days' (or one day's) pay on Tuesday, the 12th. But I do not see how you could expect the week to end on Tuesday if the man commenced work on Tuesday, for in that event his week ended on the Monday night. Let this be as it may, you did not pay him again until Saturday, the 16th, when you paid him a week's wages, and so it is evident that, formally or informally, the duration of the week was varied so as to expire on Saturday night. In the absence of any stipulation as to notice, a week's notice was at the least necessary, and the man was quite at liberty on Friday, the 15th, to refuse to leave on Tuesday, the 19th, and he was entitled to demand a week's notice, as he did do. You gave him a week's notice on Saturday, the 16th, to determine his service on Saturday, the 23rd, and you were perfectly right in so doing. The man's contract expired on the 23rd, and, as he left on the 16th without giving you proper notice, you can recover from him a week's wages for leaving without proper notice. His contention that he was entitled to accept your desire that he should leave on the 19th as a dismissal for the 16th, and that he would then be paid a week's wages in lieu of notice, is simply ridiculous, and I am surprised that you should have found it necessary to ask advice as to your position. Evidently you and your man have both of you peculiar views as to your powers and responsibilities. If I were in your place I should not wait for your late gardener to sue you, but I should sue him for a week's wages for leaving without first giving proper notice. You may, of course, think yourself well rid of him, and so may not trouble about him, but if he does sue you, you must certainly sue him.—K. C. T.

CORRESPONDENCE.

Questions.—Queries and answers are inserted in *GARDENING* free of charge if correspondents follow these rules: All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of *GARDENING*, 17, Finsbury-street, Holborn, London, E.C. Letters on business should be sent to the PUBLISHER. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper, and not more than three queries should be sent at a time. Correspondents should bear in mind that, as *GARDENING* has to be sent to press some time in advance of date, queries cannot always be replied to in the issue immediately following the receipt of their communication. We do not reply to queries by post.

Naming fruit.—Readers who desire our help in naming fruit should bear in mind that several specimens in different stages of colour and size of the same kind greatly assist in its determination. We have received from several correspondents single specimens of fruits for naming, these in many cases being warped and otherwise poor. The difference between varieties of fruits are, in many cases, so trifling that it is necessary that three specimens of each kind should be sent. We can undertake to name only four varieties at a time, and these only when the above directions are observed.

PLANTS AND FLOWERS.

Roses for boarded fence (J. Park).—A good crimson variety would be *Ards Rover* or *Forth Brunner*, and for a white one you could not plant a more beautiful Rose than *Mrs. Alfred Carrière*. The best time to plant is early in November.

Insects on Fern (S. B.).—The insect with which the fronds of the Fern you sent are infested is the brown scale, which can only be cleaned by hand. No insecticide strong enough to get rid of it can be used without at the same time killing your plant. Patience and careful attention only can keep your plant clean of such pests.

Gypsophila elegans (M. H.).—The *Gypsophila*, when established, though hardy, but small seedlings just above ground will be all the safer if wintered in a frame or cool-house, as an excess of rain is just as injurious to them as actual frost. Next spring they may be planted out, and the following winter will need no protection whatever.

Alostromerias in pots (Della).—Your seedling *Alostromerias* may be wintered in a cool-house or in an ordinary garden frame, as all they need is just protection from frost and from excessive moisture. At the same time they must not be dried up when dormant, but given just sufficient water to keep the soil slightly moist. It will be greatly to their advantage to protect in the winter and plant out in the forthcoming spring.

Asparagus Sprengeri (M. H.).—This is a native of South Africa, and like all plants from that region, it needs the protection of a greenhouse; indeed, where ground for sale more heat is generally given in order to obtain effective-sized plants in as short a time as possible. A suitable soil consists of two-thirds loam to one-third sand, with a little sand and some liquid manure or one of the many concentrated stimulants may be given when the pots get full of roots.

Carnations bursting (Norma).—The cause is chiefly with the variety, and is due in some measure to the shortness of calyx, the more or less bluntness of the calyx at the apex, and the great number of petals in the flower. Varieties with fewer petals and a longer, more uniformly-sized calyx are much more free from this bursting of the calyx. No culture can remedy it, but it is made worse by disbudbing, which naturally gives greater force to the flower-buds that remain.

Asparagus Sprengeri seeds (Northlands).—Gather the seed-berries on your *Asparagus Sprengeri* as soon as they part freely from the shoots, but not till then. Whether the seeds in the berries be fertile or otherwise will depend on their maturation, towards which a little warmth would help materially. Generally seeds grow very well here when ripe. Put the seeds into a box and well mix with quite dry sand. Keep in this condition all the winter, then in March mix with some loam, and sow in shallow pots or pans in fine soil, standing them in gentle heat in a greenhouse or frame.

Sweet Peas (A. T. Simpson).—There has been much trouble with the Sweet Peas this year by reason of their unevenness in various districts. It is, we believe, mainly due to the exceeding activity of the humble-bee last season in cross fertilizing the different varieties. Whether this is so or not, it is a very true that in a large number of instances this sportive character has been felt. At first it was regarded as want of care in the seed saving or some careless mixing up at harvest time. The many instances, however, that have come to light are far too numerous to admit of this being the only possible explanation.

Liliums (S. B.).—Bulbs of *Lilium speciosum*, *araucatum*, and *Harrisii* will, if properly treated, flower well next season again, but not longiformer. After they have done flowering this season, and the stalks have died down, the bulbs should be turned out of the pots and plunged outside in either loose sandy soil, or better still, in ashes or Cocoa-nut-fibre, and covered over with about 4 inches of the same material. They should be protected by mats or dew cloths against hard frosts in winter. To flower about mid-August they should be started about the middle of May, so as to let them grow naturally. It is best to start them in a frame or cold-pit.

Rose Crimson Rambler on a south wall (K. C. T.).—This is about the worst place one could plant this Rose, unless it is a low wall and there is a trellis above it. *Crimson Rambler* is a moisture-loving variety, and is very prone to attacks of red-spider, so that it should always be planted where abundance of air can circulate among its foliage, and its roots be supplied with plenty of moisture and good drainage. A trellis, pillar, gateway, stump of old tree, or any position in that line is the best manner of disposing of this brilliant Rose. A hedge of it makes a beautiful object if some Oak posts are let into the ground and some wires stretched at intervals and supported for a year or two.

Wallflowers (Suede).—It would appear that you made the first stop very early, or that in this instance, by reason of circumstances, a second pinching was necessary. When the flowering is desired in winter special means have to be taken, and the actual pinching of the shoots can only be determined by the progress of the plants and by the season. In the present instance a second stopping should have been made early in July. If you stop the shoots now the chances are there will be no flowering till late spring. You could, however, experiment with a plant, and presently lift and repot the batch, which may help to keep them in check. Taking notes of the progress of the plants is the best way of obtaining the requisite information in a special case like this.

Budded standard Briars (P.).—Supposing always the germ has not been removed from the bud, one can usually tell from the plump appearance of the eyes peeping through the binding that it has "taken," but to reduce the risk of unbudding too early, you should after three weeks unite the buds to prevent injury to the shoot, and re-tie them again immediately, but not quite so tightly as at first. The second tie may remain on all winter, and be a certain amount of protection to the buds. The first tie will not need a second tie, unless budded Briars, the first season unless really necessary. On referring to our back numbers you will learn exactly how to proceed with such Briars the first season. You can replant in November of the following year after budding.

Potting a plant (A.).—When a plant requires re-potting into a larger pot the old soil should not be shaken away from the roots, but merely the old drainage material be taken away, and a very little of the old soil removed from the top of ball of roots. The plant is held in position in the centre of the pot by the left hand, whilst the soil is placed round its roots by the right hand. The pot should, of course, be drained first, and a little rough material be placed over the drainage before the plant is put into the pot. The soil should, generally speaking, be pressed down rather firmly around the roots, and sufficient space—say an inch—should be left below the rim of the pot to hold water when required.

Climbers for a small stove (B.).—We should imagine the place in question does not require a very large growing plant, and few things better suited to the lovely small-flowered and neat-growing *Aristolochia elegans*. This is small-flowered for one of this genus. Its blossoms are produced freely and continuously, and they are quite destitute of the disagreeable odour peculiar to many of the species. The flowers are very beautiful, the ground colour being creamy-white, which is nearly covered with rich velvety dark purple, the throat being golden-yellow, round which is a continuous band of deep velvety purple. It is a showy plant, growing well potted in rich loam, peat, and leaf-mould, made tolerably gritty with sand, the pots being well drained, and a liberal supply of water given.

Sample of garden soil (Spade).—The soil is of fairly good quality, but the results obtainable depend very materially also upon the amount of it at the disposal of the roots, and particularly the depth. If the latter is of an average of 2 feet, you may, with good culture, grow many things quite well. The first thing to do is to have the entire set of borders trenched without delay, and give a heavy dressing either of cow-manure or of well-rotted horse-manure that has been some time in the heap. In digging in the manure, take the precaution of keeping it down, say, 12 inches below the surface. In this way the lower soil is enriched, and the roots are encouraged away from the surface. For Roses and many herbaceous plants a rich—i.e., more or less heavily-manured—soil is necessary.

Fuchsia fulgens (E. F. H.).—The leaves of your *Fuchsia* were much shrivelled on reaching us, but they appear to have suffered severely from the attacks of small yellow thrips, quite a microscopic insect, which was comparatively unknown till a few years ago, since when it has greatly increased, but, owing to the close and proper summer care it has not, in most gardens, at least made so much headway this year as it did during the last two or three preceding ones. The mischief is done while the leaves and stems are very young, so that by the time the condition of the plant is evident it is often impossible to find any thrips thereon. The most effectual remedy for these pests is vaporising with the XL All Vaporiser, but even then it needs to be done two or three times at intervals of about a week in order to destroy the eggs as well as the perfect insects. Syringing with any of the numerous insecticides will also accomplish the same end, while the best of the home-made remedies is strong soap and water, applied wetly with a syringe, taking great care to thoroughly wet the undersides of the leaves.

Sanchezias (Sumeret).—*Sanchezia nobilis variegata* is a native of Brazil, and in this country needs the temperature of a stove for its successful culture. Indeed, the conditions suitable for *Crotons*, except that it does not need so much direct sunshine, will suit it well. Given proper facilities, it is not at all difficult to propagate from cuttings of the young growing shoots in the spring. They should be about 4 inches long, taken off at a joint, the bottom pair of leaves removed, and then inserted singly into small, well-drained pots, filled with light sandy soil, such as equal parts of peat, loam, and sand. Then plunge the pots in a close propagating-case in the stove, where there is a gentle bottom-heat, when the cuttings will soon root, and must then be hardened off to the ordinary atmosphere of the stove. During the summer months this Sanchezia may be kept in a greenhouse, provided it is shaded and gets but little direct draught. A mixture of equal parts of loam, peat, and leaf-mould, with a good dash of sand, is a very suitable potting compost for it.

Redning growths of Rose Polyantha grandiflora (W. M. Cooper).—This is probably one of the most vigorous of ramblers, and is a fine variety where unlimited space is at one's disposal. But, as you say, its tremendous exuberance of growth will quickly smother other good things. Your best plan will be to cut away at once about half of the number of growths, retaining those well matured, and, if possible, having some laterals. We had a plant of this Rose last season growing in the open border, and one large growth being allowed to arch over produced a number of laterals that yielded fine trusses of blossoms. This one growth alone was a perfect picture, so that you may even reduce the number of growths to one or two, provided they are well

hardened. Each season, as the numerous sucker-like shoots appear, reduce them to about two in their earliest stages. Such growths as you leave for flowering should be left unpruned beyond shortening back each of the laterals to about 3 inches or 4 inches. These main growths, by suppressing the laterals, will be induced to lengthen, supposing they pass through the winter safely, for we have found this Rose somewhat tender, which proves it to be not a variety of *R. multiflora*, or, at least, it is making of the Tea or Noisette blood in it.

Making Carnations and Stocks flower about same period (*Charlie Cubley*).—This query is somewhat difficult for us to understand—at least, in the way you put it. You say your plants never have many flowers at one time. In the case of the Carnations, the leading bud on each plant opens first, and this is followed subsequently, and in proper order, by the buds on the side shoots or lateral growths. You cannot get the whole of the blossoms to open at one time. Varieties of Carnations also differ in their period of flowering; some are early or mid-season, and some are late in their blooming. The only thing you can do is to obtain varieties which blossom about the same time. The same rule also applies to the Stocks referred to by you. The largest head of blossoms on the main growth usually opens first, and this is followed by the lateral shoots developing around it. In this case, however, you may achieve your object by pinching out the point of each of your plants when they are some 6 inches or more in height. This manipulation of the growth will cause the plants to break out into quite a number of vigorous side shoots, which in a normal season should come into flower at the same time. If you pinch your plants in this way they should make good sturdy specimens. We very much doubt whether you could do nearly as well with plants of a weak or spindly character.

TREES AND SHRUBS.

Wistarias (*G. B. Scott*).—If lifted from the ground and late planted, the Wistaria often behaves in the manner stated, the stems retaining some signs of life, yet the plants remaining inactive. It will be best to plant fresh, and to be content with young growing plants 3 feet high or so. Plant any time in September if possible, or leave it until the end of next March. Try to obtain your plants established in pots. Ask request their delivery in this way. It is a plant not suited to endure undue exposure or rough treatment.

Shrub (*H. M. Stanceley*).—There are several species of *Elaeagnus*, but *E. longipes* is certainly deciduous, not evergreen. *E. macrophylla* is a good Irish plant, and so also are *E. reflexa* and *E. glabra*. *E. angustata* is practically an evergreen. Any of these are worthy, and of course also there are variegated. Varieties of the *Weigela*s are good, and the Mock Orange (*Philadelphus*), but these are deciduous. If you can command a light, well-drained soil, *Garrya elliptica*, when loaded with its long, creeping catkins, is a most attractive plant and a good evergreen.

FRUIT.

Gathering Apples (*T.*).—It depends very much upon the season as to the time for gathering. If any Apple is gathered before reaching ripe the fruit shrivels. A good test of ripeness is to pick a fruit from the most shaded part of the tree, cut it open, and if the pips are brown all the crop may be safely gathered.

American-blight on Apple trees (*Postum*).—Your trees have been attacked by American-blight. Get a little paraffin and wash it in where the insects are. A little later wash them out with clean soapy water, then mix a little soap, clay, and paraffin into a paste, and well daub it into any of the cracks where the insects may be. If any appear later, treat them in the same way.

Falling Nectarines (*H. E. T.*).—You do not say how your Nectarine-tree is being grown. Is it inside a house or on a wall, and, if the latter, on a south wall? Possibly in County Cork, because of the prevailing dampness, the flowers were imperfectly fertilised. Perhaps some fungus or mildew has affected the tree; there is no evidence in the soil, nearly rotten fruit sent of such mildew, but there may be on the leaves. Probably your best course would be to open the soil down to the roots, and to replace it with fresh loam, adding a good proportion of old mortar, lime, wood-ashes, bone-dust, and just a little old hot-bed manure. It is difficult to prescribe a remedy on such slender information.

Forcing Vines (*J. C. Cork*).—It is perfectly safe for you to force the whole of your Vines in your house at the same time, it does not matter whether the roots be inside or outside. But before you begin to force cover over the outside border with dry leaves, 3 inches or 4 inches thick, to keep out frost, or with Fern or long straw litter. Also specially be careful to put your hands over the stems of the Vines that are outside, so that frost does them no harm while being forced. Of course, you may lift those outside Vines and bring them inside if you can; but how would you get the rods through the holes in the wall? If you do succeed you must cut them back hard and allow them to carry new rods only the first year. They would not be fit to put so soon after being lifted and repanted.

Figs in pots (*G. E. K.*).—As your Figs in pots are doing so badly, probably they need repotting. Your course would be to get pots fully 2 inches broader than those the Figs are now in; also some good turfy loam, adding one-fourth of well-decayed hot-bed manure, some bone-dust and soot. When you turn the plants out of the pots remove some of the old soil and the drainage, then put them into the fresh pots, which must have been well crocked or drained first. Pot very hard. Figs under glass need frequent syringings and occasional dampings of the floor of the house. It is quite easy to understand that your plants are suffering both from poorness of soil and root dryness. Repot as soon as the leaves fall.

Grapes splitting (*Wyndhamham*).—We presume that the roots of your Vines in an unheated greenhouse are in an outside border, and necessarily have this season been more than usually moistened by the heavy rains that have fallen. That alone would suffice to cause coloured Grapes to split as yours have. The border needed some cover to partially throw off the heavy rains as soon as the Grapes begin to colour. Then we have had so little of sun-heat, and as a consequence the kind of the berries grown without heat have been thin, and used as they are

more susceptible to injury when an excess of moisture at the roots created a sudden rush of sap into the berries. It is thus seen that the trouble you complain of arises from very commonplace causes; but, like those, though so simple, are often difficult for the amateur gardener to understand.

Fruit-trees on south fence (*M.*).—Your wood fence 6 feet in height that has been tarred is not a nice place to hope to grow fruit well. Trees do not like tar, and if the sun warmth should soften it on the boards at any time, it would be offensive. However, you may plant an Apricot, a Royal George Peach, an Elrige Nectarine, a Green Gage Plum, and a Marie Louise Pear. Six feet is a low height for training trees to. The lower branches should be kept well down, so as to fill the spaces. If in time the trees seem to make too gross growth, it might be needful to root prune the trees. They should be at least 10 feet apart.

Cordon Apple and Pear-trees (*H. M. S.*).—As no doubt, your galvanised iron fence is secured to stout uprights of wood, if you fix trellis, whether of wire or otherwise, to those uprights, the trees will be some 2 inches or 3 inches from the iron. There is no fear in such case they will be too hot. While it is always best to nail fruit-trees to walls, where the sun-heat and the stored heat is good for them, if close to galvanised iron fences the trees would be temporarily hot, but more often would suffer from great cold. Apples, as a rule, need to be in positions than Apples and Pears do, but they do not thrive well on iron fences.

Discoloured Vine leaves (*Puzzled Subscriber*).—The coloured marks seen on your Vine leaves are common enough on many varieties of Vines late in the summer, but especially so when so mild and unless as the past season has been. It is particularly easy to understand this discoloration showing itself on a Vine of the somewhat tender nature of Mrs. Pince's Black Muscat, which is evidently your variety. It needs a heated vinery to bring Grapes to perfection, and is always a difficult Grape for even the best growers to do. You should have in your cold-house either a Black Hamburgh or an Alicante Grape, as these will do well in such a house.

Gourds (*Uppermill*).—If you refer to the innumerable species of the Gourd family when you speak of "Gore," we can only say that there is no limit to either size or weight, and all depends on the grossness of the supplies of food and its amount; indeed, it is on the principle of cramming a turkey or a goose, in which the larger framed bird has by far the best chance. In several of the south and south-west counties the Gourds may grow to a great size, the actual size depending greatly upon an early start, no check to growth, constant attention to water and stimulants, a sunny position, and a deep, well-enriched soil. In that case it is possible—and in a soil quite new to them—to grow the fruit to an almost incredible size.

Peach-trees in pots (*J. R. G.*).—It is not at all difficult to grow Peach-trees in pots under glass, but it may be very difficult to do so successfully if the trees be in a greenhouse containing other plants. Fruiting Peach-trees should be some three or four years waked, and be in pots from 10 to 14 inches over. They require for chiefly turfy loam, with which are mixed a little well-decayed manure, some lime-rubbish, wood-ashes, and bone-dust. The trees need pruning in the summer chiefly, shortening side shoots. After they have fruited, the trees should be stood outdoors in the sun, kept well watered, and the pots shaded to ripen wood. General Peach culture in pots is successfully done only by very experienced gardeners and in glasshouses specially devoted to them. They need ample light and air and the most constant attention, or they soon become eaten up with aphid.

Orchard in Brass (*R. E. P.*).—We fear, with the overhanging standard Apple and Pear-trees planted some years since at but 12 feet apart, that the plants must be very dense and shut out light and air. To hope to obtain a ground crop the trees should be thinned out and the heads of those left also. The trees in such an orchard should be fully 20 feet apart, and if larger ones, then 30 feet apart. As at present it would probably be too dark for Gooseberries and Currants or Strawberries, but Raspberries, Rhubarb may do fairly well; or of flowers, Daffodils in variety or Wallflowers. Grass land is apt to contain a good deal of wireworm. If you open a trench at one end of the orchard, first paring off the turf 3 inches thick, then, forking up the bottom, pare off the turf 3 inches thick from the next trench, throw it in up-side down, then on that a good dressing of gas-tine and soot, then on that other 12 inches of soil, doing all the orchard the same way, you should grow things well.

VEGETABLES.

Potato (*H. C. S.*).—Your Kidney Potato is without doubt an Ashleaf. There are, however, various selections in commerce, all very much alike, and yours is one of them. The Ashleaf is early, flesh slightly yellow, and exactly the shape of sample sent. Although over sixty years in commerce, it is still one of the very best flavoured. Yours is an extremely nice clean sample.

Mushrooms (*A.*).—Nothing is more common than for Mushrooms to suffer from attacks of the maggot; you refer to during hot summer weather; hence in private gardens Mushrooms are seldom made up and spawned to come in during July and August owing to the exceeding dryness of the atmosphere. No doubt your bed has suffered from this cause generally; hence the smallness of the produce. Practically there is no remedy. You will do better if you make up beds now from properly prepared manure, either ridge-shaped outdoors or flat in a shed or cellar. Much depends, too, on the proper preparation of the manure, and then the fresh, well-spawned nature of the cake purchased to fertilise the beds.

Growing Cucumbers (*C.*).—The best way to arrange the wires for the trellis would be to fix permanently a stout iron rod at both ends of the house, about 18 inches from the glass, and strain wires from end to end horizontally, and to these tie the Cucumbers with soft raffa or matting. Almost any kind of wire will do, provided it be strong enough to bear the strain. Copper wire, about the thickness of stout lead, will do; and it might be taken down when the Cucumbers season well over and be used away till the following year. The wires should be about 1 foot apart from each other, and

should it be necessary to support a heavy crop of fruit they could be looped up in the centre to the rafters. We are supposing that the Cucumbers will be a temporary crop, and that at other seasons the wires would be in the way.

Uses of a hot-bed frame (*R.*).—A great many things may be grown in such a frame, but, of course, not without labour. Chrysanthemum may be forced in it early, and the roots should be taken out. Asparagus will force very well in such a frame. An early crop of French Beans may be had by planting in March; also Strawberries, either in pots, or the plants may be carefully lifted from the open ground with balls of earth, planted in the frame, and brought on gently at first. Tomatoes may be planted along the front of the frame inside, and trained over stakes or any kind of rough trellis, thinning and stopping the growths as required. In all cases success will depend upon the intelligence and perseverance brought to bear.

SHORT REPLIES.

C. Smith.—What has your employer to do with your garden? Are you occupant of a house and garden belonging to him and supplied to you rent free while you continue in his service; or do you rent a house from him; or is the garden, which you refer to as "my garden," one of which you, as gardener, have charge? It is a pity that querists who want information do not try to put themselves in the place of those who receive their letters, and realize the fact that it is necessary to supply full particulars if the advice given is to be of any value. We fear you have no right to remove the tool-shed, and you had better make the best bargain you can with your employer. **Ignoramus**.—Hobday's "Villa Garden," published by Macmillan, would be useful for your purpose well. Of course, if you cared to buy several books dealing with flowers, fruit, and vegetables separately, you would get fuller information, and gardening is now such a big subject that it is not possible to treat it all comprehensively in one volume. The best book on hardy plants is "The English Flower Garden." "Greenhouse and Store Plants" is an excellent work on this branch of the subject, and there is no fuller book on vegetables than "The Vegetable Garden." Each of these is bigger than Mr. Hobday's work, which is, nevertheless, an excellent manual. **K. J. M.**—The Fern you sent is *Nephrolepis pulchella*, and the Insect on it is "brown scale." The only way to get rid of the scale is constant attention and removing the scale with a stick or the finger nail. No insecticide will act effectively unless strong enough to injure the plant at the same time.

NAMES OF PLANTS AND FRUITS.

Names of plants—*W. R. Tvo. 1*.—*Thalictrum aquilegifolium*; 2, *P. C.*—*Mimulus tigrinus*.—*Achillea*. 1 and 3, *Quile* dried up when examined; 2, *Lycanthus maximus*.—*G. M. S.*—1, *Echinops ruthenicus*; 2, *E. sphaerophyllus*; 3, *E. comutatus*.—*H. D. P.*—*Mine*, Alfred Carrière. —*S. L. B.*—We do not name varieties of Roses and other florists' flowers, as this can be done only when comparison with a large collection is possible. It would, in any case, have been impossible to compare yours, for the flowers dropped to pieces as they were taken from the box. *P. C. Harrop*.—The bottom of the board box appears to have been lost in transit, and the plant disappeared. —*G. G.*—Species or variety of *Althea*, but we could not name it, so much as we would like to. *W. L.*—Looks like species of *Blitweed*, but the specimen was quite decayed. —*S. H. Wright*.—1, *Sent* again, quite decayed; 2, *Polygonum* sp.; 3, the plant you sent is an annual weed, too far gone for identification; it is certainly not a Dodder, which is a parasitical plant.—*Mrs. E. Leeds*.—1, *Chrysanthemum setosum*; 2, *Callipais bicolor atro-sanguinea*; 3, *Helianthus multiflorus* (Soleil d'Or); 4, *H. m. plenus*; 5, *H. (Harpalum) rigidus*. —*T. V.*—1, *Lysimachia clethroides*; 2, *Chrysanthemum latifolium*; 3, *Pyrethrum nigrosimum*. —*Tent Loly*.—*Veratrum nigrum*. The plant is sometimes known as "Pulse Hellebore." Of vigorous habit, requiring a good strong loam, and in such will thrive for years if not disturbed. The plant is most showy when kept in culture upwards of three centuries. —*Leeds*.—Ornithogalum, white; 2, *Isophylla alba*.—*Ernest Ballard*.—1, *Solidago virgaurea*; 2, *Sent* in flower; 3, *Veronica spicata* and *alba* mixed; 4, *V. Andersonii* *alba*; 5, *Helianthus grandifolium striatum*; 6, *Polygonum orientale*; 7, *Solidago rigida*.

Names of fruits.—*Bloxham*.—Apparently Lord Selkield; but we do not undertake to name fruit from single bruised specimen.—*R. F. C.*—The numbers on your Plums had got displaced in transit. The large red (No. 1 or 4) is Pond's Seedling; the oval green Plum is Gishorn. Both are cooking Plums, and have little of favour. Nos. 2 and 3 were too much decayed to enable them to be recognised. Fruit should not be too ripe when sent for naming.—*D. J. M.*—The four Pears sent, if for naming, are still far too immature to be correctly named, and corrected names are of no use. All the fruits were in a bag, but three weeks longer in the box they would be in their true form. In the heat, for the seeds are yet quite white and the flesh is very hard. Send a month later, and wrap each fruit with number in paper; do not trust to pins.

Catalogues received.—*Barr and Sons*, 12 and 11, King-street, Covent-garden. —*Hyacinths, Tulips, etc., and List of Gold Medal Dahlias*.

Photographs of Gardens, Plants of Trees.—We offer each week a copy of the latest edition of the "English Flower Garden" for the best photograph of a garden or any of its contents, indoors or outdoors, sent to us in any one week. Second prize, Half a Guinea.

The Prize Winners this week are: 1. Mr. Geo. E. Low, Dublin, for Royal Fern in garden at Mount Usher; 2. Mr. J. Rose, Oxford, for Laburnum Waterer's variety.

GARDENING ILLUSTRATED.

VEGETABLES.

CELERY.

There should be an abundance of good Celery during the coming winter. Whilst the plant does very well as a rule in hot weather, its growth is quite dependent on the moisture furnished to the roots. Still, Celery is a cooling plant, and generally quite hardy. It is best for consumption in a blanched state, when growth is quick, the stems being then solid and crisp. That condition cannot always be secured in hot weather, because any neglect tends to furnish ample moisture to the roots, and to the natural dryness of the atmosphere, soon promotes hardness of stem and materially checks growth. In the case of very early Celery it also often leads to bolting prematurely to flower. During the passing summer and autumn early and late-planted Celery like has had ample moisture and cool weather, so that the conditions of growth have been peculiarly favourable. There has been also a marked absence of leaf-mining maggot, and that has been good for the plants. The development of Celery is naturally due largely to the way in which the trenches for its reception have been prepared.

It is amusing to note the great depth to which some trenches are opened, the plants being put out into subsoil which, though manured and well broken up, is none the less poor and devoid of fitness for Celery growth. The better plan by far where good growing soils are shallow and subsoils are of clay, chalk, sand, or gravel, is to throw out from a trench 12 inches to 14 inches wide the top spit of good soil on to one side, and some 8 inches or 9 inches depth of the subsoil beneath on the other side. Then return the top soil to the trench, add and well mix with it a heavy dressing of half-decayed yard manure, and plant the Celery. Where soil is naturally good for one 21 inches to 24 inches deep, the ground being frequently trenched and manured, then his form of treatment is not required. However, if trenches when ready for the reception of plants be from 4 inches to 6 inches in depth, that is ample. The primary objects of planting in trenches are, first, to have a basin which will hold water or liquid-manure; and, second, to economise space between the rows when
